Alternative structures are species in which the azulene system is fused to the benzene ring through its seven-membered ring (azuleno[5,6,7-cd]phenalene) and a structure, similar to II, in which the unpaired electron is located at the other end of the molecule Such species, however, are considered less likely than structure II.

The possible formation of an azulene-type radical is of interest because some simple azulenes readily afford radicals[1] and also because some azulenes have been reported to possess anti-inflammatory[2], anti-pyretic[3], anti-irritant[4] and, possibly, growth inhibiting[2,5] properties The radicals formed seem to be fairly stable in vacuum at temperatures between room temperature and 300° C, however, in the presence of other substances they may react further For example, the radicals formed from benzpyrene combine with air to form a different radical, as judged by a drastically altered electron spin resonance spectrum Confirmation of the proposed structure of the radical, as well as the evaluation of its biological activity, would be made possible by a synthesis of the parent hydrocarbon (II), it is hoped that this communication will encourage the appropriate synthetic work.

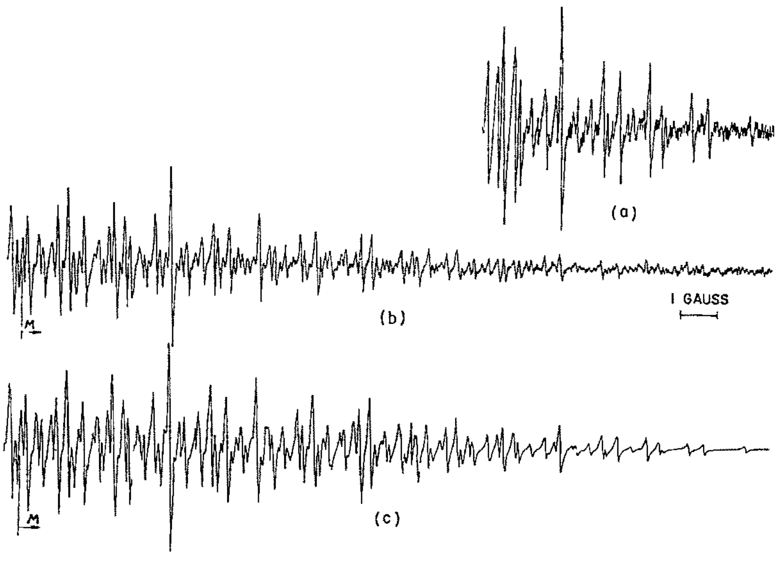

Fig 1 Experimental (*a*, wings under higher gain, *b*, half-spectrum, *M* shows midpoint of spectrum) electron spin resonance spectrum of 3,4-benzpyrene, heated in vacuum to 220° C The computed spectrum, *c*, was obtained with the parameters given in the text and assuming a linewidth of 50 mgauss

The spectra were determined by standard methods on a Varian *E*-3 spectrometer To eliminate the possibility that an impurity might be responsible for the observed spectrum, 3,4-benzpyrene was obtained from several suppliers (Aldrich and Baker) and a zone-refined sample was also used Similar spectra were obtained for each compound on heating

BIOCHEMISTRY

Urinary Hydroxyproline Excretion in Phosphate Depleted Rachitic Rats

THE increased output of hydroxyproline peptides in the urine of patients with osteomalacia[1] has been found to increase still further when the rickets are cured with phosphate[2] Studies using ^{14}C-proline indicate that the hydroxyproline in the urine of growing rats is derived both from recently synthesized soluble collagen and from the catabolism of the mature insoluble collagen fibres[3] The experiments reported here were designed to discover whether the increased excretion of hydroxyproline in healing rickets comes from the synthesis of new collagen.

Weanling Wistar strain male white rats 4 weeks old were divided into two groups, the control group continued on a normal diet and the other was fed a low phosphate diet deficient in vitamin D (ref 4) for 4 weeks The growth rates of both groups were comparable (body weight at 8 weeks normal rats 210 g, rachitic rats 140 g) and florid rickets developed without severe stunting of growth which in itself may induce changes in hydroxyproline output[5] The rachitic rats were divided into two pairs, one pair was re-fed with a diet supplemented with phosphate and the other was maintained on the depleted diet After 2 days on this regime, pairs of normal, re-fed and depleted rats were given 50 μc of ^{14}CU-proline intraperitoneally, placed in metabowls and the expired labelled carbon dioxide and radioactive urine were separated from faeces collected at intervals during the next 48–72 h The animals were then killed, blood was obtained for chemical estimation, and bone and skin were dissected out for analysis The urine was hydrolysed with 6 normal hydrochloric acid at 126° C for 3 h and the chromogens were absorbed onto charcoal, evaporated over potassium hydroxide in a vacuum and chromatographed to separate proline from hydroxyproline[6] The hydroxyproline was extracted and the specific activity estimated[7] in three separate fractions, the mean value being plotted in Fig 2

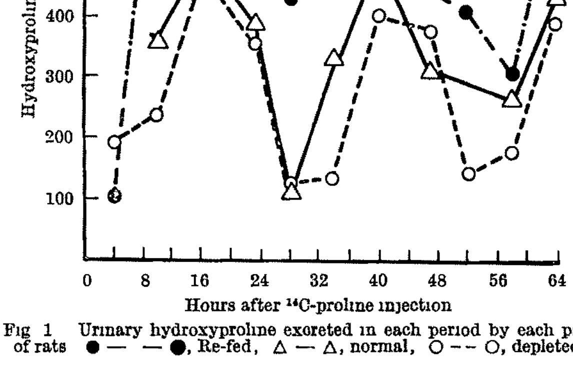

Fig 1 Urinary hydroxyproline excreted in each period by each pair of rats ● — — ●, Re-fed, △ — △, normal, ○ - - ○, depleted

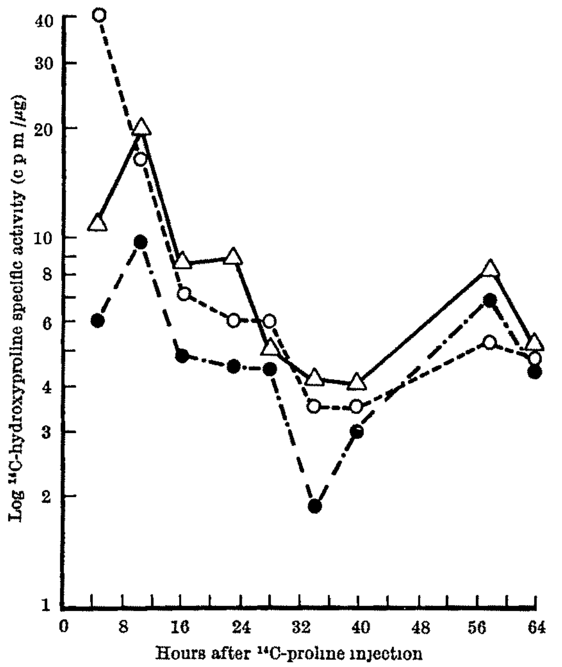

Fig 2 Specific activity of urinary hydroxyproline in each period for each pair of rats. ● — — ●, Re-fed, △ — △, normal, ○ - - ○, depleted

Fig 1 shows the mean excretion of hydroxyproline for each pair of rats during each period (the normal excretion corrected for body weight) and the specific activity of the hydroxyproline excreted in the urine per period is shown in Fig 2 The amounts and specific activity of the labelled carbon dioxide from each group of rats are shown in Table 1 The concentration of calcium in the plasma was normal for all three groups, and low concentration of phosphate in the plasma of the rachitic group was completely corrected in the re-fed group

Table 1 $^{14}CO_2$ EXPIRED BY THE THREE GROUPS OF RATS ABSORBED INTO SODIUM HYDROXIDE

		Carbon dioxide (μmoles/ml)	^{14}C (c p m /ml)	Specific activity (c p m /μmole)
Run I	Rachitic	18 5	360	19 5
	Re-fed	19 6	528	27 0
	Normal	21 0	620	29 5
Run II	Rachitic	15 5	293	18 9
	Re-fed	17 7	319	18 0

The output of hydroxyproline was comparable in the rachitic and normal rats (corrected for body weight) The maintained output in phosphate deficient rats suggests an increased turnover of collagen in this state, which could be linked with the increased number of new osteoblasts formed along osteoid seams[8] On the other hand, secondary hyperparathyroidism, which may occur in osteomalacia, could also increase the resorption of mature collagen[9], however, in our experiments the serum calcium was normal and hyperplasia was not found[10] The higher specific activity of urinary hydroxyproline in the rachitic rats during the first two periods suggests that the urinary output comes from the degradation of recently synthesized collagen, this has also been recorded *in vitro* with chick bone deficient in vitamin D (ref 11) In the re-fed rats the serum chemistry of which had returned to normal and the wet bone weight of which had increased, the specific activity of urinary hydroxyproline scarcely differed from that of normal rats in the first stages, despite the two or three-fold increase in the output of hydroxyproline It seems that increased synthesis is matched by increased resorption in equal proportions Later in the experiment, however, a lower specific activity was recorded as resorption of non-labelled collagen dominated, but fresh synthesis continued from an ever-decreasing pool of labelled proline There was no evidence of different sized proline pools, for total excretion of labelled carbon dioxide derived from proline metabolism did not differ significantly in the three groups of animals Analysis of the tibial metaphyses (Table 2) showed that the specific activity of the collagen 2 days after a single injection of labelled proline was higher in the rachitic than in the re-fed animals, which suggests that the higher formation rates in the latter lead to more labelled collagen after 48 h This suggestion is supported by the higher counts per microgram of decalcified tissue It seems that after 72 h resorption of mature unlabelled collagen in the re-fed rats has raised the specific activity

Table 2 SPECIFIC ACTIVITY OF HYDROXYPROLINE IN TIBIAL BONE 48 AND 72 H AFTER A SINGLE INJECTION OF ^{14}CU-PROLINE

(c p m /μg of hydroxyproline ± *S D*)

Time	Normal	Re-fed	Rachitic
48 h	—	2 4±0 3	3 5±0 3
72 h	5 6±1 9	5 4±0 3	2 5±0 7
c p.m /μg of decalcified tibial metaphyseal tissue			
48 h	—	154±14	310±30

Thus there is evidence of increased collagen turnover in rickets, particularly during healing by phosphate repletion when increased synthesis and resorption take place in almost equal proportions

Effect of Phenylhydrazine and Hydrolysed Glucose Cycloacetoacetate on Adenosinetriphosphatase Activity in Liver Mitochondria

ALTHOUGH freshly prepared liver mitochondria are unable to hydrolyse ATP at a perceptible rate[1], damaging liver mitochondria is known to bring about ATP hydrolysis[2] Deleterious effects of phenylhydrazine on liver have also been reported[3,4]

It has been suggested that the hydrolysed product of glucose cycloacetoacetate plays a beneficial part in the regeneration of hepatic cells damaged by phenylhydrazine[5] This product has been reported to affect alkaline phosphatase activity and the phosphatases involved in glycolysis[6,7] Glucose cycloacetoacetate has also been reported to prevent fatty infiltration of liver[8], and the association of increased ATPase activity with fatty livers is well known[9] We have therefore tried to study the *in vitro* effect of glucose cycloacetoacetate on the ATPase activity of normal mitochondria as well as those incubated with phenylhydrazine hydrochloride

Glucose cycloacetoacetate was prepared by the method of West[10] as modified by Nath *et al* [11] The hydrolysed product was obtained by the procedure of Nath and Nath[12] A solution of recrystallized phenylhydrazine hydrochloride was prepared in redistilled water

The mitochondria from rat liver were isolated in ice-cold isotonic sucrose–versene (0 25 molar sucrose, 0 005 molar versene) by the method of Schneider and Hogeboom[13]. The reaction medium used for the assay of ATPase activity contained 0 075 molar potassium chloride; 0 05 molar sucrose; 0 05 molar *tris* hydrochloric acid buffer (*p*H 7 5), 0 001 molar EDTA, and 0 005 molar ATP The reaction was allowed to continue for 20 min at 26° C and was stopped by the addition of 10 per cent trichloroacetic acid Inorganic phosphate was determined in a sample of the solution by the method of Fiske and Subba Row[14] The results are presented in Table 1

Table 1 EFFECT OF PHENYLHYDRAZINE AND GCAh ON ATPase ACTIVITY OF NORMAL MITOCHONDRIA *in vitro*

Substances added	ATPase activity (μmoles of inorganic phosphate/mg of protein/ 20 min and *SEM*)	Activity increase (per cent)
(1) None	22±0 2	—
(2) Phenylhydrazine	84±0 1	282
(3) GCAh	16±0 4	−27
(4) Phenylhydrazine plus GCAh	39±0 5	77

GCAh, glucose cycloacetoacetate.
All estimations were carried out in triplicate The concentration of phenylhydrazine and GCAh in the final reaction medium was 3 mg The mitochondria were incubated with the assay medium for 30 min before addition of substrate (ATP)

These results show that the activity of ATP in normal hepatic mitochondria is enhanced by phenylhydrazine, which adversely affects the liver This may enhance the enzyme activity like other liver damaging substances such as carbon tetrachloride[9] Furthermore, data show that hydrolysed glucose cycloacetoacetate markedly lessens the enhanced activity of the enzyme caused by phenylhydrazine The hydrolysed product of glucose cycloacetoacetate has also been found to lower the activity of ATPase in normal mitochondria Nath and Prasannan had suggested that glucose cycloacetoacetate is involved in the regeneration of hepatic cells damaged by phenylhydrazine[5]

Conversion of δ-Amino Laevulinic Acid to Porphobilinogen by Different Tissues of the Polychaete Annelid *Neoamphitrite figulus*

THE heart-body, a small spongy mass of tissue within the dorsal vessel of the terebellid polychaete *Neoamphitrite figulus* (Dalyell), is almost certainly concerned with synthesis of the haemoglobin of the blood The coelomocytes also contain haemoglobin, but this is different Kennedy and Dales[1] have shown that the heart-body tissue and the coelomocytes in this species converted porphobilinogen (PBG) to uroporphyrin Tissues were incubated with purified PBG suspended in sea water and at room temperature for varying periods and the products identified after extraction and purification by paper chromatography Some similarly performed experiments using δ-amino laevulinic acid (ALA) did not give clear results Subsequent work, using the method of McRae[2], whereby the conversion of ALA to PBG is identified against suitable controls by the positive reaction PBG gives with Ehrlich's *p*-aminobenzaldehyde reagent[3], has, nevertheless, given quite clear results McRae's method was followed in detail except that to quantify the results the tissues were merely dried with acetone and weighed, for it was desired only to compare the relative ability of different tissues to convert ALA to PBG McRae used homogenates of whole animals (*Dugesia*) Tissues were deep frozen and homogenized on thawing in M/15 phosphate buffer, *p*H 7 0, the ALA being added to provide a concentration of 400 μg/ml of homogenate Homogenates, suitably controlled, were incubated at 37° C for 2 5 h The colour of the Ehrlich reaction was measured at 553 mμ after 15 min with a 'Unicam *SP* 500' spectrophotometer. While the activity of each tissue is expressed in arbitrary units, their relative activities in one typical experiment are shown in Table 1 The experiment was repeated five times with similar results The tissues of five worms were pooled in each experiment Table 1 shows that the heart-body is ten times more active than any other tissue determined The body wall muscle is colourless and if it contains any myoglobin this is in a relatively low concentration and any ALAase present is insufficient to produce enough PBG to be detected by the method On the other hand, Kennedy and Dales[4] detected coproporphyrin III, which must have been formed during haem synthesis, in the body wall, whether this is formed in the skin or is deposited there, as this negative result suggests, is being investigated further The hind stomach or gizzard has muscles of a deep red colour and some ability to convert ALA to PBG is not surprising The ability of the coelomocytes to do so is also expected, confirming the hypothesis that they synthesize their own haemoglobin from ALA and do not receive compounds later in the biosynthetic pathway to haem The high activity of the gut (fore stomach plus intestine) from which the contents had carefully been removed is surprising, especially because Kennedy and Dales[4] found no free porphyrins in these tissues It may be that the coelomocytes, which contain haemoglobin, arise from the coelomic epithelium of the gut wall. This is being investigated further

Table 1 CONVERSION OF ALA TO PBG BY DIFFERENT TISSUES OF *Neoamphitrite figulus*

Tissue	Weight of tissue (mg)	Activity (arbitrary units/ mg of tissue)
Heart-body	1 8	89 00
Coelomocytes	64 9	8 50
Fore stomach + intestine	39 6	7 82
Hind stomach (gizzard)	58 0	4 08
Body wall	177 5	0 00
Blood	7 9	0 00

I wish to thank Miss Jennifer Pell for collecting the specimens used

Measurement and Significance of Weight Heterogeneity in Some Protein and Polysaccharide Preparations

MOST of the molecular weight values reported for macromolecules have been obtained by methods based on ultracentrifuge measurements Many biologists and biochemists now have access to an analytical ultracentrifuge and their requirements can be satisfied by sedimentation velocity experiments

Although macromolecules may sediment at similar rates and produce sharp boundaries, it is sometimes forgotten that this does not necessarily imply homogeneity of the system Thus serum transferrins produce a single symmetrical boundary in ultracentrifuge experiments whereas under electrophoresis the proteins may be resolved into two or more discrete fractions, depending on the animal species The transferrins may also exhibit some degree of association, for reported molecular weights of the transferrins[1,2] of several species are between 66,000 and 90,000 The discrepancy in the reported molecular weights is of some clinical importance because it affects the reliability of iron binding measurements Polysaccharides such as glycogen and amylopectin produce sharp boundaries as a result of the very large concentration dependence of the sedimentation coefficient[3] These polysaccharides possess a very broad distribution with respect to sedimentation velocities Several methods have been proposed in the past twenty years for the quantitative measurement of weight heterogeneity In 1944, Gralén[4] proposed that the width of the sedimenting boundary was an index of heterogeneity More recently, Baldwin[5,6] and other workers have made detailed analyses in which the complete distribution curve of the sedimentation coefficients is evaluated (compare Schachman[7]) Other more basic factors are often ignored, regardless of the method selected for quantitation of heterogeneity Quite often the criteria of purity applied to the preparation are not sensitive enough to justify detailed mathematical analysis of the boundaries The preparations may also undergo physicochemical changes during the experiment[8] so that control experiments are essential

We have been studying changes in the catabolic heterogeneity and weight heterogeneity of serum 7*S* gamma globulins in mouse and man after immunization with various antigens, including malignant tumours Electrophoretically distinct fractions of 7*S* gamma globulin are broken down at different rates in the mouse[9,10] and signi-

Table 1 MOLECULAR WEIGHT AVERAGES AND HETEROGENEITY OF GAMMA GLOBULINS FROM NORMAL AND IMMUNE MICE

Immunizing tumour	M_w	M_z	M_z/M_w
None	162,000	179,000	1 10
Leukaemia	194,000	317,000	1 63
Epithelioma	221,000	349,000	1 58
Mammary	157,000	239,000	1 52

ficant changes in these catabolic rates have been observed in mice immunized with transplantable tumours[9] These findings are clinically important because there is now evidence that heterogeneity of both function and antigenicity in the 7*S* gamma globulins of certain experimental animals may correlate with immunological tumour enhancement[11]

Ultracentrifuge experiments showed an increased weight heterogeneity of mouse 7*S* gamma globulin following immunization with transplantable homologous tumours when compared with 7*S* gamma globulins from non-immunized mice, measured under identical conditions[12] In these experiments, short columns of 7*S* gamma globulin solutions were centrifuged to sedimentation equilibrium in double sector cells The values of the molecular weight averages M_z and M_w were computed by the method of Van Holde and Baldwin[13] and the ratio of these values, M_z/M_w, provided a measure of the weight heterogeneity in the system Immune preparations gave significantly greater M_z/M_w ratios than those for normal gamma globulin preparations (Table 1), indicating that they were much more heterogeneous The immune gamma globulins contained a proportion of molecules with weights greater than 400,000, suggesting that those were aggregated forms of 7*S* gamma globulin There may be a correlation between increased weight heterogeneity and changes in catabolic heterogeneity of mouse 7*S* gamma globulin The recent observation[14] that human 7*S* gamma globulin possesses catabolic heterogeneity, apparently analogous to that of mice, suggests that similar weight heterogeneity changes might also be observed

Reported molecular weight values of the 7*S* gamma globulins of several species range from 130,000 up to 195,000 (ref 15) Pain[16] has recently investigated the problem of gamma globulin heterogeneity using horse 7*S* gamma globulin He found that the preparation was essentially homogeneous according to size, but his experiments did not include 7*S* gamma globulin from immunized animals

A study of the molecular weight distributions in human 7*S* gamma globulin samples from normal and pathological subjects might well yield information of clinical importance The technique of measuring weight heterogeneity in terms of the relative M_z and M_w average molecular weights is, however, unsatisfactory in view of the large number of measurements which would have to be made for these observations to have statistical significance A simple method is required which can be used routinely and which exposes the protein to the least physical change *in vitro* An obvious method seemed to be to measure the degree of departure from the theoretical Gaussian curve of the observed Schlieren diffusion pattern, a method which was first reported by Gralén[4], who measured D_M and D_A for various derivatives of cellulose and used the ratio D_M/D_A as a measure of heterogeneity The diffusion coefficients D_M and D_A were obtained from plots of $\sigma_M{}^2$ (the square of the standard deviation of the experimental curve) and $\sigma_A{}^2$ (determined by the height area method) plotted respectively against time

The behaviour of mixtures of albumin monomer and dimer was examined in order to determine the limitations of this technique experimentally The monomer and dimer samples used were obtained by fractionation of a commercial albumin preparation (Behringwerke A G , Marburg, Lahn) through 'Sephadex *G* 150'

Diffusion experiments were carried out in synthetic boundary cells in an MSE analytical ultracentrifuge (Measuring and Scientific Equipment, Ltd , London) Boundaries were produced at slightly higher speeds (15,000 r p m , 16,000*g*) than those normally used for diffusion experiments, in solutions containing 6–7 mg of protein/ml Photographs of the diffusion patterns were taken on 35 mm film at suitable intervals of time, and tracings of enlargements (× 24) of these were then made on graph paper Values of $\sigma_M{}^2$ and $\sigma_A{}^2$ were computed from measurements of the ordinates at suitable intervals on either side of the maximum point (the mode) of individual enlargements

Although the diffusion patterns of the original albumin preparation showed considerable asymmetry, presumably due to the presence of tetramers and pentamers, mixtures of monomers and dimers showed no asymmetry Further, the plots of $\sigma_A{}^2$ against time were linear, indicating homogeneity. Replacement of dimer in the mixture with an equal amount of 7*S* gamma globulin produced marked asymmetry of the diffusion curve and produced positive deviation from linearity of the $\sigma_A{}^2$ against time plots

The diffusion coefficients showed a roughly linear relationship to the composition of the mixture, but the ratio, D_M/D_A, provided little evidence of heterogeneity in the monomer–dimer systems (Table 2) Monomer–dimer interactions in 7*S* gamma globulin systems would be expected to be analogous to albumin, and so the method is unlikely to be useful for measuring heterogeneity in these systems

Table 2 RELATIONSHIP BETWEEN MOLAR COMPOSITION OF THE ALBUMIN MONOMER–DIMER MIXTURE AND DIFFUSION CHARACTERISTICS

Percentage monomer	$D_{20,w}$ (× 10^7 cm² sec⁻¹)	D_M/D_A
100	5 80	0 98
70	5 40	0 98
20	4 90	0 95
10	4 37	0 94
0	4 33	0 96
Commercial albumin	4 11	0 81

The D_M/D_A index seemed to be of some value in preliminary studies made of relative molecular distributions in glycogen preparations from various tissues These glycogens, which have $S^0{}_{20,w}$ values of 70–80*S*, show appreciable sedimentation velocity at 15,000 r p m so that the analysis is really of the sedimentation boundary Du Pont de Nemours (Wilmington, Delaware) have recently introduced an analogue computer, the 310 'Curve Resolver', for resolving overlapping peaks This instrument, which analyses the experimental curve in terms of its simplest composition using any preset curve distribution, may be of value for the rapid analysis of the asymmetric boundaries produced by glycogen and similar macromolecular substances The analysis of the Schlieren pattern of shell fish glycogen (D_M/D_A ratio 1 25), assuming pure Gaussian distributions, is shown in Fig 1 At

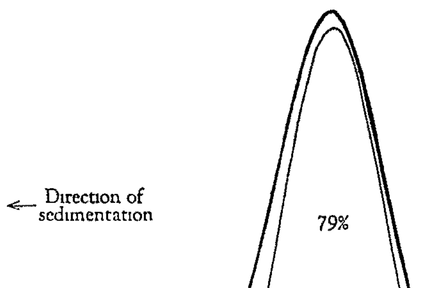

Fig 1 The broad outer line is the Schlieren profile of shell fish glycogen sedimenting at 16,000*g* The inner curves show the position and relative proportions of three components as indicated by the 310 'Curve Resolver'

least three components are present in this preparation and their relative proportions are indicated Such analysis might possibly be used to investigate metabolic disorders in liver in terms of distribution changes in the synthesized glycogen

The recent introduction of the monochromatic light scanning system has now made it possible to record ultracentrifuge data directly in a form suitable for computer analysis[17] This technique may well become the accepted way of measuring molecular weights and finally provide a general procedure for characterizing heterogeneity.

We thank Dr D B. Gammack for some of the ultracentrifuge measurements and Dr G A Gilbert for helpful discussions This work was supported by the British Empire Cancer Campaign for Research

MICROBIOLOGY

Photosynthetic Bacterium growing under Carbon Monoxide

OXIDATION and utilization of carbon monoxide by bacteria have often been observed[1–4] The metabolism of these bacteria was assumed to be chemolithotrophic because of the absence of any added organic energy source

The enrichment and growth of carbon monoxide oxidizing bacteria were enhanced if the culture was kept under continuous illumination, an effect which might be a result of photoreversal of the binding of carbon monoxide to a cytochrome *c* oxidase (my unpublished results)

Photosynthetic bacteria growing under carbon monoxide have been accidentally discovered in enrichment cultures for carbon monoxide oxidizing bacteria Forty-three strains of various genera of these bacteria were purified by streaking illuminated enrichment cultures (30–70 per cent carbon monoxide) on mineral salts agar contained in 'Dispo' plates (medium 337 of Hirsch and Conti[5], without carbon source, but with 0 01 per cent yeast extract added) Incubation was under incandescent light and at room temperature, in desiccators containing an atmosphere of 70 per cent carbon monoxide, 20 per cent oxygen, 1 per cent carbon dioxide and 9 per cent nitrogen Growth of the aerobic carbon monoxide bacteria ceased after several weeks probably because of lack of oxygen Red pigmented colonies then appeared on several plates Microscopic examination revealed photosynthetic bacteria strikingly similar to *Rhodopseudomonas* spp (Fig 1) The rod or club-shaped cells often had side branches and/or swellings on both ends, budding cells were observed frequently in any population Budding of different *Rhodopseudomonas* spp has been recently investigated[6]

These purple bacteria were purified easily by streaking on the same medium and incubating under the atmosphere of carbon monoxide+oxygen+carbon dioxide+nitrogen in the light Growth became abundant only after other carbon monoxide bacteria had removed the oxygen from the gas mixture, as is evident from manometric measurements as well as from tests with alkaline pyrogallol solution

The enrichment and isolation procedure was repeatedly successful with either garden soil (podsolic, *A*-1 layer, *p*H 6 8) or sewage mud (shore of New Haven, Connecticut harbour, *p*H 7 2) as the inoculum Several weekly gas changes seemed to be advantageous and helped to build up the population of carbon monoxide dependent bacteria

Pure cultures of these purple bacteria grew well anaerobically in the light in media normally used for *Rhodomicrobium vannielii*[7], with sodium acetate or sodium lactate as the hydrogen donors Growth on mineral salts agar under carbon monoxide and in the light was slow but abundant The absence of any added organic carbon or hydrogen source as well as lack of hydrogen sulphide was accomplished by employing gases and chemicals of highest available purity (Matheson Comp, Fisher's and Baker's reagent grades, Difco Noble agar, washed) All glassware was cleaned with acid after detergent had been used, and the desiccators were sealed with Dow Corning high vacuum silicone lubricant, with negligible vapour pressure Rubber tubing was excluded

In these conditions, light, carbon monoxide and ammonium ions seemed to be the only sources of energy available, either carbon monoxide or carbon dioxide or both would have to serve as the source of carbon Oxidation of ammonia could not be detected, and thus water cleavage must render an available form of hydrogen for these photolithotrophic bacteria The small increment of yeast extract could be left out with little or no effect on the total growth yield

Recently, *Rhodopseudomonas* spp have been reported to utilize ("photo-oxidaze") C1 compounds such as formate[8] and possibly methane (personal communication from W Vishniac) Utilization of carbon monoxide by a photosynthetic bacterium could be taken as another demonstration of the versatility of members of this group Further investigations will involve the use of labelled

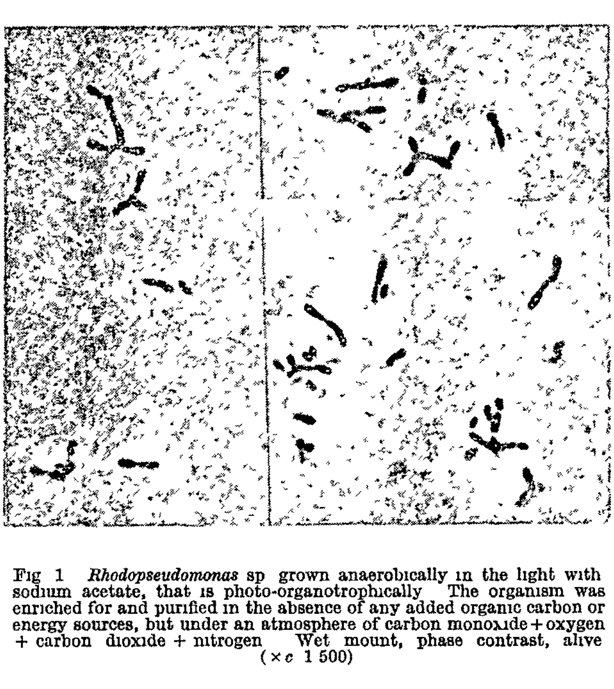

Fig 1 *Rhodopseudomonas* sp grown anaerobically in the light with sodium acetate, that is photo-organotrophically The organism was enriched for and purified in the absence of any added organic carbon or energy sources, but under an atmosphere of carbon monoxide+oxygen + carbon dioxide + nitrogen Wet mount, phase contrast, alive (×c 1 500)

Competitive Binding of Streptomycin and Magnesium with *Escherichia coli* Ribosomes

SEVERAL laboratories have presented evidence that streptomycin inhibits protein synthesis of sensitive bacteria[1-4] Studies with cell free systems have clearly shown that the 30*S* sub-unit of the ribosomes derived from streptomycin-sensitive cells is the site of action of this antibiotic[5-8]. It has also been shown that one to two molecules of streptomycin bound to one ribosome particle suffice to exert an inhibitory effect on polypeptide synthesis[9,10]

Streptomycin contains the diguanido base, streptidine, and it has been shown to combine with nucleic acids to produce a polymeric compound which is dissociable in 1 molar sodium chloride in like manner to thymic nucleohistone or nucleoprotamine[11] When dihydrostreptomycin (DHSM) is converted to dideguanyldihydrostreptomycin (DGSM), the net cationic charge of DHSM is decreased from 3+ to 1+ without other detectable structural change[12]. This modified compound does not have any biological effect on streptomycin-sensitive *E coli*, suggesting that the biological activity of streptomycin is primarily related to the cationic groups[12,13] In fact, it has been suggested by some investigators that the observed effects of streptomycin in bacterial systems are the result of competition of streptomycin with Mg^{2+} (and polyamines) for a critical site or sites on the ribosome[8,14,15].

We have studied the cation exchange properties of *E. coli* ribosomes and have shown that small cations (K^+, NH_4^+, spermidine^{3+}, spermine^{4+}) can compete with Mg^{2+} for the anionic binding sites but to a variable degree[16] It has also been shown that there is no difference in the ion binding capacities between the 30*S* and 50*S* sub-units of the ribosomes In a further effort to relate the cation exchangeability of streptomycin to its biological effect, we therefore examined the possibility of a competitive effect between the antibiotic and Mg^{2+} bound to the ribosomes isolated from streptomycin-sensitive *E coli B*

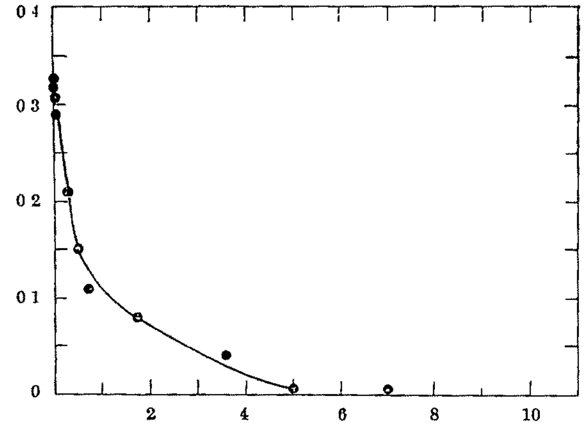

Fig 1 Effect of streptomycin on Mg^{2+} binding to *E coli* ribosomes in the presence of 10^{-2} molar *tris* buffer (*p*H 7 4)

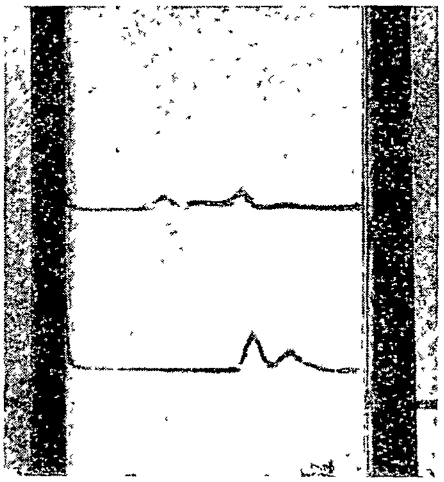

Fig 2 Analytical ultracentrifuge pattern of *E coli* ribosomes showing changes in ribosomes when one-half of the Mg^{2+} is displaced by streptomycin The lower pattern represents the 30*S* and 50*S* ribosomes in 10^{-2} molar *tris* buffer (*p*H 7 4) containing 5×10^{-5} molar Mg^{2+} The upper pattern represents the same ribosomes to which have been added $6\ 25 \times 10^{-4}$ molar streptomycin

A mixture of the 30*S* and 50*S* sub-units was prepared from *E coli B* as described by Tissieres *et al* [17], and a 0 1 per cent suspension of the ribosomes was made in 10^{-2} molar *tris* buffer, *p*H 7 4, containing 5×10^{-5} molar magnesium acetate. The change of Mg^{2+} binding to the ribosome in the presence of various concentrations of streptomycin sulphate (Nutritional Biochemicals Corporation, Cleveland, Ohio) was measured by means of equilibrium dialysis The details of our technique have been described before[16] As shown in Fig 1, the amount of Mg^{2+} bound to the ribosome decreased markedly when the concentration of streptomycin was increased, indicating that the antibiotic can displace Mg^{2+} on the binding sites of the ribosomes When the ribosomes from which the bound Mg^{2+} had been partially displaced by streptomycin were examined by the analytical ultracentrifuge, they were not the usual mixture of the 30*S* and 50*S* ribosomes (Fig 2) The ribosomes in the presence of 0 625 mmolar streptomycin showed a quite different picture of aggregation from that of the ribosomes to which streptomycin was not added This result indicates that a considerable change takes place in the ribosomal structure when half of the bound Mg^{2+} is displaced by streptomycin

Spotts and Stanier[18] proposed a hypothesis that streptomycin prevents a strand of messenger RNA from attaching to the ribosome of streptomycin-sensitive bacteria It has also been shown that messenger RNA is released from the ribosomes at a very low concentration of Mg^{2+} [19,20] The inhibitory effect of streptomycin on polyuridine-directed ^{14}C-phe-*t*RNA binding to the ribosomes is competitively relieved by increasing the concentration of Mg^{2+} in the solution[9,19] Studies with artificial polyribosomes suggest that the inhibitory effect of streptomycin is related not to the formation of polyribosomes but to the interference with the function of polyribosomes[8,9,15,21,22] This perturbation of the function of polyribosomes which is revealed by specific alteration of the recognition process of codons is also related to the concentration of Mg^{2+} and NH_4^+ in the amino-acid incorporation system Furthermore, the inhibitory effect of streptomycin is partially relieved when polyamines like spermine and spermidine are added to the cell free system containing *E coli* ribosomes[14] This antagonistic relationship between streptomycin and various cations has also been demonstrated *in vivo*, as reflected by induction of β-galactosidase[13] But the concentration of streptomycin employed in the studies of its inhibitory effect on the cell free amino-acid incorporation into protein (that is, approximately 0 1 mmolar) was considerably lower than that used in our experiment The change of sedimentation pattern of the ribosomes in the presence of 0 625 mmolar streptomycin may be an exaggerated picture of a more subtle configurational change which may occur at a lower concentration of streptomycin (that is, 0·1 mmolar) It would be very interesting to see whether the same result could be obtained in a similar experiment with the ribosomes from streptomycin-resistant *E coli*

IMMUNOLOGY

Erasure of Immunological Memory with Anti-lymphocyte Serum

Levey and Medawar[1] have reported that treatment with anti-lymphocyte serum (ALS) can restore "virgin" reactivity to mice which have been previously sensitized by skin homografts across H-2 barriers Confirmation of this finding has not yet been published, and some authors[2] have failed to reproduce erasure of memory in similar experimental models

I have studied this phenomenon in three separate experiments In the first one, mice were made immune to a protein antigen In the other two experiments, skin was transplanted, the donors differing from the recipients at the H-2 locus

ALS was raised in rabbits to mouse thymocytes according to the method of Levey and Medawar[3] and was administered subcutaneously to *CBA* mice A total of 2 0 ml. of ALS was given to each experimental animal 0 5 ml followed by 0 25 ml × 6 on alternate days Controls received normal rabbit serum (NRS) in equivalent dosage and at the same time intervals *CBA* mice were made immune to bovine serum albumin (BSA) by the intraperitoneal injection of 5 mg of BSA in saline and were challenged by a second intraperitoneal injection of 100 μg of BSA Mouse sera were collected 10 days after challenge and were analysed for the presence of precipitating antibodies to BSA by a modification of the Farr technique[4]

CBA mice were sensitized to transplantation antigens by *A* strain tail skin grafts according to the method of Billingham and Medawar[5] Challenge with a second *A* strain skin graft was performed at varying intervals after immunization Skin grafts were inspected daily from the seventh day onward until rejection occurred Life tables were constructed for the various groups

In all experiments the time between initial immunization, serum treatment and subsequent challenge was systematically varied The protocols for the three experiments are shown in Tables 1, 2 and 3. The results which were obtained after immunization with BSA are summarized in Table 1 In no case had reversion to an immunologically "virgin" state been accomplished with ALS treatment All animals responded to challenge with titres above those which are characteristic of the primary response In two groups (B and H) the response of animals which had been treated with ALS was significantly lower than that of the corresponding controls which had been treated with NRS None the less, the response in all animals must be viewed as a secondary response because the challenge dose of 100 μg of BSA would not be expected to provoke a detectable response by this technique when given to *CBA* mice *de novo*[6]

In experiments 2 and 3, *CBA* mice were allowed to reject first-set *A* strain tail skin grafts before ALS was administered (Tables 2 and 3) The ALS which was administered in experiment 2 was of only moderate

† Either ALS or NRS administered subcutaneously 0 5 ml , then 0 25 ml × 6 on alternate days

MST, mean survival time

strength The formal assay of this antiserum yielded a mean survival time of skin homografts (*A* → *CBA*) of 23 days The ALS used in experiment 3 was considerably more potent (MST 30 days) In experiment 2 (Table 2), the mean survival times of second set grafts on animals which had been treated with ALS fell between those characteristic of first and second set rejection The most rapid rejection of challenge homografts was found in the NRS control group Thus, although the secondary response would have been modified, the animals which had been treated with ALS still gave some evidence of earlier sensitization

Table 3 EFFECT OF ALS ON CBA MICE SENSITIZED TO *A* STRAIN SKIN

Group	No of animals	Interval between ALS treatment and challenge* (weeks)	Fate of second skin graft MST (days)	Fate of second skin graft Range (days)
A	9	0	39 5	23 5–55 5

C	9	6	11 2	9 5–12 5
D	9	10	11 5	8 5–16 5
Primary response	46	—	10 5	7 5–15 5

All animals received an *A* strain skin graft and 2 weeks later began ALS treatment by subcutaneous injection of 0 5 ml , then 0 25 ml × 6 on alternate days

MST, mean survival time

* Relative to commencement of ALS treatment

The findings in experiment 3 are quite different (Table 3) Regardless of the time which elapsed between ALS treatment and challenge by a second set graft, no animal reverted to a sensitized state (Fig 1) Challenge homografts survived longest when applied near the beginning of ALS administration, thus confirming the remarkable ability of ALS to overcome the sensitization which was aroused by homografts As the interval between serum treatment and challenge increased, the survival time of the second graft decreased By 6 weeks the rate of rejection of the second grafts equalled that of the first set Despite increase of the interval to 10 weeks no further curtailment of survival was found, and in no case did reversion to a sensitized state occur A time interval of 10 weeks should have been more than sufficient to allow complete recovery from the effects of ALS administration[7]

The results obtained in experiment 3 thus fully confirm the findings of Levey and Medawar[1] Memory of a previous sensitization to transplantation antigen was ablated, and with recovery of immunological capacity the animals reverted to a non-sensitized state, rejecting skin grafts at a rate characteristic of the primary response Failure to achieve this result in experiment 2 was probably the result of inadequate treatment with a less potent antiserum

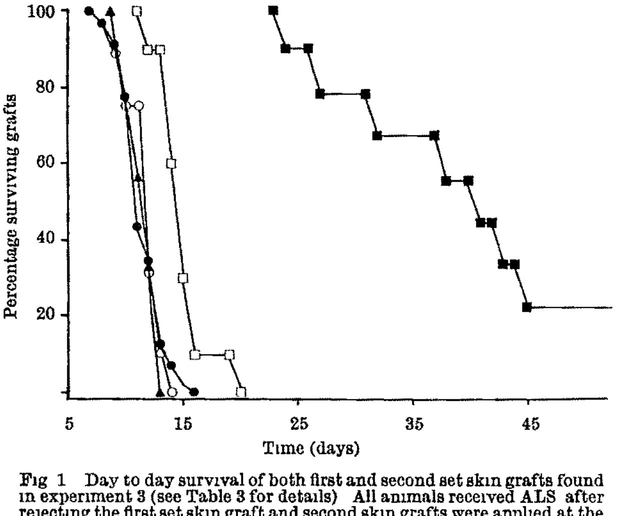

Fig 1 Day to day survival of both first and second set skin grafts found in experiment 3 (see Table 3 for details) All animals received ALS after rejecting the first set skin graft and second skin grafts were applied at the intervals shown relative to the commencement of ALS treatment First set, ● Second set ■, 0 weeks, □, 2 weeks, ▲, 6 weeks, ○, 10 weeks

The failure to erase "memory" of immunization with BSA must be viewed differently The explanation cannot be simply one of inadequate treatment because the potencies of antisera used in experiments 1 and 3 were comparable Furthermore, my experience with other systems (unpublished observations) (*S typhi* "H" antigen and sheep red blood cells) has indicated an extraordinary resistance of the secondary antibody response to the effects of ALS (ref 8) This distinction could reflect the different natural histories of the cells involved in the two types of transactions

Levey and Medawar[9] have shown that the primary action of ALS is on peripheral lymphocytes We have confirmed this view (unpublished observations) and have suggested that the immunosuppressive action of ALS results from the progressive depletion in the host of the pool of circulating small lymphocytes[7] In a skin graft system the responding cells leave central lymphoid tissue and travel to the graft site The pace of graft rejection presumably depends on the proportion of cells "programmed" to respond to the foreign antigens encountered in the graft[10,11] Previous sensitization increases the relative number of circulating cells which are capable of reacting with graft antigens Prolonged treatment with ALS eliminates the population of circulating cells and the regenerating population assumes the original (before sensitization) immunological capabilities which are characteristic of the animal In humoral immune systems the effector cell does not migrate out of the central lymphoid tissue and thereby receives a measure of protection from the effects of ALS When a second dose of antigen arrives at the lymph node or spleen, there remains an enriched population of cells capable of responding While there may be other differences between the primary and secondary response such as the interposition of the macrophage, these need not be invoked to explain the differences which have been observed

Stem-cell Inactivation in Mixed Spleen Cell Cultures

A NUMBER of attempts have been made to understand the interactions possible between immunologically active cells *In vitro*, transformation of lymphocytes in response to other antigenically different lymphocytes has been noted[1] as have similar reactions involving cells explanted from spleens[2] The reactions of immune lymphocytes with their target cells have often been studied The work of Hellstrom *et al* [3] has led to consideration of the notion of allogeneic inhibition during which it is implied that the activity of a cell may be inhibited simply by the presence of a foreign cell antigen All such work is relevant to an

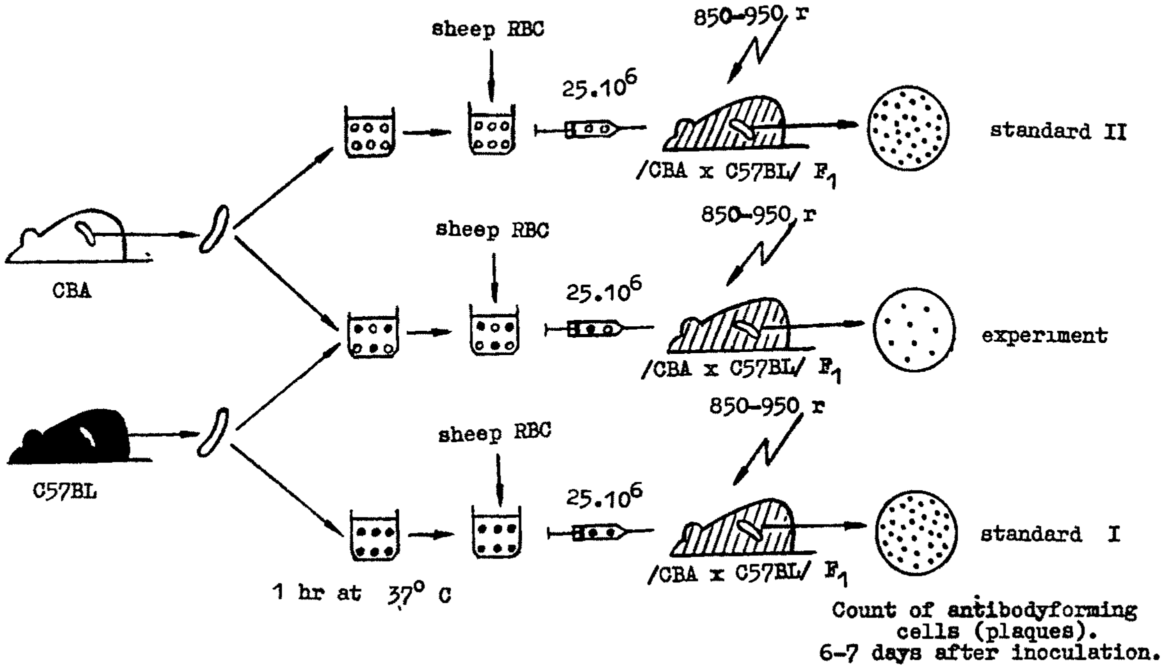

Fig 1 Experimental schedule for the demonstration of stem cell inactivation as adjudged by Jerne plaque count following *in vitro* incubation of mixtures of spleen cells before their injection into irradiated recipients

increase in our understanding of the possible importance of immunological reactions between cells *in vivo* These experiments describe the effects of the presence of foreign cells on the capacity of mouse spleen cells, first to respond to antigenic stimulation, and second to give rise to haematopoietic cell colonies The effect of irradiation on one of the components of the cell mixture is described A preliminary account of this method has already been published[4]

The experimental schedule is laid out in Fig 1 Spleen cells from either *C57Bl* or *CBA* adult mice of either sex were suspended in medium 199 and after two washings in the same medium were resuspended Samples were taken for a dye-exclusion (trypan-blue) test for cell viability The cell density was adjusted to 50×10^6 viable cells/ml The cell suspensions were then incubated separately, or mixed together (50 50 ratio), for 1 h at 37° C At the end of the period of incubation the cells were injected intravenously into irradiated $(C57Bl \times CBA)F_1$ hybrid mice. In those experiments in which we wished to study the immune response of the recipient, sheep cells were added to the spleen cell suspensions before their injection into the irradiated mice 7×10^7 sheep erythrocytes were injected into each recipient At various times after radiation, between the sixth and eighth day, the recipient mice were killed and either direct Jerne plaque assay[5] or spleen colony counts[6] were made In two experiments, *CBA* spleen cells were irradiated *in vitro* with 10,000 r before incubation and transfer All irradiations were effected with gamma-rays

The results are given in Tables 1 and 2 From Table 1 it can be seen that *CBA* and *C57Bl* cells differ in their capacities to react to sheep red cells in irradiated F_1 recipients Furthermore, incubation of the two cell types together seems to result in considerable inactivation of their immunological potential Comparison of the expected with the actual result gives an inactivation index by which different degrees of inactivation may usefully be compared The figure quoted of 75 per cent has been found to be reproducible over a number of experiments Table 2 shows that a similar result is obtained when spleen colonies are counted In this case, however, the *C57Bl* cells have a better capacity than *CBA* cells for responding to the haematopoietic depletion in the irradiated mouse Inactivation of haematopoiesis follows incubation of the two spleen cell types together This inactivation should be thought of as impairment of the activity of haematopoietic stem cells, for there is evidence that spleen colonies are clones It is noteworthy that the inactivation index is similar when measured by estimation of immunologically or haematopoietically active cells

The experiments which involved irradiation of the *CBA* cells must be regarded as preliminary because of the small numbers of mice involved They both, however, give the same result, which suggests that inactivation requires the active participation of both the component cell types in the mixture On this basis, the inactivation phenomenon may be distinguishable from allogeneic inhibition

These experiments show that the interaction between two genetically different mouse spleen cell populations *in vitro* leads to diminution in the capacity of one or other and probably both to respond to antigenic stimuli and to function as sources of haematopoietic stem cells The fact that the inactivation process is initiated and

Table 1 MEAN NUMBER OF PLAQUE-FORMING CELLS PER MILLION SPLEEN CELLS OF $(CBA \times C57Bl)F_1$ MICE 6 (EXPERIMENT 2) OR 7 (EXPERIMENT 1) DAYS AFTER 900 R AND INJECTION OF VARIOUS KINDS OF SPLEEN CELLS

Use of Horse Anti-pig Leucocyte Serum to suppress the Homograft Reaction in Pigs

Interest in the use of heterologous anti-leucocyte serum as a means of suppressing the homograft reaction was stimulated by the work of Woodruff and Anderson[1,2], who showed that rejection of skin allografts in rats could be delayed by administering rabbit anti-rat leucocyte serum to the skin graft recipients Similar findings pertaining to allografts of skin in mice have since been reported by Monaco *et al* [3] and Levey and Medawar[4].

This communication reports preliminary observations on the value of horse anti-pig leucocyte serum in suppressing the rejection of skin allografts in pigs

Two horses were immunized with a cell suspension in Medium 199 (Glaxo) obtained by gently grinding fragments from the mesenteric lymph nodes of outbred pigs, using a hand operated glass piston blender The cell suspension was washed by centrifugation at 580*g* for 5 min and resuspended in fresh Medium 199

Table 1 TIME, IN DAYS, TO COMMENCEMENT OF SKIN ALLOGRAFT REJECTION IN UNTREATED PIGS AND PIGS RECEIVING NORMAL HORSE OR HORSE ANTI-PIG LEUCOCYTE SERUM

Category	Dose of serum	Individual values	Mean
No treatment (group 1 two pigs)		6 8 8 10 7 7 10 10	8·3
Normal horse serum (group 2 two pigs)	3 0 ml /kg body weight/day, intravenously	6 6 7 7 7 7 7 9	7 0
Anti-leucocyte serum (group 3 two pigs)	0 75 ml /kg body weight/day, intravenously	6* 8* 10* 10* 8 8 10 8	8 5
Group 4 two pigs	1 5 ml /kg body weight/day, intravenously	>21 18 18 14 17 >21 18	>18 1

* Received ALS from horse 1. The other pigs in groups 3 and 4 received ALS from horse 2

Horse 1 received three intravenous injections, each of 1×10^9 cells, at intervals of 7 days, and 4 l. of whole blood was taken from it 7 days later After a further 24 days the horse was given another injection of $0\ 44 \times 10^9$ lymph node cells and a further 3 5 l of blood was taken 7 days later

Horse 2 received three intravenous injections at intervals of 7 days, the injections being of 1×10^9, $1\ 7 \times 10^9$ and $1\ 86 \times 10^9$ cells. This horse was bled to give 5 0 l of blood after a further 7 days

The blood was allowed to stand at room temperature for approximately 2 h and was then stored overnight at 4° C The serum was separated after centrifugation at 1,800*g* for 10 min and absorbed, using one-third of its volume of packed pig erythrocytes, at 37° C for 1 h and then overnight at 4° C The serum was again separated after centrifugation at 1,800*g* for 10 min, sterilized by Seitz filtration and stored at − 20° C

Normal horse serum was obtained by bleeding a non-immunized horse and processed as before except that absorption against pig erythrocytes was omitted

Each pig studied received two skin autografts and four skin allografts Skin grafting was carried out as described by Jaffe *et al* [5] with the exception that the grafts were made larger, 1 in.^{2}, to facilitate the recognition of early thickening

The pigs were divided into four groups (Table 1). Pigs of group 1 were untreated controls in which the skin allografts were allowed to reject naturally Pigs of group 2 received 3 0 ml /kg body weight of normal horse serum by intravenous injection daily, commencing on the day of skin grafting Pigs of groups 3 and 4 received 0 75 ml or 1 5 ml /kg body weight of horse anti-pig, anti-leucocyte serum daily by intravenous injection, commencing on the day of skin grafting. In all animals of groups 2, 3 and 4, administration of serum was continued until graft rejection was judged to be complete.

All skin grafts were examined, without previous knowledge of the origin of a particular graft, at 2 day intervals, starting on day 5 after skin grafting. Skin graft rejection was considered to have commenced on the first day that a graft was palpably thickened It proved difficult to assess the time of complete rejection on account of the thickness of pig skin

The times in days to the commencement of skin allograft rejection are shown in Table 1 It may be seen that normal horse serum, group 2, or the lower dose of horse anti-pig leucocyte serum, group 3, had no influence on the time of skin allograft rejection In a dose of 1 5 ml /kg body weight/day, however, the anti-leucocyte serum produced a striking delay in the commencement of skin allograft rejection

Necropsies were performed on all the pigs between the twenty-first and twenty-eighth days. No differences were observed with the naked eye or histologically between the lymph nodes of the groups given anti-leucocyte serum and the control groups All contained a normal amount of lymphoid tissue with normal germinal centres The lymph nodes which drained the graft areas were histologically similar to the other lymph nodes The spleens were also normal, and no abnormalities were seen in the kidneys by conventional staining and light microscopy.

The results indicate that it is possible to obtain a marked prolongation of skin allograft survival without serious toxicity It would be interesting to determine whether a still greater delay in skin graft rejection could be produced by larger daily doses of anti-leucocyte serum, or by a single massive injection of the anti-serum on the day of skin grafting

Cross-reaction of Anti-lymphocyte Serum with Haemopoietic Stem Cells

THE risk of provoking a fatal "secondary disease syndrome" has been an obstacle to the use of bone marrow transplantation for restoring haemopoiesis in radiation- or drug-induced aplasia This syndrome results from a graft versus host attack by immunologically competent cells derived from the grafted marrow Various methods have been tried for differentially eliminating immunologically competent cells from marrow preparations[1-3], but these have not been sufficiently effective to be of practical value The possibility that anti-lymphocyte serum (ALS) could be sufficiently specific to achieve this object prompted us to examine the extent to which haemopoietic stem cells cross-react with ALS Anticipating that some degree of cross-reaction would occur, we set out to obtain quantitative data for immunologically competent cells and for haemopoietic stem cells in terms of the proportions of cells inactivated by different dilutions of ALS

Haemopoietic stem cells were assayed by their capacity to restore haemopoiesis in recipients previously treated with supralethal doses of dimethyl myleran[4] The method was an adaptation of that described by Hodgson[5] Marrow cells were obtained from the femora and tibiae of rats of a highly inbred Marshall strain The cells were flushed out with ice-cold Ringer solution, and were dispersed in a glass homogenizer with a loosely fitting 'Teflon' plunger Recipients, which were either of the Marshall or of a (Marshall × August) F_1 hybrid strain, were injected intraperitoneally, on the day before marrow transfusion, with 5 8 mg/kg of dimethyl myleran dissolved in a mixture of 1 part of propylene glycol and 16 2 parts of physiological saline (Dimethyl myleran was first dissolved in propylene glycol at 70°–80° C to give a concentration of 10 mg/ml ; the dose of diluted material was then 1 ml /100 g) Seven days after marrow transfusion each recipient was injected intravenously with 0 2 μc of iron-59 (5–11 c /g, Radiochemical Centre, Amersham) as citrate and was bled 24 h later by cardiac puncture In calculating the proportion of the injected dose of iron-59 incorporated into circulating red cells, the blood volume was assumed to be 6 6 per cent of the body weight

Immunologically competent cells were assayed by their capacity to induce a graft versus host reaction Because of their greater abundance of cells in the spleen, this tissue was used as a source in preference to the bone marrow Suspensions of Marshall spleen cells in Ringer solution were prepared by finely mincing and straining the spleens through a 100μ mesh stainless steel sieve The increase in spleen weights of (Marshall × August) F_1 hybrids induced by Marshall spleen cells and measured 9 days after their intraperitoneal injection is, in this strain combination, linearly related to the number of cells injected, within the range used in these experiments

Rabbit anti-rat lymphocyte serum was prepared by the method of Levey and Medawar[6] Eight hundred million thymocytes, obtained from five Marshall thymuses, were injected intravenously into rabbits on two occasions 2 weeks apart The rabbits were bled 1 week after the second injection The sera were inactivated by heating at 56° C for 30 min, and were absorbed twice for 1 h with equal volumes of Marshall red cells (from which leucocytes had been largely removed by centrifugation), the first time at 37° C, the second at room temperature For comparison of effects on immunologically competent and on haemopoietic stem cells the same batch of ALS was always used in any one experiment

Spleen or bone marrow cells were incubated with ALS for 45 min at 37° C All dilutions of ALS and of cells were made with Ringer solution Spleen suspensions contained 100×10^6 cells/ml , marrow suspensions contained 13×10^6 cells/ml for Marshall or 20×10^6 cells/ml for hybrid recipients respectively Spleen cells (2 ml) or marrow cells (1 ml) were injected All rats in these experiments were males, weighing 120–150 g

A preliminary experiment was carried out to determine the range of ALS titres for which inactivation of immunologically competent and of haemopoietic stem cells could be demonstrated Marshall bone marrow and spleen cells were incubated with serial 1 2 dilutions of ALS and were then injected into Marshall and F_1 hybrid recipients, respectively An almost parallel inactivation pattern was obtained for these two classes of cells Dilutions of ALS up to 1 8 gave virtually complete inactivation in both cases The degree of inactivation then appeared to diminish with increasing dilutions of ALS, to approximately 50 per cent, at dilutions of 1 . 64 to 1 128, as compared with cells incubated with Ringer solution alone

On the basis of these results a more critical comparison was made of the extent to which the respective cell types were inactivated by ALS at two selected dilutions, namely, 1 10 and 1 100 The repopulating ability of ALS-treated Marshall haemopoietic stem cells was assayed in F_1 hybrid as well as in Marshall recipients, in order to test for any effect on transplantability into the hybrid strains of cells treated with antiserum prepared against the Marshall strain There were thus three test systems (*a*) Marshall spleen cells assayed by splenomegaly induced in F_1 hybrids ; (*b*) Marshall marrow cells assayed by repopulating ability in Marshall recipients, and (*c*) Marshall marrow cells assayed by repopulating ability in F_1 hybrids Each test system consisted of six groups, containing six rats in a group The first two groups of rats received cells treated with the two dilutions, 1 10 and 1 100 respectively, of ALS A third group received cells treated with normal rabbit serum at a dilution of 1 10 The remaining three groups received either the standard number of cells or half this number, in either case without previous serum treatment, or no cells at all The results are listed in Table 1

Table 1 INACTIVATION OF IMMUNOLOGICALLY COMPETENT AND HAEMOPOIETIC STEM CELLS OF MARSHALL RATS BY RABBIT ANTI-RAT LYMPHOCYTIC SERUM

Rabbit serum	Cell system tested: Immunologically competent cells (spleen weight of F_1 hybrid, mg)	Haemopoietic stem cells (% of iron-59 administered on day 7 incorporated into red cells in 24 h)	
		in Marshalls	in F_1 hybrids
Anti-lymphocytic serum 1/10	610 (39) ‡	12 2 (5 1)	14 3 (1 3)
Anti-lymphocytic serum 1/100	786 (43)	20 3 (0 7)	20 0 (2 0)
Normal rabbit serum 1/10	1,012 (56)	29 5 (4 2)	21 8 (6 0)
None (*a*) Full dose of spleen* or marrow† cells	923 (59)	25 3 (3 6)	29 4 (5 9)
(*b*) Half dose of spleen or marrow cells	784 (49)	23 3 (5 6)	21 0 (2 5)
(*c*) No spleen or marrow cells	600 (11)	8 2 (2 3)	14 2 (1 3)

* 200×10^6 Marshall spleen cells given intraperitoneally to (Marshall × August) F_1 hybrids 9 days before killing

† Marshall rats given 13×10^6, F_1 hybrids 20×10^6, Marshall marrow cells intravenously 24 h after treatment with 5 8 mg/kg of dimethyl myleran

‡ Mean values for six rats, standard errors in parentheses

ALS in a dilution of 1 10 completely inactivated both the immunologically competent cells and the haemopoietic stem cells Both these cell types were reduced in effectiveness by ALS in a dilution of 1 100 to levels corresponding almost exactly (although confidence limits were wide) with those observed with half the standard number of untreated cells Normal rabbit serum in a dilution of 1 10 was without effect (The apparent reduction in the repopulating ability of stem cells in F_1 hybrids after treatment with normal serum was probably not real ($P > 0$ 1) In contrast to the normal rabbit serum used in the other two experimental systems, the batch used in this system had not been absorbed with rat red cells This may have contributed to this effect)

In these experiments no difference could be demonstrated in the effectiveness of ALS against splenic lymphoid cells and against bone marrow stem cells Several hypotheses can be advanced to explain the cross-reactivity of these two cell types The morphological identity of haemopoietic stem cells has never been established and it has been suggested that they may even be indistinguishable from marrow lymphocytes. This contention lends support to the monophyletic theory of the origin of lymphoid and erythroid series[7,8] and if correct would also explain their antigenic similarity. An alternative explanation may be that thymocytes, as opposed to splenic lymph node or blood lymphocytes, were the source of antigen in the preparation of the ALS used in these experiments. Thymocytes are derived from the bone marrow[9], so the similarity in antigenic composition with haemopoietic stem cells may result from a common origin. It is possible that a greater degree of antigenic disparity may exist between marrow stem cells and true lymphoid cells which might be brought to light if the latter cells were used for immunization. Recent work has shown that thymocytes possess some antigens not present in other lymphoid cells[10].

These experiments give no explanation of the mechanism of inactivation by ALS of either of these two types of cell. Our (unpublished) observation, that the addition of guinea-pig complement does not enhance the inactivation of either cell type *in vitro* by dilutions of ALS down to 1:128, supports the view that the action of ALS is predominantly cytotoxic. If a process operated *in vivo* that did not depend on the action of the recipient's own complement, a synergistic effect could be expected between this process and the complement present during *in vitro* incubation. It is possible that coating the cell surface with antibody interferes with the homing property of haemopoietic stem cells to the bone marrow and of immunocompetent cells to the sites in lymphoid tissues in which they initiate a graft versus host reaction.

There is an unexplained discrepancy. On the one hand, ALS has an immediate effect on immunocompetent cells *in vitro*, as reported in these studies and by Brent *et al.*[11], who used mortality in mice injected neonatally with allogeneic lymph node cells as their assay system. On the other hand, a delay of 3–6 days has been reported to occur between the injection of ALS *in vivo* and maximal suppression of immune function, as demonstrated by the capacity of the animal to reject allogeneic skin grafts[12], and of lymph node cells to produce haemolysins and agglutinins to foreign red cells[13], and to induce fatal graft versus host disease[11]. Although injected ALS produces an immediate fall in number of circulating lymphocytes[14], it is apparently prevented from reaching extravascular lymphoid tissues for several days.

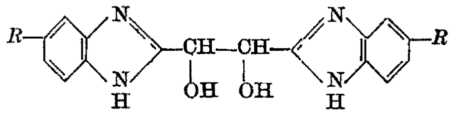
PATHOLOGY

Inhibitory Effect of 1,2-*bis*(2-Benzimidazolyl) 1,2-ethanediol Derivatives on Poliovirus

THE inhibitory properties of 2-(α-hydroxybenzyl) benzimidazole (HBB) on the replication of poliovirus have been fully demonstrated[1,2]. O'Sullivan *et al.*[3] also reported that 1,2-*bis*(2-benzimidazolyl) 1,2-ethanediol (I) has a selective inhibitory action on the multiplication of poliovirus. On the basis of these findings, we have synthesized, 1,2-*bis*(2-benzimidazolyl) 1,2-ethanediol derivatives and tested them for their anti-poliovirus effect.



$R = H$ (I), $R = CH_3$ (II), $R = Cl$ (III), $R = OCH_3$ (IV)

1,2-*bis*(2-Benzimidazolyl) 1,2-ethanediol derivatives were prepared by the following procedures. *o*-Phenylenediamine or 4-methyl, 4-chloro, and 0.04 molar 4-methoxy *o*-phenylenediamine were dissolved in 50 ml. of 4 normal hydrochloric acid in a 300 ml round flask. To this solution was added 0.02 molar tartaric acid and the mixture was refluxed gently on a sand-bath for 2–3 h. The reaction mixture was cooled externally with cold water and neutralized with 20–30 per cent sodium carbonate solution while stirring. The solution was kept in an ice-box overnight to complete crystallization. The crystals were collected by filtration and then recrystallized three times from dil. ethanol. The properties and yields of the compounds are given in Table 1.

The anti-poliovirus activity of these compounds was tested by using a poliovirus type 1 (Mahoney strain) and HeLa S_3 cells in the following way. A suspension of HeLa S_3 cells (4 ml containing 2×10^5 cells/ml.) in YLE growth medium (1.0 g of yeast extract and 5.0 g of lactalbumin hydrolysate in 1,000 ml of Earle's balanced salt solution, with 100 U of streptomycin and 500 U of penicillin supplemented with 10 per cent calf serum) was put into a plaque bottle, and incubated at 37° C for 4 days. After the monolayer cell sheet has been established, the growth medium was removed and, immediately after washing with phosphate buffered saline (PBS, *p*H 7.2), 0.05 ml of different dilutions (10^{-3}–10^{-6} molar) of each tested compound and 0.45 ml of the poliovirus dilution (30–40 PFU/bottle) were added. After incubation for 1 h at 37° C, the culture fluid was removed, and the cells were washed three times with PBS. Then 4.5 ml of agar overlay medium and 0.5 ml of the diluted compound were added in turn to the bottle. The agar overlay medium consisted of equal volumes of 1.8 per cent Bacto-Difco agar and twice concentrated YLE medium supplemented with 8 per cent calf serum and 0.0025 per cent (final concentration) neutral red. After incubation for 4 days at 37° C plaques were counted. For untreated control groups, the same amount of PBS was used instead of one of the compounds being tested. The results shown in Table 2 indicate that 1,2-*bis*(2-benzimidazolyl) 1,2-ethanediol derivatives clearly inhibit the replication of poliovirus. Compound IV showed complete inhibition.

The anti-poliovirus activity of compound IV was also examined by the $TCID_{50}$ estimating dilution method, as shown in Table 3, which indicates that the minimum inhibitory concentration of this compound was about 2×10^{-7} molar. This effect is about 1,000 times greater than that of HBB or guanidine[4]. The possibility that compound IV affected the cells themselves in any way can be excluded. Compound IV showed no toxicity in a

concentration of 10^{-4} molar in 7 days, but in a concentration of 10^{-3} molar cells were degenerated or separated from tissue culture tubes Recent results (reported at the Fifteenth General Meeting of the Society of Japanese Virologists in October 1967 at Chiba) show that (*a*) the incorporation of 2-^{14}C-uridine and ^{3}H-valine did not differ between cell cultures without compound IV and cultures treated with 10^{-4} molar compound IV, and (*b*) compound IV strongly reduced the yield of intracellular virus This compound can therefore be supposed to be non-toxic.

Table 3 ANTI-POLIOVIRUS ACTIVITY OF 1,2-BIS[5(OR 6)-METHOXY-2-BENZIMIDAZOLYL] 1,2-ETHANEDIOL

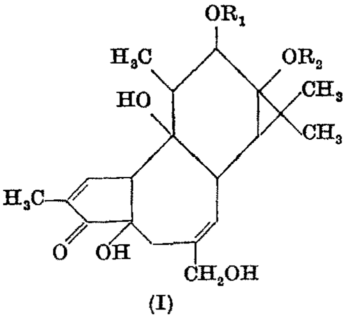
Response of an Active Component of Croton Oil to Short-term Tests of Carcinogenicity

THE cocarcinogenic properties of croton oil have been known for a long time[1], and there have been many attempts to identify its active components[2,3]

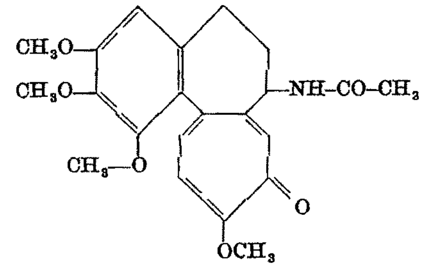
Hecker *et al* [3-8] succeeded in isolating a set of phorbol esters from croton oil According to these authors phorbol is a tetracyclic diterpene $C_{20}H_{28}O_6$ Its structural formula is now known to correspond to the formula (I) shown[8], where $R_1 = R_2 = H$ Hecker's experiments showed that these esters, apart from being promoters of cancer, also have a mild but definite tumour initiating effect[9].

Among the isolated esters of phorbol, Hecker's substance A_1 (ref 5) proved to be the most powerful This product has the same melting point (72° C) as "substance *C*-3" of Arroyo and Holcomb[10] and the same mass spectrum as "substance *C*" of Van Duuren and Orris[2] Substance A_1 is supposed to be *c*-acetyl-*b*-myristoyl-phorbol (that is, 13-O-acetyl-phorbol-12-myristate) $C_{36}H_{56}O_8$, corresponding to formula (I), where R_1 is a myristoyle, and R_2 an acetyl residue[5,8]

We have investigated the response of Hecker's substance A_1 to the short-term tests of carcinogenicity Two tests—the sebaceous gland suppression test and the epidermal hyperplasia test—were made by our usual



(I)



(II)

Table 1 RESULTS OF THE SEBACEOUS GLAND SUPPRESSION AND HYPERPLASIA TESTS

	Controls	Dose 1 10,000	Dose 1 1,000*
Mean of No of sebaceous glands ± 2 standard errors	19 1±1 2	4 4±1 3	4 9±1·9
Mean epidermal thickness ± 2 standard errors	19 6±2 2	63 3±3 6	71 6±9 5

* In some cases ulceration was present

routine[11]. Mice of the *IC* strain, 49 days old, were used in the tests The substance was dissolved in acetone and was tested in two dilutions 1 1,000 and 1 10,000 There was a strongly positive reaction in both cases (Table 1)

The phorbol ester which we have studied is one of the substances which, as well as being cancer initiators or promoters, give positive sebaceous gland suppression and hyperplasia tests These findings emphasize the correlation between carcinogenicity and positive response to short-term tests This relationship is particularly interesting because so far it has usually been described within the polynuclear hydrocarbons[12,13]; our results enlarge the field of application of such tests

It is also interesting that there is, according to Sivak, an analogy of structure and configuration between phorbol and colchicine (formula (II)) This latter substance gives a positive short-term test[12,13] without any known property of initiating or promoting cancer

We thank Professor Erich Hecker, Director of the Biochemical Institute, Deutsches Krebsforschungszentrum, Heidelberg, for substance A_1 used in these experiments

Infectious Mononucleosis: Continuous Suspension Culture of Peripheral Blood Leucocytes

THE atypical lymphocyte in patients with infectious mononucleosis, like the leukaemic lymphocyte, is capable of spontaneous *in vivo* proliferation This is shown by dividing and binucleate forms in circulation[1], increased concentrations of cellular enzymes associated with nucleic acid synthesis[2], markedly increased premitotic activity with incorporation of tritiated nucleoside precursors[3] and early *in vitro* division of some of these labelled cells[4] Spontaneous lymphoblastoid transformation of fibroblastic elements derived from bone marrow of patients with infectious mononucleosis has been described[5] with long term culture of these cells in suspension[6] Despite the increased proliferative potential of peripheral atypical lymphocytes in this disease, little is known about the progeny of these cells No established culture of lymphoid cells derived from peripheral blood of patients with infectious mononucleosis has previously been reported

Our attempts to establish long term cultures of peripheral blood leucocytes from patients with infectious mononucleosis, evaluated at the National Institutes of Health and diagnosed with criteria suggested by Hoagland[7], include thirty-one samples taken from fifteen individuals at various stages of the disease Twenty-six samples from thirteen patients with clinical diseases without infectious mononucleosis or known malignancy and fourteen samples from ten individuals without clinical illness were studied collaterally (Table 1).

Table 1 ATTEMPTS TO ESTABLISH LONG TERM SUSPENSION CULTURE OF PERIPHERAL BLOOD LEUCOCYTES

Group	No of individuals	No of specimens	Lymphocytes/10 ml of medium
No clinical illness	10	14	$3 0\times10^{6}$–$2 0\times10^{7}$
Clinical disease other than infectious mononucleosis or malignancy	13	26	$3 4\times10^{6}$–$2 0\times10^{7}$
Infectious mononucleosis	15	31	$3 0\times10^{6}$–$2 5\times10^{7}$ (1 specimen at $5 6\times10^{7}$)

Leucocyte cultures were prepared by gravity sedimentation of heparinized peripheral blood at 37° C for 1–2 h and centrifugation of the plasma supernatant rich in leucocytes at 250*g* in the International *PR*-2 at 20° C for 30 min A sample ($3 0\times10^{6}$ to $5 0\times10^{7}$) of lymphocytes (determined by direct differential count on a haemocytometer) was cultured at 37° C in 2 ounce screw top prescription bottles containing 10 ml of RPMI 1640 medium[8], supplemented with 20 per cent heat-inactivated foetal calf serum, penicillin, streptomycin and *l*-glutamine Between 30 per cent and 50 per cent of the supernatant culture fluid was removed and replenished with fresh medium after gravity sedimentation of cells in each culture twice a week for the first 2 weeks and then weekly until a culture was terminated No effort was made to maintain the original cell concentration Cultures were observed daily with a Zeiss inverted microscope for signs of spontaneous proliferation and were discarded when intact lymphocytes were no longer visible

Eight specimens from peripheral blood of five patients with infectious mononucleosis have proliferated in long term suspension culture (Table 2) Initial signs of proliferation were evident after 21–44 days of culture with progressive *p*H (acidic) changes in the medium, clumping of cells in suspension and increase in cell number At present these established lines do not require feeder layers and have no fibroblastic component when grown in medium containing foetal calf serum Cells adherent to glass were noted, however, in the first few weeks of culture in seven of the eight lines established and either fibroblastic or epithelioid elements or both appear in all cultures grown in medium lacking foetal calf serum The cells in suspension culture have been maintained for at least 3–7 months and show no loss of vitality or signs of termination No long term suspension cultures were obtained from individuals without clinical illness or individuals with diseases other than infectious mononucleosis with the culture techniques used

Table 2 SPECIMENS OF PERIPHERAL BLOOD LEUCOCYTES FROM PATIENTS WITH INFECTIOUS MONONUCLEOSIS PROLIFERATING IN LONG TERM SUSPENSION CULTURE

Cell line	Total lymphocytes cultured/10 ml of medium	Signs of proliferation evident (days in culture)	Patient's highest guinea-pig kidney adsorbed serum heterophil titre
J P (*H*)	$1 0\times10^{7}$	36	1 896
J P (*J*)	$1 0\times10^{7}$	21	
W R (*D*)	$6 0\times10^{6}$	44	1 1,792
W R (*F*)	$1 0\times10^{7}$	41	
E C (*B*)	$5 6\times10^{7}$	35	1 7,168
L M (*B*)	$2 4\times10^{7}$	24	1 112
L M (*D*)	$1 4\times10^{7}$	40	
M K (*B*)	$2 4\times10^{7}$	34	1 448

The established lines grow essentially as free-floating pleomorphic forms with a tendency to clump despite agitation which easily reseparates them into individual cells. Giemsa staining reveals wide morphological heterogeneity with a fundamental lymphoid character with densely stained nucleus, readily visualized nucleoli, vacuoles and variable amounts of basophilic to faint staining cytoplasm. There is considerable variation in cell size and shape and quantity of uropodia. The cells look quite immature, resembling lymphoblasts and lymphocytes stimulated with phytomitogen (phytohaemagglutinin/pokeweed mitogen)[9,10]. Cells reminiscent of plasmacytoid Downey cells[11] and bizarre nuclear forms are frequently seen. Ultrastructure analysis shows a spectrum of lymphoid cells varying from small cells with close morphological similarity to atypical lymphocytes obtained from peripheral blood of patients with infectious mononucleosis, to large multinucleate forms. Varying amounts of rough surfaced endoplasmic reticulum with occasional dilated cisternae and scattered free polyribosome complexes are present.

Chromosomal analysis shows a predominantly diploid mode for all lines with a pseudodiploid population accounting for 4 per cent of metaphase plates examined in one of the lines. Doubling times range from 48–80 h in the standard culture medium. Cells actively ingesting cellular and nuclear material are present in all cultures. Following incubation with sterile polystyrene particles (0.8 mm, Dow Chemical Co.) or heat-killed *Staphylococcus albus*, 15–30 per cent of the cells showed evidence of phagocytosis. Ingestion of *Staphylococcus albus* was not associated with release of endogenous pyrogen[12]. Histochemical analysis revealed varying quantities of lysosomal enzymes but complete absence of peroxidase and leucocyte alkaline phosphatase. Most cells contain material which stains positively by the periodic acid–Schiff reaction. No morphological differences could be discerned for phagocytic and non-phagocytic cells before incubation with foreign particles.

The ability of these lymphoid cells to synthesize immunoglobulins was assayed by the radioimmunoelectrophoretic technique[13] in 18 h culture containing various cell concentrations in 2 ml of medium. Dried immunoelectrophoresis plates were exposed to standard X-ray film for 5–14 days before developing. Nascent synthesis of IgM, IgA and IgG, detectable at cell concentrations as low as 5.0×10^5/ml, was demonstrated with mono-specific anti-human immunoglobulin sera. Antibody specificity of these newly synthesized immunoglobulins is under investigation.

Interferon-like activity has been demonstrated in the supernatants from these cell lines (unpublished results). This material is not sedimented by centrifugation at 105,000*g* for 90 min. It exhibits specificity for cells of human origin, is sensitive to trypsin and cannot significantly inhibit adenovirus replication. This activity is reduced by pretreatment with actinomycin *D* of the host cell. No bacteria, virus, fungus or mycoplasma have been isolated from these lines.

Multiple continuous, long-term suspension cultures of lymphoid cells derived from peripheral blood of patients with lymphoblastic leukaemia[14], myelogenous leukaemia[15], Burkitt's lymphoma[16], Hodgkin's lymphoma, lymphosarcoma and multiple myeloma[17] have been described. Lethally irradiated Burkitt's lymphoma cells with herpes-type virus particles have been reported to induce long term culture of normal leucocytes with acquisition by these cells of herpes-type viral antigen and *C*-group chromosomal markers[18]. With special techniques established cultures of lymphoid cells from peripheral blood of "normal" individuals have been obtained as well[8]. Many of these normal lines, however, harbour herpes-type virus particles, and long-term culture may well be a result of latently infected cells circulating in individuals without clinical illness. With the techniques used, this background potential was not encountered in our control samples. Collateral specimens from patients with infectious mononucleosis have proliferated in long-term culture.

Infectious mononucleosis may simulate acute leukaemia and is thought by some observers to represent an atypical form with a self-limiting course[19]. Demonstration of the increased *in vitro* proliferation of peripheral blood leucocytes from patients with infectious mononucleosis similar to neoplastic cells in leukaemia and lymphoma supports the thesis of common cellular potential in these lymphoproliferative states and offers a tool for investigation of this relationship.

Endogenous pyrogen was assayed by Dr Richard Root. Histochemical analysis was performed by Dr Harvey Gralnick. We thank Mrs Patricia Baker, Mrs Turid Knutsen, Miss Margaret Huber, Holly Smith and Edward Harvey for technical assistance.

Seizures in Experimental Porphyria

WE report work which represents the first experimental model for neurological effects observed in acute intermittent porphyria (AIP), a genetically determined disorder, clinically characterized by gastrointestinal, neurological and psychotic signs. Increased urinary excretion of the porphyrin precursors delta-aminolaevulinic acid (ALA) and porphobilinogen (PBG) is found in overt as well as in most of the latent asymptomatic cases. Severe, often fatal, attacks may be precipitated or aggravated by certain drugs, especially barbiturates. The mechanisms responsible for the clinical signs in AIP, all of which seem to be on a neurogenic basis, are totally unknown[1,2], the risk involved by the use of drugs precludes clinical studies on the possible factors involved until more information can be derived from experimental models. Chemical manifestations, similar to those of the human disorder—

that is, increased synthesis and excretion of porphyrins and their precursors—can be produced in laboratory animals by the use of certain drugs. No clear-cut neurological abnormalities, however, have been described in experimental porphyria[2].

We have found that rats, made porphyric by allylisopropylacetamide (AIA), are very susceptible to induced convulsions. The induction of seizures in these animals is a tool for studies of abnormalities in neurological functions associated with disturbances in porphyrin metabolism. These in turn might shed some light on the factors involved in the deranged functions of the nervous system in human porphyria.

Female Sprague–Dawley rats, weighing 150–160 g, were injected subcutaneously with AIA solution in 0·15 molar sodium chloride, at a dose of 400 mg/kg, between eight and ten daily injections were given. Excessive urinary excretion of ALA and PBG was noted by established methods[3,4]. Twenty-four hours after the last injection of AIA, groups of these rats, as well as control animals, were injected intraperitoneally with solutions—made in 0·15 molar sodium chloride—of the following compounds: (*a*) isonicotinoylhydrazide (INH), (*b*) 4-methoxymethylpyridoxol hydrochloric acid, adjusted to *p*H 7, (*c*) 4-deoxypyridoxol hydrochloric acid, adjusted to *p*H 7. Some animals were injected intraperitoneally with pyridoxol hydrochloric acid solution in 0·15 molar sodium chloride, adjusted to *p*H 7, 15 min before injections of these compounds. The rats were observed for 4 h after the injections and checked again 24 h later.

A dose of 0·75 mmoles/kg of INH induced generalized clonic-tonic convulsions in 60 per cent of the porphyric rats whereas none of the control animals convulsed; at a dose of 1·12 mmoles/kg, 90 per cent of the porphyric rats convulsed as compared with 20 per cent of the control group. At this and at a higher dose level very severe convulsions were noted in the porphyric rats as compared with mild convulsions seen in the control animals. In general, the convulsions occurred at 30–60 min after the injection. None of the animals died (Fig. 1). Pyridoxol at doses of 0·5–2 mmoles/kg did not modify the pattern of convulsions induced by INH at a dose of 1·12 mmoles/kg.

A marked difference between control and AIA treated rats was found after injection of 4-methoxymethylpyridoxol (Fig. 2). Seventy per cent of the porphyric rats convulsed after injection of 0·25 mmoles/kg. All porphyric rats convulsed when given 0·75 mmoles/kg, whereas none of the control rats was affected by this dose. At a dose of 1 mmole/kg, 20 per cent of normal rats showed generalized but mild convulsions occurring at 30–60 min after the injection, as compared with very severe repeated tonic-clonic convulsions in all porphyric animals at 10–30 min after the injection. None of the animals died. Some protection was noted upon injection of pyridoxol; 2 mmoles/kg reduced the convulsions induced by 0·75 mmole/kg 4-methoxymethylpyridoxol from 100 per cent to 40 per cent. The severity of the convulsions induced by this and by higher doses of 4-methoxymethylpyridoxol was decreased in animals injected with pyridoxol, and there was a delay in the appearance of seizures from less than 30 min to about 1 h. No complete protection, however, was achieved in any of the groups by varying the doses of pyridoxol.

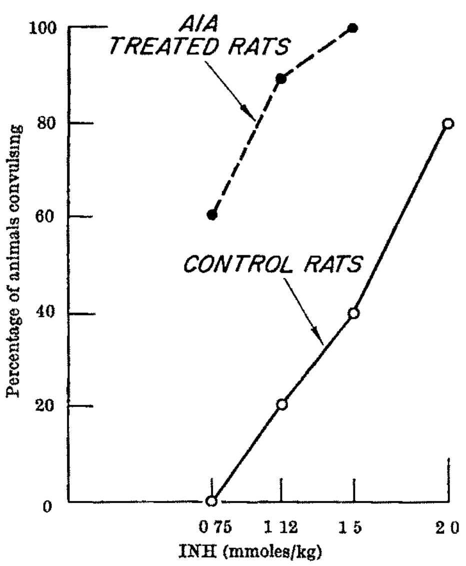

Fig. 1. Convulsions induced by INH in rats treated with AIA and in control rats. Ten to fifteen animals were used for each point.

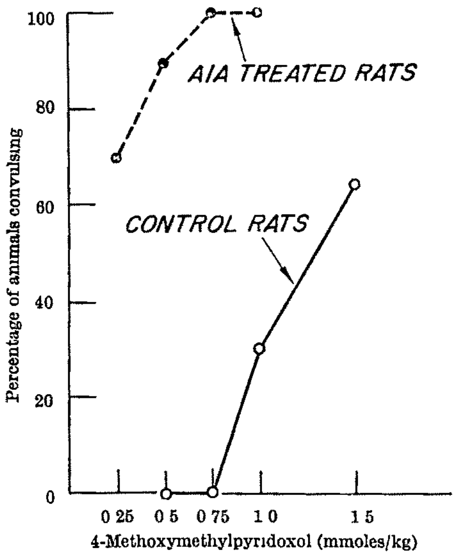

Fig. 2. Convulsions induced by 4-methoxymethylpyridoxol in rats treated with AIA and in control rats. Nine to twelve animals were used for each point.

No difference was found between rats treated with AIA and control rats after injection of 4-deoxypyridoxol (Table 1). The dose-response curve was found to be very steep for both groups. One control and one rat treated with AIA died and several other AIA treated rats showed only mild convulsions at a dose of 3·0 mmoles/kg; most animals in both groups died within 60 min after injection of 3·5 mmoles/kg of 4-deoxypyridoxol.

Table 1. EFFECT OF 4-DEOXYPYRIDOXOL ON CONTROL RATS AND ON RATS TREATED WITH AIA

Dose mmoles/kg	Rats treated with AIA		Control rats	
	Convulsions	Mortality	Convulsions	Mortality
3·0	4/12	1/12	1/8	1/8
3·5	8/10	7/10	9/10	8/10

The mechanisms of action of carbonyl reagents and of pyridoxol analogues are not clearly understood. The convulsions induced by these reagents have been attributed to interference with the metabolic pathways of the nervous system, in which pyridoxal-5-phosphate is an essential cofactor: for example, the γ-aminobutyric acid pathway. It has been assumed that INH forms hydrazones with pyridoxal and pyridoxal-5-phosphate, thereby inhibiting pyridoxal kinase and some enzyme reactions involving pyridoxal-5-phosphate. Pyridoxol analogues, such as 4-deoxypyridoxol, may, after their phosphorylation, serve as competitive inhibitors of several pyridoxal-5-phosphate dependent enzymes, but the exact modes and sites of action, as well as the possible active derivatives of these compounds, are not known[5-7]. An increased sensitivity to INH is associated with decreased brain content of pyridoxal-5-phosphate[8].

ALA synthesis, for which pyridoxal-5-phosphate serves as a cofactor, is markedly increased in the liver of porphyric animals and in the liver of patients suffering from AIP[9-12]. An increase in the liver pool of this cofactor could lead to a relative deficiency in other organs, such as the nervous system. Indeed, many of the clinical and pathological signs of porphyria are similar to those in other syndromes where pyridoxine deficiency has been postulated[13,14]. A simple deficiency of pyridoxine, however, does not explain the results reported here. Whereas the rats treated with AIA showed a marked sensitivity to 4-methoxymethylpyridoxol, no difference from normal was noted after 4-deoxypyridoxol injection. The different action of the two pyridoxol analogues and the lack of a definite protection by pyridoxol against convulsions induced by 4-methoxymethylpyridoxol and INH point to a more specific mode of action than is implied by a general deficiency. No deterioration in the clinical state of a patient suffering from AIP was noted after treatment with 4-deoxypyridoxol[15]. Treatment of patients with pyridoxol during acute attacks of porphyria either did not change the clinical course or it coincided with a worsening of the clinical state (unpublished observations). One cannot therefore imply a simple deficiency of the cofactor in any of these cases. In other situations, where abnormalities in pyridoxine metabolism have been assumed to occur, no simple deficiency is sufficient to explain the observed signs; while some of the neurological abnormalities, observed in patients who receive INH, can be prevented by therapy with pyridoxol, increase in the severity of symptoms was observed in some patients being treated with INH as well as in some patients with a variety of nervous system disorders[16,17].

Our experiments have shown that there are neurological disturbances in porphyric rats which are related to some aspects of pyridoxine action. It seems most probable that the initial site of action of the antagonists is a pyridoxal dependent enzyme. Obvious possibilities are glutamic acid decarboxylase and γ-aminobutyric acid transaminase. Glutamic acid and γ-aminobutyric acid have been implicated as transmitter substances in nervous tissue. Other possible sites include metabolic pathways of catecholamines, acetylcholine and of structural proteins in reactive membranes[5-7]. We have found that ALA rapidly forms imines with pyridoxal and pyridoxal-5-phosphate (our unpublished results). The kinetic and thermodynamic properties of the products are compatible with a role as competitive inhibitors *in vivo* at locations far from their point of generation. Such compounds, for example, imines and their derivatives, can have sufficient structural and steric specificity to serve as inhibitors to some of the key enzymes. Such an inhibition could change functional activity of the nervous tissue and lower the threshold for convulsions.

Further studies on this experimental model might help in clarifying the influence of disturbances in porphyrin metabolism on metabolic pathways of nervous tissue.

We thank Hoffmann-La Roche for the supply of allylisopropylacetamide, and Merck, Sharp and Dohme for the supply of 4-methoxymethylpyridoxol. This investigation was supported by grants from the US National Institutes of Health.

CYTOLOGY

Heterochromatic Segments in *Vicia* revealed by Treatment with HCl–Acetic Acid

YAMASAKI[1] reported that *H* segments became visible in the mitotic metaphase chromosomes of *Cypripedium debile* following treatment with a 1 : 9 mixture of 1 normal HCl and 45 per cent acetic acid or acetic orcein for 15 min at 60° C. Sharma and Roy[2] and Sen[3], using the orcein mixture at 90° C, claimed that the treatment caused chromosome breakage at non-specific sites within a minute. The present experiments on *Vicia faba* ("Nagasaya Soramame") studied the effects of these mixtures and the separate effects of 1 normal HCl and 45 per cent acetic acid. Treatments lasting 1–5 or 10 min were given at 60° C and 90° C. Pretreatment with colchicine was necessary to facilitate observation, but fixation in acetic alcohol before treatment was not helpful.

At 90° C, treatment of up to 2 min with a 1 : 9 mixture of 1 normal HCl and 2 per cent orcein in 45 per cent acetic acid had no effect while treatment for more than 4 min gave reduced stainability. *H* segments were invariably revealed, especially in the *M* chromosomes (Fig. 1) after 3–4 min treatments, and no indications of breakage were observed in any of the experiments.

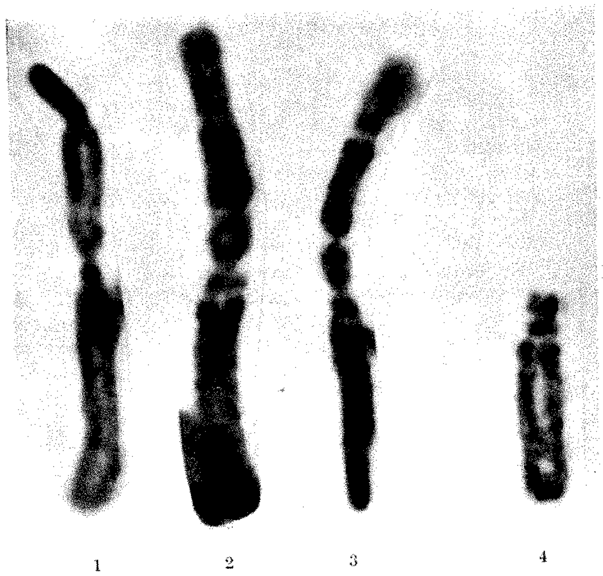

Fig. 1. 1, 2 and 3: the *M* chromosomes showing heterochromatic segments are arranged according to the order in which the *H* segments appear. 4 is an *S* chromosome showing a heterochromatic segment. (Same magnification.)

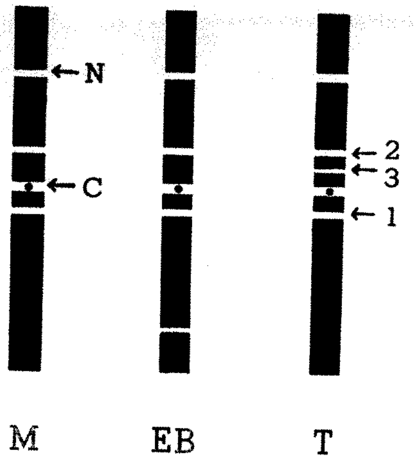

Fig. 2. The positions of the centromere (C), nucleolar organizer (N) and heterochromatic segments (other gaps) as described by McLeish[4] (M), Evans and Bigger[5] (EB) and myself (T). 1, 2 and 3 indicate the sequence in which the *H* segments become evident.

Treatment with HCl–acetic acid followed by Feulgen staining was preferable to treatment with HCl–orcein and the best results were obtained after 3 min treatment at 90° C.

The *H* segments described by McLeish[4] following cold treatment in *Vicia* are even more obvious after treatment with HCl–acetic acid. But the additional *H* segment described by Evans and Bigger[5] is not evident. HCl–acetic acid, however, reveals further segments which have not been described following cold treatment (Fig. 2).

I thank Professor T. Miduno and Dr N. Yamasaki for criticism and help.

Chromosome Aberrations during Normal Epithelial Proliferation

EARLIER investigations[1] have shown that a spectacular cellular proliferation occurs in the epithelium of the mouse Müllerian vaginal anlage and in the uterine cervix during approximately the first week after birth. This proliferation is paralleled by a cellular degeneration[2]. It has been suggested that the latter phenomenon is caused, at least in part, by a degeneration of cells with abnormal mitoses which appear during the proliferation[3].

Because abnormal mitoses appear during this proliferation, we thought that it would be interesting to investigate also whether some cells have a chromosome number which is different from the normal diploid number in a mouse (40). This communication presents evidence for the existence of such cells.

Young albino mice from a closed stock were used. The animals were injected with colchicine (1 μg in 0·05 ml. of Tyrode solution) on the day of birth and were killed 6 h later. The anterior part of the vaginal anlage and the uterine cervix were dissected out. The preparations were put into a 3 per cent solution of trypsin (Difco, 1 : 250) in Tyrode solution free from calcium and magnesium at 37° C for 5 min. While still in the trypsin solution but now at room temperature, the epithelium was dissected free from mesenchyme with fine glass needles. The epithelium was then transferred to a hypotonic solution (Parker 199 and distilled water, 1 : 5) for 90 min. The preparations were fixed in a solution of acetic acid, normal hydrochloric acid and distilled water (6 : 1 : 3); they were stained in acetic orcein, and squashed. The cover glass was framed with Kroenig cement.

Because the squash technique can introduce errors when chromosomes are lost from a cell, we did not analyse any cells with less than forty chromosomes. The metaphases studied were all well circumscribed and the chromosomes in each metaphase were all contracted to the same extent.

The chromosomes of 469 cells, hypodiploid cells not being included, were analysed from about twenty-five newborn mice. Among these 469 cells, forty-eight had more than forty chromosomes. Twenty-seven cells (5·4 per cent) had 41–49 chromosomes, ten cells (2·1 per cent) had 50–69 chromosomes, and eleven cells (2·3 per cent) had 70–80 chromosomes. A cell with forty-two chromosomes is shown in Fig. 1.

Four metacentric chromosomes were seen. One cell had forty acrocentric chromosomes and one metacentric chromosome. The remaining three metacentrics (Fig. 2) were found in groups of chromosomes which could not definitely be considered to belong to a single cell.

Aneuploidy and structural differences in chromosomes are common phenomena in cancer and precancerous conditions[4–7], in cells in tissue culture[8], in short term cultures of the human endometrium[9] and after cells have been exposed to X-rays[10]; opinions differ about their occurrence in regenerating liver[4,11]. Special types of chromosomal aberrations can be seen in patients with an abnormal sex chromosome set, Down's syndrome and similar conditions.

Chromosomal aberrations can be tolerated in a cell as long as the genome for replication is intact and as long as the cell is not exposed to special demands. When this occurs—for example, during the differentiation of the epithelium in the anterior part of the vaginal anlage and the uterine cervix—it seems unlikely that the unbalanced genome is compatible with cell life, for cells with deviating genotypes are exposed to a strong negative selection[12]. We think that cells with abnormal genotypes occur by chance during proliferation. When the epithelium differentiates later, these cells die and could contribute to the degeneration in the same region[13].

A tetraploid chromosome number is usually found in some tissues such as bone marrow, liver, transitional

epithelium and in glia cells in the cerebellum[11,14-16]. Müllerian epithelium from the anterior part of the vaginal anlage and uterine cervix in neonatal mice can also be included in this group.

GENETICS

Production of Foetal Haemoglobin in Marrow Cultures of Human Adults

IN the usual conditions of marrow culture, haemoglobin synthesis is maintained for only short periods. Kraus (ref. 1 and personal communication) reported on a long-term bone marrow culture method maintained at less than 37° C. In experimenting with this technique, we observed increased foetal ($\alpha_2\gamma_2$) haemoglobin synthesis in culturing adult marrows.

Marrow from adults was obtained during routine aspirations or from ribs obtained at cardiac surgery. Haematological diagnoses included various anaemias, leukaemia, suspected metastatic disease and Gaucher's disease. None of these patients had an elevated amount of Hb-F. Marrow suspensions (5×10^5–5×10^6 nucleated cells/mm^3, using 0·5 ml. of marrow in each culture) were drawn into 1 per cent sterile heparin, stored in the dark for less than 1 h at room temperature and placed in a 25 ml. vessel fitted with a ground glass top and containing 18 ml. of Tyrode solution, phenol red as *p*H indicator, 400 U of penicillin, 400 μg of streptomycin/ml. of media and 2·5 ml. of the patient's plasma or foetal calf serum. Incubation in the dark at 27° C lasted for various times between 1 and 20 days. ^{14}C-Leucine (5 μc./culture) or citrated iron-59 in 1·5 ml. of patient's serum or foetal calf serum (10 μc./culture) was added to label any haemoglobin synthesized during incubation. At the end of incubation, the contents of the culture were washed four times with isotonic saline. Cells were lysed with 2 ml. of distilled water and all cell debris was discarded after high-speed centrifugation. The haemoglobins of the resultant supernates were separated either by starch gel electrophoresis using TEB–borate buffer[2] or by starch grain electrophoresis using a buffer which separates Hb-A from Hb-F (15·5 g of H_3BO_3, 54·5 g of *tris* 7–9 and 2·9 g of ethylenediamine tetraacetic acid diluted with water to 2,000 ml. (*p*H 8·6). Borate buffer for the vessels (*p*H 8·5)—222·7 g of H_3BO_3 and 43·8 g of NaOH diluted with water to 24 l.—was suggested by Miss J. Anderson of the King County Blood Bank, Seattle. The alkali denaturation method of Betke[3] was also used to separate foetal haemoglobin.

Haemoglobin synthesized during incubation was estimated by measuring the amount of radioactivity incorporated into various haemoglobins separated by these methods. Non-radioactive carrier foetal haemoglobin was added to the radioactive haemolysates just before separation. When ^{14}C-leucine was used, liquid scintillation counting was carried out on the various haemoglobin fractions recovered from starch grain using Bray's counting solution[4] in a Packard 'Tri-Carb' liquid scintillation spectrometer. When iron-59 was used, the samples of haemoglobin were separated by both starch gel electrophoresis and starch grain electrophoresis. The radioactivity of the starch gel separations was measured in an auto-scaler after cutting the gel into a series of separate bands.

Marrows incubated in these conditions showed a reduced number of nucleated cells: 1×10^6/mm^3 of culture media on the first day and 3×10^4/mm^3 of culture media on the eleventh day of incubation. The amount of radioactivity incorporated into haemoglobin each day also decreased with prolonged incubation (Table 1).

Table 1. INCORPORATION OF ^{59}FE INTO HAEMOGLOBIN IN CULTURES INCUBATED FOR INCREASING TIMES

Day of incubation	Total c.p.m. in Hb
2	7,000
3	10,500
5	14,000
7	15,500
9	16,000
11	18,500

Iron-59 was added to all cultures on the first day.

In contrast, the proportion as well as the total amount of radioactivity incorporated into foetal haemoglobin increased during incubation (Figs. 1 and 2). The patterns found were similar when the analyses were carried out on starch gel electrophoresis using iron-59 or on starch grain electrophoresis with either label. A typical electrophoretic analysis on starch grain is shown in Fig. 3. To confirm that the radioactivity was in fact incorporated in Hb-F, this pigment was also isolated by alkali denaturation. Recoveries using the two techniques showed good agreement (Table 2).

To determine whether the increase in production of Hb-F was dependent on newly formed RNA, actinomycin

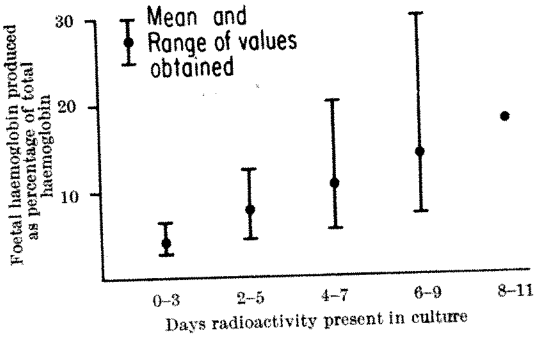

Fig. 1. Effect of length of incubation on rate of incorporation of radioactivity into foetal haemoglobin. Each point represents fifteen experiments except for days 8–11 when only one experiment was performed.

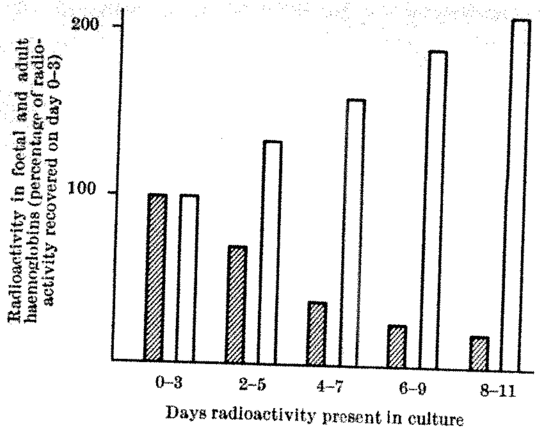

Fig. 2. Effect of length of incubation on incorporation of radioactivity into foetal (white columns) and adult haemoglobins (hatched columns). The columns for each comparison are based on the means of seven experiments. The amount of radioactivity present in foetal and adult haemoglobin on day 0–3 was taken as 100 per cent, and the amount of radioactivity in haemoglobin thereafter was expressed as the percentage of the radioactivity present on day 0–3. The ranges of foetal haemoglobin were as follows: days 2–5: 47–285 per cent; days 4–7: 47–350 per cent; days 6–9: 65–510 per cent; days 8–11: 190–265 per cent.

D was added to the cultures[5] to depress synthesis of DNA dependent RNA (0·1 ml. of actinomycin *D* dissolved in alcohol to give a final concentration of 5^{-10} molar). Two samples of a culture from the same individual, one with added actinomycin, were incubated in fourteen experiments and the counts in the various haemoglobin fractions were compared (Table 3). Addition of actinomycin *D* suppressed the production of foetal haemoglobin (mean suppression 88 per cent) more than that of adult haemoglobin (mean suppression 29 per cent). This difference was highly significant ($P < 0·01$) using the Wilcoxon rank order test.

Table 2. COMPARISON OF ALKALINE DENATURATION AND ELECTROPHORESIS IN ESTIMATION OF FOETAL Hb SYNTHESIS IN CULTURES

Experiment	Percentage alkali resistant haemoglobin*	Percentage F Hb* (elution from starch gel electrophoresis) Iron-59
1	18	21
2	28	33
3	1	5
4	2	3·5

* Percentages refer to the amount of radioactivity recovered from relevant fractions after culturing.

No differences in the amount of radioactivity incorporated into foetal haemoglobin in culture were noted when foetal calf serum was used rather than the patient's own serum. There was no relationship between the patient's clinical diagnosis and the amount of radioactivity incorporated into foetal haemoglobin. Essentially similar results were obtained using carbon-14 and iron-59 labelling.

Several mechanisms could account for the findings of increased Hb-F synthesis. (*a*) The culture conditions favour increased transcription of messenger RNA for the gamma chains of foetal haemoglobin. (*b*) Erythropoietic precursors which normally produce foetal haemoglobin were more resistant to cell death in culture conditions. (*c*) There was increased resistance of gamma chain messenger RNA to destruction in culture conditions. (*d*) Assuming that equal amounts of beta and gamma chain messenger RNA are made at all times and that control of haemoglobin synthesis is exerted at the ribosomal level[6], the conditions of culture favoured a shift towards translation of gamma chains by ribosomes.

The finding of an absolute increase in synthesis of Hb-F (Fig. 2) together with the more pronounced depression of Hb-F than of Hb-A synthesis with actinomycin (Table 3) suggests that increased transcription of messenger for gamma chains is the most likely explanation for our findings. Any one of the other mechanisms could also be operative. Whatever the mechanism, these studies indicate that haemoglobin synthesis may be active in culture for

PHYSIOLOGY

Powerful New Aggregator of Blood Platelets—2-Chloroadenosine-5′-diphosphate

ADENOSINE-5′-DIPHOSPHATE causes reversible aggregation of blood platelets in many mammalian species both *in vitro*[1,2] and *in vivo*[3,4] An optimal concentration of calcium ions[5] and the presence of one or more plasma factors[6] are required for aggregation to take place Studies by Born and Cross[2] of the aggregation of human platelets *in vitro* have shown that there is a linear relationship between the rate of aggregation and the logarithm of the concentration of ADP Aggregation *in vitro*, caused by ADP, is inhibited by adenosine, adenosine-5′-phosphate (AMP) and adenosine-5′-triphosphate (ATP) whether the platelets are human[2,7], rabbit[8] or pig[5]. It has been suggested by Clayton *et al* [9] that adenosine and AMP inhibit aggregation by occupying the ADP receptor

The nature of the ADP receptor and the mechanism by which ADP causes platelets to aggregate is not known although a number of different theories have been proposed Clayton *et al* [9] and Hellem and Owren[10] have suggested the interplatelet calcium bridge theory which envisages the binding of the purine moiety of ADP to a receptor on the surface of the platelet possibly by means of a plasma protein[10], and the bridging of the pyrophosphate moieties of adsorbed ADP molecules by calcium ions The inhibitory properties of adenosine, AMP and ATP are thought to be a result of their inability to form calcium bridges, though they still occupy the ADP receptor[9-11]

Salzman *et al* [12] have shown that platelets have an ATPase on their surface and they suggested that this "ecto-ATPase" provides the energy to maintain the platelets in the non-sticky state. ADP is thought to arrest this membrane regulatory process by product inhibition of the "ecto-ATPase", resultant changes in the membrane then permit the exposure of receptor sites which can take part in the platelet–platelet bridging by plasma protein and calcium ions

Robinson *et al* [13] and Mitchell and Sharp[14] have explained the phenomenon of the ADP-mediated platelet aggregation by postulating that the adsorption of ADP to the platelet surface alters the platelet's surface charge which normally causes platelets to repel each other

Recently another hypothesis has been put forward by Born[15], who found that dithiol compounds, such as dithiothreitol, inhibit the ADP-mediated aggregation of platelets He suggested that the interaction of ADP with its specific receptor produces a configurational change in a component of the platelet surface, and that this change is necessary for the formation between platelets and the plasma protein fibrinogen, of disulphide bonds which bring about the aggregation. Whatever the mode of action of ADP, whether it is initially simple adsorption to a specific receptor site on the surface of the platelet or the inhibition of a membrane regulatory enzyme, it seems most likely that ADP and adenosine act on the same receptor

2-Chloroadenosine has been found to be more potent than adenosine in inhibiting the ADP-mediated aggregation of human[16], rabbit[17] and sheep[18] platelets, and its action is more prolonged than that of adenosine The greater duration of action of 2-chloroadenosine can be explained, as suggested by Born[16], by the fact that it is probably not inactivated by plasma adenosine deaminase; 2-chloroadenosine is not deaminated by either rat kidney[19] or ox heart[20] adenosine deaminase The greater potency of 2-chloroadenosine compared with adenosine could be a result of a greater affinity of the analogue for the adenosine receptor If this is so, and adenosine and ADP do act at the same receptor, then the 2-chloro analogue of ADP would also be expected to have a greater affinity for the ADP receptor and to be an aggregator of greater potency than ADP

2-Chloroadenosine-5′-diphosphate (2-Cl-ADP) has been synthesized in this institute; it was isolated as the diammonium salt and was analytically pure Details of the synthesis will be reported elsewhere (G Gough and M H Maguire)

Aggregation studies with 2-Cl-ADP using sheep and human platelet-rich plasma have shown that 2-Cl-ADP is nine to ten times as potent as ADP

Sheep platelet-rich plasma was prepared as previously reported[18], and human platelet-rich plasma was prepared similarly from citrated blood collected from healthy volunteers The aggregation of platelets was measured by a modified version of Born's turbidimetric technique[5] In this method, the maximal change in optical density which could be induced by ADP was first recorded, and then the recording system was adjusted so that the change in optical density between non-aggregated and maximally aggregated platelet-rich plasma resulted in a standard reading on the recorder scale In this way results obtained from different batches of plasma could be pooled for statistical purposes To obviate further differences from one batch of platelet-rich plasma to another, comparative experiments were always carried out on the same day on the same batch of plasma

The aggregation of sheep platelet-rich plasma, brought about by varying concentrations of 2-Cl-ADP, was found to be reversible and dose dependent, just as the ADP-mediated aggregation is[18] Fig 1 shows the aggregation of sheep platelet-rich plasma by varying concentrations of 2-Cl-ADP. The log dose response curve for this aggregation was obtained by measuring the initial rate of the fall in optical density in platelet-rich plasma after the addition of 2-Cl-ADP. The log dose response curve for the ADP-mediated aggregation was obtained similarly Both log dose response curves are shown in Fig 2 and their parallel nature demonstrates that these two agonists are acting on the same receptor Both diphosphates in sufficient concentration cause complete aggregation This is indicated on the log dose response curves by the extrapolated broken line

Equimolar concentrations of 2-chloroadenosine and adenosine were found to inhibit the 2-Cl-ADP-mediated aggregation (Fig 3), and 2-chloroadenosine can be seen to be the more potent inhibitor Inhibition by both nucleosides is concentration dependent Log dose response curves were obtained from the aggregation curves for 2-Cl-ADP alone and in the presence of three concentrations of adenosine and 2-chloroadenosine In Fig 4 these log dose response curves form a family of parallel lines, indicating that the inhibition is competitive and that the agonist 2-Cl-ADP, and the antagonists 2-chloroadenosine and adenosine, are all acting on the same receptor The log dose response curves for the ADP-mediated aggregation in the absence of inhibitor and inhibited by adenosine and 2-chloroadenosine formed a similar family of parallel lines (Fig 5), showing the competitive nature of the inhibition by adenosine and 2-chloroadenosine of the ADP-mediated aggregation Both pairs of agonists and antagonists are acting on the same receptor.

Figs 2–5 show that the agonist and the antagonist in which the hydrogen of carbon 2 of the adenine moiety is replaced by chlorine have a greater affinity for the receptor than the parent compounds Values for the affinities of the antagonists were obtained from Arunlakshana and Schild plots of log $(x-1)$ versus the log of the concentration of the antagonist[21] where x is the ratio of the concentrations of inhibited agonist to uninhibited agonist which both give the same response. Data for the plots were obtained from Figs 4 and 5

The four Arunlakshana and Schild plots (Fig 6) form straight parallel lines, and in the case of the antagonist adenosine the plots obtained with both agonists, ADP and 2-Cl-ADP, are almost superimposable The plots obtained for the antagonist 2-chloroadenosine are not superimposable but not very different, and do overlap within the limits given by the standard errors. For clarity of illustration the standard errors are not shown The logarithmic values of the affinity constants, K_b, of the two antagonists are obtained from the intercepts with the line $\log (x-1)=0$, for adenosine, each agonist gives an identical value. 5 83, while for 2-chloroadenosine the intercept values are 6 43 with ADP as agonist and 6 40 with 2-Cl-ADP as agonist These values are expressed as affinity constants in Table 1 The two affinity constants obtained for 2-chloroadenosine, 0 27 × 10^7 and 0 25 × 10^7, are averaged

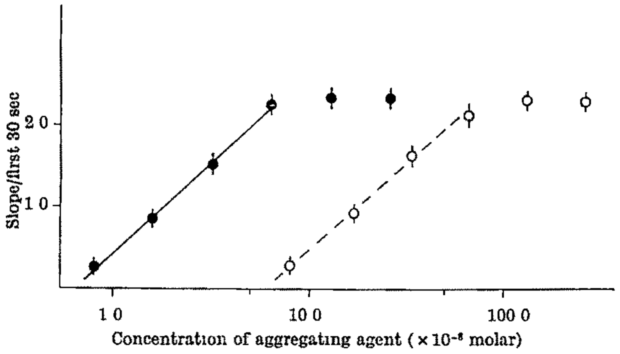

Fig 2 Log dose response curves for the aggregation of sheep platelet-rich plasma by ADP (○) and 2-Cl-ADP (●) Rates of aggregation were obtained from the initial slopes of the aggregation curves The points on each curve represent means of not less than ten experiments, the standard errors of the means are indicated by the vertical lines

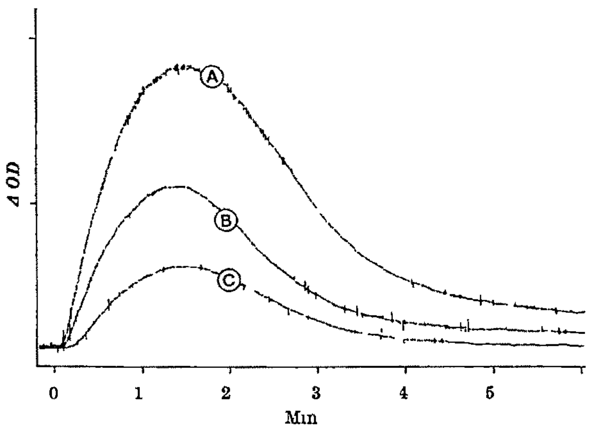

Fig 3 Changes in optical density of sheep platelet-rich plasma caused by 3 2 × 10^{-8} molar 2-Cl-ADP alone (*A*), and in the presence of 1 2 × 10^{-6} molar adenosine (*B*) and 1 2 × 10^{-6} molar 2-chloroadenosine (*C*) Adenosine and 2-chloroadenosine were added to the platelet-rich plasma 2 min before the addition of 2-Cl-ADP at zero time

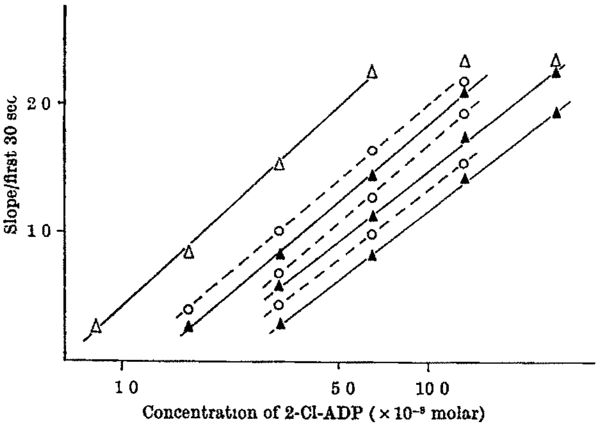

Fig 4 Log dose response curves for the aggregation of sheep platelet-rich plasma by 2-Cl-ADP alone (△), and in the presence of adenosine and 2-chloroadenosine Concentrations of adenosine (○) reading from left to right were 1 2, 2 4 and 4 8 × 10^{-6} molar, concentrations of 2-chloroadenosine (▲) reading from left to right were 0 45, 0 9 and 1 8 × 10^{-6} molar

Table 1 AFFINITY CONSTANTS K_a AND K_b, OF AGONISTS AND ANTAGONISTS FOR THE PLATELET ADP RECEPTOR

2-Cl-ADP	5 61 × 10^7
ADP	0 58 × 10^7
2-Chloroadenosine	0 26 × 10^7
Adenosine	0 07 × 10^7

Affinity constants can also be obtained for the agonist ADP and 2-Cl-ADP from the log dose response curves Because both agonists will elicit the maximum aggregation possible, and because there would seem to be negligible diffusion barriers for the agonists to pass through before having access to the platelet receptors, it may be assumed that the response, that is, the percentage of maximum aggregation, is proportional to the number of receptors occupied At 50 per cent response, half the receptors will be occupied and the affinity constant K_a will be the reciprocal of the concentration of the agonist The values of K_a obtained in this way from Figs 4 and 5 are also given in Table 1 The values show that the agonists have a greater affinity for the ADP receptor than the antagonists and that in the case of the agonists a chlorine substituent in the 2 position increases affinity 9 7-fold, while

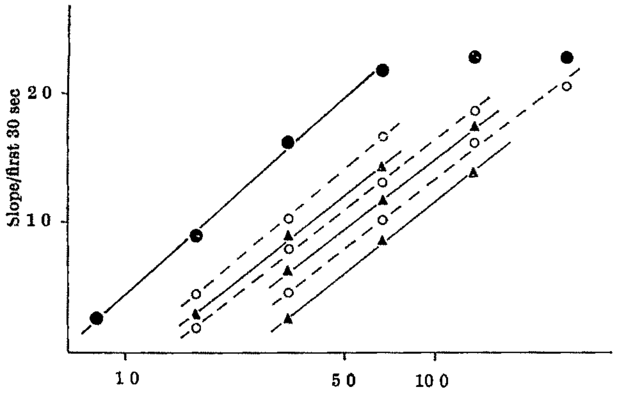

Fig 5 Log dose response curves for the aggregation of sheep platelet-rich plasma by ADP alone (●), and in the presence of adenosine (O) and 2-chloroadenosine (▲), in concentrations as described for Fig 4

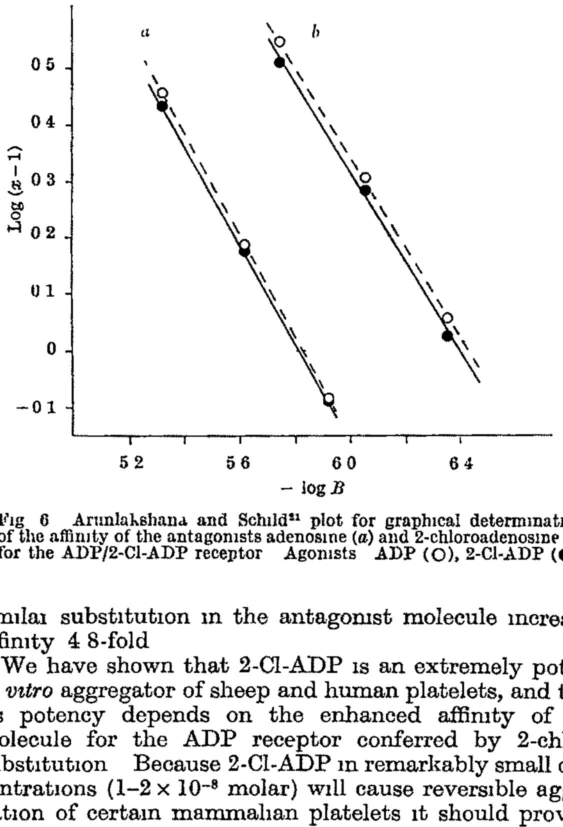

Fig 6 Arunlakshana and Schild[21] plot for graphical determination of the affinity of the antagonists adenosine (a) and 2-chloroadenosine (b) for the ADP/2-Cl-ADP receptor Agonists ADP (O), 2-Cl-ADP (●)

similar substitution in the antagonist molecule increases affinity 4 8-fold

We have shown that 2-Cl-ADP is an extremely potent *in vitro* aggregator of sheep and human platelets, and that its potency depends on the enhanced affinity of the molecule for the ADP receptor conferred by 2-chloro substitution Because 2-Cl-ADP in remarkably small concentrations ($1-2 \times 10^{-8}$ molar) will cause reversible aggregation of certain mammalian platelets it should prove a valuable tool for research into the mechanism of ADP-mediated platelet aggregation

We thank Professor R H Thorp for his continued interest in these studies

Sites of Action of some Partial Agonists on the Isolated Guinea-pig Ileum

It is well known that if in a homologous series of drugs a special group is changed by heavier ones, they gradually change from agonists through partial agonists into competitive antagonists[1] It has been reported that isoamyl acetate, its analogues[2] and pilocarpine[3], some of which are partial agonists, contract the isolated guinea-pig ileum through the liberation of acetylcholine on the one hand, and antagonize the action of released acetylcholine on the other hand, when they combine with the acetylcholine receptor The sites of action of partial agonists, however, have never been studied precisely, and so we have investigated the effects of cooling, cocaine, morphine and hexamethonium on the actions of two series of drugs which are esters of choline and dimethylaminoethanol

Strips of male guinea-pig ileum (3–4 cm long) were suspended in Lock–Ringer solution at 32° C and bubbled with air The responses of the ileum to test drugs were recorded isotonically on a smoked paper The results given are the means of at least ten experiments

The drugs are listed in Table 1 Pentanoylcholine, hexanoylcholine, benzoylcholine, dimethylaminoethyl butyrate and pilocarpine were partial agonists All drugs listed and also nicotine, and those drugs which affect the nerve structures, contracted the ileum through the acetylcholine receptors because their responses were antagonized by 10^{-8}–10^{-7} molar atropine The responses to the partial agonists and nicotine were greatly reduced, or abolished, by cooling the ileum to 12° C for 1–2 h, or by 5 min of treatment with cocaine (5×10^{-5} molar), while the responses to the agonists such as acetylcholine were not much affected by those treatments The responses to drugs which contracted the smooth muscle by stimulating the cholinergic nerve structures were greatly reduced by cooling the ileum, by anoxia or by cocaine[4] Furthermore, the responses to the partial agonists, with the exception of pilocarpine, were much reduced by 5×10^{-5} molar hexamethonium after 5 min, by 3×10^{-5} molar morphine after 2 min or by 10^{-6} molar tetrodotoxin after 5 min The results indicate that the site of action of the partial agonists is in the nerve structures of the ileum, the partial agonists, except with the ion of pilocarpine,

Table 1 INTRINSIC ACTIVITIES AND AFFINITIES (pD_2 AND pA_2)

C O [CNCCOC–R]$^+$X$^-$ C	R	X	At 32° C Intrinsic activity	At 32° C pD_2	At 12° C pA_2 (agonist = ACh)
ACh	CH_3	Cl	1 00	7 12	
PrCh	C_2H_5	I	1 00	5 65	
BuCh	n-C_3H_7	I	1 00	4 50	
PenCh	n-C_4H_9	I	0 66	4 18	4 08
HeCh	n-C_5H_{11}	I	0 54	4 58	4 51
BeCh	C_6H_5	I	0 52	3 39	4 45
O [^C_CNCCOC–R]HCl					
DMAEAc	CH_3		1 00	5 25	
DMAEBu	n-C_3H_7		0 70	3 90	3 80
Pilocarpine			0 87	6 44	6 27

Intrinsic activity is maximal contraction by test drug/maximal contraction by ACh seem to stimulate the ganglion cells and accelerate the liberation of acetylcholine which is depressed by morphine or strychnine In addition, pilocarpine also stimulates the nerve structures and liberates acetylcholine through a mechanism which is unaffected by morphine or strychnine[3,5]

The affinities of the agonists were expressed as the pD_2 values or the negative logarithm of the concentration which produced 50 per cent maximal contraction of muscle The competitive inhibitory activities were expressed as the pA_2 values which were calculated from the shift of a dose response curve of an agonist[6] All the partial agonists, however, displaced a dose response curve of acetylcholine towards greater concentrations in the experiments at 12° C The pA_2 values of the partial agonists were calculated from a shift of the dose response curve of acetylcholine in the experiments at 12° C The intrinsic activities and affinities are summarized in Table 1 The pA_2 values of competitive inhibitors against acetylcholine were little affected by cooling the ileum to 12° C, so the pA_2 values of the test drugs listed in Table 1 may represent their affinity for the acetylcholine receptor on the smooth muscle (ref 2 and unpublished work of Takagi, Takayanagi and Maezima) The responses to pentanoylcholine or a partial agonist were inhibited more by dibenamine (3×10^{-5} molar) than those to acetylcholine[1] This suggests that the responses to the partial agonists are antagonized by what may be a synergism of their own atropine-like action plus the anti-acetylcholine action of dibenamine, on the other hand, the responses to the pure agonists may be considered to be antagonized by an unaided anti-acetylcholine action of dibenamine As suggested, partial agonists may contract the guinea-pig ileum by liberating acetylcholine from the cholinergic nerves and antagonize an action of the acetylcholine, which they have released, by their atropine-like action

To confirm this hypothesis, the mode of action of an equivalent mixture of acetylcholine and atropine was tested The intrinsic activity or the ratio of the maximal contraction produced by the mixture to that produced by acetylcholine is about 0 7 and the concentration which produced 50 per cent of the maximal contraction was 10^{-8} g/ml Furthermore, 3×10^{-5} molar dibenamine inhibited the responses to the mixture more than the responses to acetylcholine

Daily Rhythm in the Noradrenaline Content of Rat Hypothalamus

The noradrenaline content of several organs of the rat has been shown to vary during each 24 h period[1,2] Almost all of the catecholamine in these organs (pineal, salivary gland and liver) is located not in the parenchymal tissue but within the nerve endings of sympathetic axons[3] Noradrenaline is also concentrated in several regions[4-6] of the brain, where it is found within both nerve endings and cell bodies It will be shown that in normal lighting conditions the noradrenaline concentrations in the anterior and posterior rat hypothalamus are not constant but, like the catecholamine in peripheral organs, depend on the time of day when the tissue is sampled.

Three separate studies were performed during two summers, each used female Sprague–Dawley rats weighing 160–180 g The animals were kept in a controlled light environment (25–50 ft.-candles of illumination, provided by cool-white fluorescent bulbs) for at least 2 weeks before they were killed The lights were turned on for 12 h starting at 6 00 a m or 7.00 a m Groups of between four and nine animals were killed by decapitation after 5 5 h of light, at the end of the light period, after 6 h of darkness or after 11 5 h of darkness The brains were removed and chilled, five regions (anterior hypothalamus, posterior hypothalamus, striatum, midbrain and thalamus-subthalamus) were dissected, using a technique similar to that described by Glowinski and Iversen[7] The lateral cuts bounding the hypothalamus were slanted toward the midline in order to avoid including subthalamic structures (such as Forel's fields) The hypothalamus was then subdivided into anterior and posterior portions by a transverse cut 2 mm caudal to the optic chiasma The weights of each region of the brain were relatively reproducible from animal to animal, their standard deviations, among the sixty-seven rats studied ranged from 10 to 21 per cent of their means

Noradrenaline was assayed in samples of individual rat brains Each region was homogenized in 5 ml. of perchloric acid (0 4 normal) After centrifugation, the supernatant was transferred to a beaker containing 200 mg of alumina which had been washed with acid, 5 ml. of 2 normal ethylenediamine tetraacetic acid and 15 ml of sodium bisulphite. The *p*H was adjusted to 8 6 with concentrated sodium hydroxide and the contents of the beaker were poured over a column containing an additional 200 mg of alumina which had been brought to *p*H 8·6 The column was washed with 0 2 normal sodium acetate and with glass-distilled water, the noradrenaline was then eluted with 3 ml of 0 2 normal acetic acid and assayed spectrophotofluorometrically[9] The recovery of added noradrenaline averaged 67 per cent

In each of the three experiments, the mean noradrenaline concentration of each brain region was calculated, and individual measurements taken at different times of day were expressed as percentages of the daily mean value for the region Data from all three experiments were pooled, and the statistical significance of temporal differences was determined using a *t* test Similar results were obtained in all three experiments The regional concentrations of noradrenaline are shown as a function of hour of the day in Table 1

Significant daily rhythms were observed in the anterior hypothalamus and the posterior hypothalamus The noradrenaline contents of both regions were greatest at the middle of the daily dark period, in the anterior hypothalamus, the catecholamine concentration was low throughout the light period, in the posterior hypothalamus, the nadir was reached at the end of the dark period In both regions, the magnitude of the daily change was 22–24 per cent Daily noradrenaline

Table 1 NORADRENALINE CONCENTRATION OF VARIOUS BRAIN REGIONS AT DIFFERENT TIMES OF DAY

Brain region		Mean noradrenaline concentration γ/g	Time brain removed 5 5 Light	12 Light	6 Dark	11 5 Dark
			Noradrenaline concentration (per cent of mean ± *SE*)			
Anterior hypothalamus	63	1 454	92 6 ±5 3	92 1* ±4 7	112 8 ±5 5	103 3 ±3 9
Posterior hypothalamus	67	1 094	103 2 ±5 7	99 6 ±7 6	110 2 ±6 0	88 7* ±4 2
Midbrain	66	0 398	95 3 ±5 6	93 8 ±5 3	102 4 ±5 1	108 3 ±8 0
Striatum	60	0 224	98 1 ±5 6	106 1 ±6 5	101 8 ±8 0	96 3 +7 2
Thalamus-subthalamus	48	0 226	101 3 ±16 0	91 9 ±10 6	84 1 ±8 4	122 5 ±21 5

* $P < 0\ 01$ Noradrenaline content differs significantly from that observed after 6 h of darkness

fluctuations of greater amplitude were found in the thalamus-subthalamus, but these changes were not statistically significant (Table 1). A daily noradrenaline rhythm has been demonstrated in the lateral hypothalamus of the cat[10]. In the present experiment, the region designated thalamus-subthalamus contained the lateral hypothalamic area, as well as the thalamus. It is possible that a daily rhythm exists in lateral hypothalamic noradrenaline and that the rhythm was obscured in the present study because the hypothalamic tissue was diluted with relatively large amounts of thalamus. The noradrenaline concentrations in the rat midbrain and striatum did not vary during the day; similar findings have been reported in the cat[10].

The neuroanatomic structures responsible for hypothalamic noradrenaline rhythms are not known, nor are the biochemical mechanisms which generate them clear. The increased concentration of the neurotransmitter during the dark period could be caused by enhanced noradrenaline synthesis, decreased release of the amine, or a decrease in its rate of intracellular metabolism. It seems likely that the amount of hypothalamic noradrenaline which can be liberated by a drug also depends on the time of day that the drug is administered. If this is true, it is possible that psychotropic drugs (such as amphetamine) which produce their effects by releasing brain noradrenaline may show time-dependent variations in potency.

We thank Dr Julius Axelrod for helpful discussions, and Mrs Helen Hunt for technical assistance. These studies were supported by the US Public Health Service.

Thermoregulation in Tortoises

ALTHOUGH reptiles in a laboratory cage may show feeble powers of thermoregulation, it is now known that, when active in natural conditions, their body temperature is often regulated by behavioural means at a thermal level higher than that of many mammals[1]. Tortoises are no exception and sun themselves when the air is cool. Experiments on young desert tortoises, *Testudo sulcata* Miller (= *T. calcarata* Schn.), have shown that water loss by evaporation increases greatly in dry air at temperatures above 40°–41° C. At ambient temperatures of 55° C the body temperature rises rapidly to about 40.5° C, at which level it is maintained by copious salivation which wets the head, neck and front legs. Although they do not usually take water when supplied with green food, these tortoises drink deeply after such experiments.

Application of Laser Interferometry to Physiological Studies of Excitable Tissues

INTERFEROMETRIC techniques offer a sensitive means of measuring small displacements, film thickness and changes in refractive index. By applying interferometry to studies of excitation processes, Kayushin and Lyudkovskaya[1,2] and Lyudkovskaya[3] reported that they had detected small movements of frog sciatic nerve in association with excitation. This communication describes a technique of applying laser interferometry to the investigation of various excitable tissues; we have tried to detect small movements accompanying the action potentials of fresh water algae (*Nitella*) and frog and lobster nerve trunks.

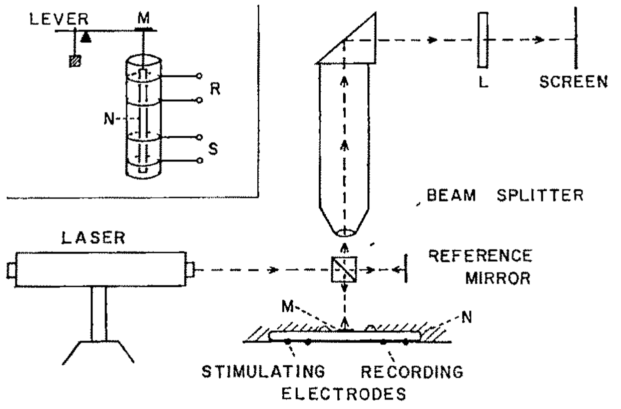

Fig. 1. Schematic diagram showing the interferometry set-up used to examine excitable tissue for the presence of small movements associated with the production of action potentials. *M* represents a small mirror placed on the surface of a *Nitella* internode or a nerve trunk (*N*). Two 'Vaseline' partitions were used to separate the middle section of the tissue from the lateral portions where the platinum wire stimulating and recording electrodes were placed. *L* represents a cylindrical lens used to focus the interference pattern on to the screen of the oscilloscope used for recording the action potential. The inset illustrates the technique used to examine changes in the length of an excitable tissue (*N*) in response to electric stimulation. Stimulating (*S*) and recording (*R*) electrodes were made of rings of platinum wire (separated by approximately 10 mm) placed near the wall of the cylindrical 'Lucite' chamber (filled with sea water diluted by a factor of 2,000).

A helium-neon gas laser (Perkin-Elmer, model 5200) served as a source of continuous, coherent, plane-polarized light (0.6328μ wavelength). An interference objective attachment (W. Watson and Sons, England) was modified by removing the condenser lens system and was fitted to a standard monocular microscope. The experimental set-up is illustrated schematically in Fig. 1. The laser beam was split in two by means of a half-silvered mirror. Interference was obtained between one portion of the beam reflected back from a reference surface mirror to the half-silvered mirror and the other part of the beam reflected from a small surface mirror attached to the biological preparation. A prism at the top of the microscope tube and a cylindrical lens were used to focus the resulting interference pattern onto the upper half of a cathode ray oscilloscope screen. In this manner, the interference pattern and the electrical response of the tissue to stimulation (displayed on the lower half of the oscilloscope screen with a standing beam) could be recorded simultaneously on moving photographic film.

In one series of experiments, the small surface mirror (0.5 mm^2) was placed directly on the (moist) surface of a *Nitella axillaris* internode, frog sciatic nerve or lobster circumoesophageal connective (Fig. 1). These excitable tissues were mounted horizontally in a 'Lucite' chamber provided with two pairs of platinum electrodes (one pair

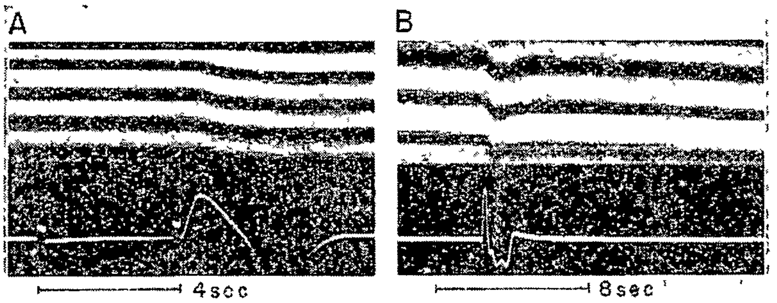

Fig 2 Shifts of interference pattern representing small movements associated with the excitation process in *Nitella* internodes Record *A* was obtained by using a surface mirror placed directly on the internode (horizontal arrangement) Note that a barely sub-threshold electric shock produced no detectable movement of the interference pattern Record *B* was taken from a *Nitella* internode mounted in the vertical chamber (see inset, Fig 1) For both experiments, the fluid medium was sea water diluted by a factor of 2,000 The tension applied to the *Nitella* cell in the vertical chamber was approximately 0 25 g A shift of the interference pattern of one full period corresponds to a 0 3164μ movement of the mirror The room temperature was 20° C

for stimulation, the other for recording action potentials) The mirror was placed on the preparation between the electrode pairs, this portion of the chamber contained only sufficient fluid to prevent the preparation drying After adjusting the two mirrors to give an interference pattern, brief pulses of current were delivered to the tissue through the stimulating electrodes In this way, a transient shift in the interference pattern, representing a small displacement of the surface of a *Nitella* internode, was detected whenever an action potential was produced (Fig 2*A*). There was no detectable shift in the interference pattern when the stimulating current failed to produce an action potential (that is, when the stimulus was sub-threshold) The displacement associated with an all-or-none action potential was generally between 0 1 and 0 3μ at the peak The direction of movement of the cell surface was always downward (compatible with a reduction in diameter of the *Nitella* cell) The internodes of the *Nitella* used were 350–450μ in diameter and 30–40 mm in length Similar experiments with frog and lobster nerve were performed, but no movement was detected even when a train of impulses (50 shocks/sec) was evoked

Reversible changes in the length of the *Nitella* cell with excitation were also observed when the internode was mounted vertically in a 'Lucite' chamber containing sea water diluted by a factor of 2,000 (inset, Fig 1) One end of the cell was secured to the bottom of the chamber and the other end was tied to a micro-lever with fine thread Interference patterns were obtained with a surface mirror attached to the lever A typical record obtained in these conditions is shown in Fig 2*B* The reversible shift in the interference pattern represents a shortening of the internode with excitation The observed shortening ranged between 0 1 and 0 3μ at the peak The recovery process (that is, the process of returning toward the initial length following shortening) was seen to start during the falling phase of the extracellularly recorded response (This phase of the extracellular response roughly coincides with the peak of an intracellularly recorded action potential) The initial, rapid phase of recovery was followed by a late, gradual recovery phase The results obtained by this method are consistent with those of Kishimoto and Ohkawa[4], who detected an average shortening of *Nitella* internodes of 0 1μ using a sensitive micro-lever technique (without interferometry).

When frog or lobster nerve was used in the vertical chamber, no detectable change in length was observed during repetitive stimulation (50 shocks/sec) At present, the reason for our failure to detect small movements during the excitation of these nerves is not clear An attempt is now being made to improve the sensitivity of our system by using a photomultiplier instead of the present photographic technique for detecting shifts of the interference pattern The relationship between the present experimental finding in *Nitella* and the mechanism of excitation in this alga (see, for example, Mullins[5]; Mailman and Mullins[6]; Kishimoto and Ohkawa[4]) remains to be clarified

RADIOBIOLOGY

Composition of Trabecular Bone in Children and its relation to Radiation Dosimetry

Trabecular bone is a composite tissue containing both bone marrow and bony tissue, but the radiation dose to the composite tissue from a β-emitting bone seeking nuclide is, to a first approximation, proportional to the amount of bone present Children are of particular interest in this respect because of the rapid turnover of their bone mineral[1] We report here the results of chemical analyses of specimens of trabecular bone from young children, which enable the amount of bone in trabecular bone tissue to be estimated

Information about the physical and chemical composition of trabecular bone is sparse in the literature Erf[2] reports chemical analyses for the phosphorus content of compact bone and trabecular bone specimens (vertebral

Table 1. CALCIUM AND PHOSPHORUS CONTENT OF TRABECULAR AND CORTICAL BONE AND BONE MARROW

Specimen	Ratio, ash weight/wet weight	Percentage calcium by weight (in ash)	Percentage phosphorus by weight (in ash)	Calcium content, mg/g wet weight	Phosphorus content, mg/g wet weight
Vertebral trabecular bone tissue (*A*)	0.139	34.2	18.2	47.5	25.3

bodies), taken from a case of lymphatic leukaemia, in a patient who died at 65. Jones and Ellis[3] found that trabecular bone tissue, taken after death from the vertebral bodies of two adults, had a density of 1.1 g/cc. From the data given in these references, and using reasonable assumptions, it may be calculated that the proportion of bone by weight in trabecular bone tissue is 20–30 per cent. It should be remembered, however, that these experiments were made primarily for other purposes.

Calculations of the gravimetric composition of trabecular bone tissue have been made from measurements of the dimensions of the bone marrow cavities and the bony trabeculae, and lead to significantly higher estimates of the proportion of bone. For example, the trabecular bone model proposed by the International Commission on Radiological Units and Measurements (ICRU)[4] corresponds to a proportion of bone by weight of more than 65 per cent. None of this work was on child bone, and the results are not consistent.

Our measurements were made on bone specimens taken at post mortem from two children, aged 17 and 20 months. The children died in hospital, following acute respiratory illnesses. The bone specimens were considered to approximate closely to normal bony tissue and were stored at −20° C. Lumbar vertebrae were obtained from both children and a femur from one child. Trabecular bone tissue was dissected out from the vertebral bodies and from the upper end of the femur. Care was taken to avoid including any cartilage in the trabecular bone samples. The marrow cavity of the femur provided a small specimen of red bone marrow (1.3 g), and specimens of compact (cortical) bone were obtained from the femur shaft.

Specimens were weighed, dried and finally dry ashed in a muffle furnace up to a maximum temperature of 750° C. The resulting ash specimens were weighed after cooling in a desiccator. Phosphorus was determined in the ash specimens by the well known procedure using ammonium molybdate. Calcium was determined gravimetrically as the oxalate[5]. Analyses were carried out in duplicate and the coefficient of variation of the phosphorus method was 1 per cent and of the calcium method 0.2 per cent. The present results may be slightly below this standard because of the small weights of the ash samples. Results are summarized in Table 1, expressed as percentage of calcium and phosphorus, by weight, in the ash. The last two columns give the calcium and phosphorus contents of the original samples, and are obtained from the chemical analyses together with the known ash weight and wet weight of each specimen.

The calcium and phosphorus contents of trabecular bone ash are seen to be very similar to those of compact bone ash. Both approximate quite closely to a simple stoichiometric hydroxyapatite $[Ca_3(PO_4)_2]_3$, $Ca(OH)_2$, which contains 39.9 per cent calcium and 18.5 per cent phosphorus by weight[6]. Our results are also in accordance with those of Gong *et al.*[7] In work with cortical bone, and vertebral trabecular bone free of marrow, from ten adult humans, these authors found the density of cortical bone to be 1.991 g/cc and of trabecular bone 1.924 g/cc. For present purposes we may assume that the bone in trabecular bone tissue is quantitatively the same as compact bone.

We assume also that marrow in trabecular bone has the same calcium and phosphorus content as femur shaft bone marrow. A comment should be made on our bone marrow results; it is very difficult to be certain that no tiny spicules of bone remain in a sample of marrow taken from the marrow cavity in a long bone. The presence of a small percentage of bone markedly affects results for the calcium and phosphorus content of bone marrow, and possibly explains widely differing values quoted in the literature[8]. For an organ roughly comparable in cellularity with bone marrow, namely spleen, ICRP[9] gives the calcium content as 0.084 mg/g and phosphorus as 2.2 mg/g. The contribution of the bone marrow to the calcium and phosphorus content of trabecular bone tissue is therefore small.

The two assumptions discussed here allow the amount of bone in trabecular bone tissue to be obtained by proportion from the calcium measurements, or from the phosphorus measurements, or more simply from the ash weights, with the results shown in Table 2. The explanation of the small differences between these results is not clear, but for present purposes it is sufficient to consider that one-quarter the weight of trabecular bone tissue is bone.

Table 2. PROPORTION OF BONE IN TRABECULAR BONE TISSUE IN YOUNG CHILDREN

Method	Weight of bone in trabecular bone tissue (mg/g)
Calcium content	235
Phosphorus content	258
Ash weights	254

Erf's[2] analyses for phosphorus are comparable with ours, for he obtained 20.8 mg/g wet weight in vertebral bodies, and around 90 mg/g in the diaphyses of the tibia and femur, in his 65 yr old leukaemia patient. The density measurements of Jones and Ellis[3] are also compatible with our results: they found 1.1 g/cc for the density of adult vertebral trabecular bone tissue, and we would calculate 1.14 g/cc by using a density of 1.924 (ref. 7) for trabecular bone and 1.0 for marrow.

If trabecular bone tissue is formalized into a regular cubic lattice, following ICRU[4], we may calculate the thickness of the bony walls surrounding each cube of bone marrow by using the results of Table 2. If the cubes of marrow have sides of 400μ, for example (ICRU quote a range of 200–950μ), the thickness of the bony wall is only about 20μ. This is the smallest observed thickness of bone trabeculae according to ICRU, the largest thickness they report is 250μ.

In conclusion, chemical analyses of bones from children about 18 months old show that the proportion of bone by weight, in trabecular bone tissue from vertebral bodies and the upper end of the femur, is almost exactly 25 per cent. This finding supports a previous chemical analysis and a density measurement of adult trabecular bone tissues, but disagrees with estimates made from geometrical measurements of bone sections.

We thank Professor T. Crawford and Dr W. A. Aherne for the bone specimens, and W. Fletcher and A. Hughes for carrying out the chemical analyses.

BIOLOGY

Regulation of Albumin Synthesis and Catabolism by Alteration of Dietary Protein

There is good evidence that catabolism of albumin is slowed in conditions of low-protein feeding and in clinical states of protein deficiency, for example, kwashiorkor[1-3]. There is less certainty about alterations in the rate of synthesis, measurement of which is usually derived indirectly from the metabolic behaviour of isotopically labelled albumin[3,4].

It has also been difficult to define the processes which regulate albumin synthesis and catabolism in states of protein deprivation. It has been particularly difficult to prove whether the adaptive changes reflect a response to altered concentration or mass of plasma albumin, or whether they are a more direct response to reduced availability of dietary protein[3,5]. In an attempt to resolve this difficulty, we have made serial measurements of the plasma albumin pool and of synthesis and catabolic rate in rats given diets containing little or no protein. Similar studies were made in rats re-fed a normal diet after being deprived of protein.

The plasma albumin pool was calculated from the product of albumin concentration and plasma volume (determined by isotope dilution using ^{131}I-albumin). Synthesis rate was measured by the method of McFarlane based on the relative rates of incorporation of carbon-14 into urea and into the guanidine carbon of albumin arginine[6,7]. Rat albumin labelled with iodine-131 was administered intravenously to measure catabolic rate which was calculated from daily urinary loss of radioactivity, derived indirectly from serial whole-body counts and expressed as a function of plasma specific activity. The method is valid even in an unsteady state which might exist in these experimental conditions[4]. ^{131}I-albumin was prepared by ammonium sulphate precipitation and labelled by the iodine monochloride method[8].

Male albino rats of Wistar strain, housed in conditions of controlled temperature and humidity, were fed one of three diets: normal protein diet consisting of 20 per cent mixed protein, low-protein diet consisting of 5 per cent mixed protein, and a protein-free diet. All were isocaloric on a weight basis. Appropriate vitamin and mineral supplements were added to the low-protein diet and to the protein-free diet. The rats were allowed free access to water. Iodide was added to the water when the catabolic rate was being measured in order to block uptake of iodine-131 by the thyroid. We set out initially to test the agreement between the synthesis rates, measured with ^{14}C-carbonate, and the catabolic rates measured with ^{131}I-albumin in animals under the same nutritional conditions. The two rates in this case should be equal. Catabolic rate was determined daily for 14 days on twenty control rats receiving the normal protein diet. At the end of this period ^{14}C-carbonate was injected to measure the synthesis rate. Five groups of four rats were studied and plasma from each group was pooled. Table 1 shows excellent agreement between synthesis rate and catabolic rate in these animals. There was also good correlation for similar figures derived from five rats studied individually after 60 days on the low-protein diet (Table 2). In this case both the synthesis rate and the catabolic rate are significantly lower than the control values ($P < 0.001$), which indicates adaptation to a lower protein intake.

Table 1. COMPARISON OF ALBUMIN SYNTHESIS AND CATABOLIC RATES DERIVED BY TWO INDEPENDENT METHODS, IN TWENTY RATS ON NORMAL PROTEIN INTAKE

Group	Synthesis rate (mg/h/300 g of rat)	Catabolic rate (mg/h/300 g of rat)
1	12.8	12.9
2	11.7	10.7
3	11.2	10.4
4	11.6	11.9
5	11.1	10.0
Mean	11.7	11.2

Each figure represents pooled values from a group of four rats.

Table 2. COMPARISON OF ALBUMIN SYNTHESIS AND CATABOLIC RATES IN FIVE RATS STUDIED INDIVIDUALLY AFTER 60 DAYS OF LOW-PROTEIN DIET

Rat	Synthesis rate (mg/h/300 g of rat)	Catabolic rate (mg/h/300 g of rat)
1	4.3	2.0
2	4.0	3.5
3	3.5	3.1
4	1.7	2.2
5	2.6	5.6
Mean	3.2	3.3

Serial measurements were made on rats on a protein-free diet, in order to study the sequence in which these changes occur. Synthesis rate was measured daily for 8 days and on days 10 and 12, each assay being based on pooled plasma from a group of four rats. Simultaneous estimations on groups of rats fed on a normal protein diet provided controls for each assay. In a repeat experiment, duplicate values for synthesis rate were obtained for days 3, 4, 6, 7 and 10. Daily catabolic rate was measured on eleven rats, previously given ^{131}I-albumin, for 4 days before and 9 days after being fed on a protein-free diet.

The timing of adaptation to protein repletion was also studied. Rats were fed on a protein-free diet for 12 days, and then allowed free access to a normal diet. On days 1, 3, 4, 5 and 7 after resumption of the normal diet, synthesis rate was determined, plasma from a group of four rats was again pooled for each assay. Catabolic rate was measured on seven rats on the last 2 days of the protein-free diet and daily for 12 days when they were on a normal protein diet.

Overall results of this depletion and repletion experiment are presented in Fig. 1. Solid lines for albumin concentration, and broken lines for synthesis rate during depletion and catabolic rate during repletion, were calculated by the least means squares method, and are included to indicate the probability of gradual change

The concentration of plasma albumin and of the intravascular pool mass decreased in a similar way The change in pool mass was all caused by a decrease in albumin concentration, for the plasma volume remained constant throughout the experiment Catabolic rate was maintained for 6–7 days (by which time synthesis rate and albumin concentration were much reduced) before falling precipitously On repletion there was an immediate increase in the synthesis rate to normal or above-normal values This change was reflected by a gradual rise in plasma albumin concentration (and pool mass) Catabolic rate rose slowly after what appeared to be a slight lag

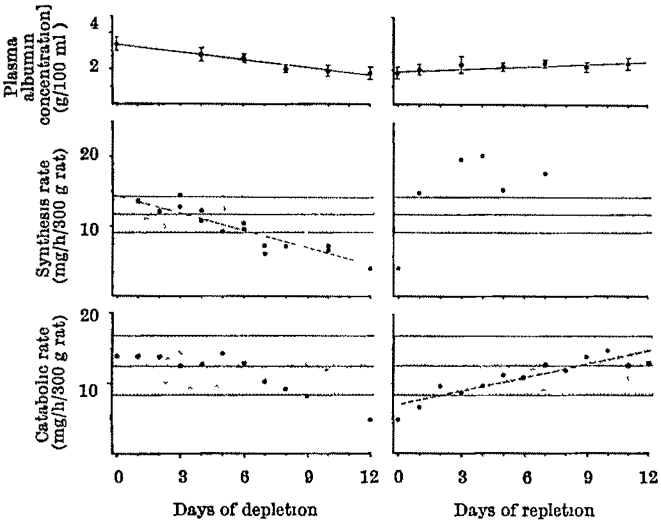

Fig 1 Serial measurements of plasma albumin concentration, synthesis and catabolic rates in rats during depletion and repletion of dietary protein Shaded areas indicate means ± 2 *S D* derived from thirty-eight normal rats

These changes seem to demonstrate conclusively the existence of separate, independent control mechanisms for albumin synthesis and catabolism, at least in our experimental conditions These results seem to support the following hypothesis Reduction or withdrawal of dietary protein causes a reduction in the synthesis rate of albumin, presumably through a reduction in the availability of amino-acids Catabolism continues at a normal rate, so that a gradual decrease in the concentration of plasma albumin and pool size occurs At some critical level, reduction in catabolic rate follows This is probably an attempt to conserve the albumin pool in the face of impending depletion If adequate dietary protein is now made available, synthesis rate increases abruptly The concentration of plasma albumin and the size of the pool gradually increase until there is no need for a compensatory decrease of the catabolic rate and normal values are re-established

Association between *Pandalus borealis* and Fine-grained Sediments off Northumberland

The deep-sea prawn, *Pandalus borealis*, is a north-boreal species It is found in the North Atlantic, North Pacific and Arctic Oceans It also occurs in the northern part of the North Sea, and populations off the Norwegian coast are exploited commercially[1] On the British side of the North Sea, *P borealis* occurs off northern Scotland and off Northumberland The Northumberland population is probably at the southern limit of the range of this species[2].

The first record of *P borealis* in the North Sea was by Kemp[3], who noted that several specimens had been taken in 1907 in 57 fathoms off Northumberland It has been taken on numerous occasions since then but never, apparently, in very large numbers Allen[2] published an extensive study in 1959, and reached the conclusion that although numbers of prawn were present off the Northumberland coast it was unlikely that the population could support a commercial fishery Elsewhere, *P borealis* can occur in considerable quantities on soft mud bottoms in deep-water troughs[1,4,5], but off the Northumberland coast it seemed that, even though both the bottom topography (Fig 1) and sediment distribution (Fig 2) were suitable, large concentrations of *P borealis* did not occur

In September 1966 the distribution of prawns and bottom deposits was surveyed, and in March 1967 a partial survey was made of the prawn distribution. Prawn samples were taken with a 40 mm mesh otter trawl (ground rope, 82 ft) towed for 0 5 h, and sediment

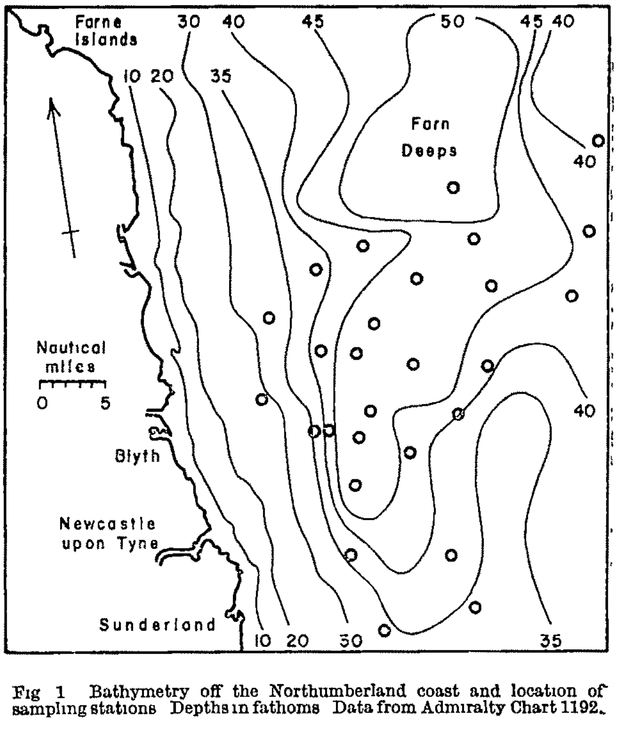

Fig 1 Bathymetry off the Northumberland coast and location of sampling stations Depths in fathoms Data from Admiralty Chart 1192.

samples were taken with a 0.2 m^2 Van Veen grab. The survey was carried out from the research vessel Platessa (Ministry of Agriculture, Fisheries and Food), a wooden side trawler of 90 ft overall length. The locations of the sampling stations (September 1966) are shown in Fig. 1.

The distribution of bottom sediments was published by Buchanan[6] in 1963. He found that near the coast, and to about 10 miles offshore, the bottom is either bare rock or sand and gravel, but further offshore there is a large area of very fine sand. This fine sediment occurs in the central part of a trough in water depths from 35 to more than 50 fathoms (64 to more than 91 m). It occupies an area about 30 miles long by 10 miles wide (65 × 18 km). The sediment samples taken by us during September 1966 were used chiefly to check that no significant changes in the distribution of sediment types had taken place since Buchanan's survey.

Large numbers of *P. borealis* were taken only from deep water in the area of very fine sand and silt; none was taken from shallower water on fine or medium sand (Fig. 3). The very fine grained sediment was similar to that associated with *P. montagui* at depths of about 5 fathoms (9 m) on the Essex coast[7]. We have found similar sediment associated with *P. jordani* at two localities off the British Columbian coast; in Georgia Strait it occurs at 45 fathoms (82 m) and in Queen Charlotte Sound in 90 fathoms (165 m). Similar sediment is also associated with *P. borealis* at 100 fathoms (183 m) off the coast of Nova Scotia.

Allen[2] reported very low population densities of *P. borealis* in 1955–58 at a point 13 miles east of Blyth. But it was in this same general area that 50 kg/h was taken in September 1966. In March 1967 the work was limited by unfavourable weather, but again in the same general area four hauls of more than 100 kg/h and one of 480 kg/h were made. Although our large otter trawl was more efficient than the small beam trawl used by Allen, there has clearly been a considerable change in the population during the 10 years or so between the two surveys. This is not particularly surprising, because considerable fluctuations can occur in populations with only a small number of year-groups.

It is difficult to estimate the rate of catch which is commercially profitable, because profitability depends on many factors not directly associated with the fishery. A rate of 20 kg/h would probably be worth while[5], and 50 kg/h should give a reasonable profit. Catches of more than 200 kg/h are probably the result of a chance combination of favourable circumstances and it is doubtful if they could be maintained for any length of time.

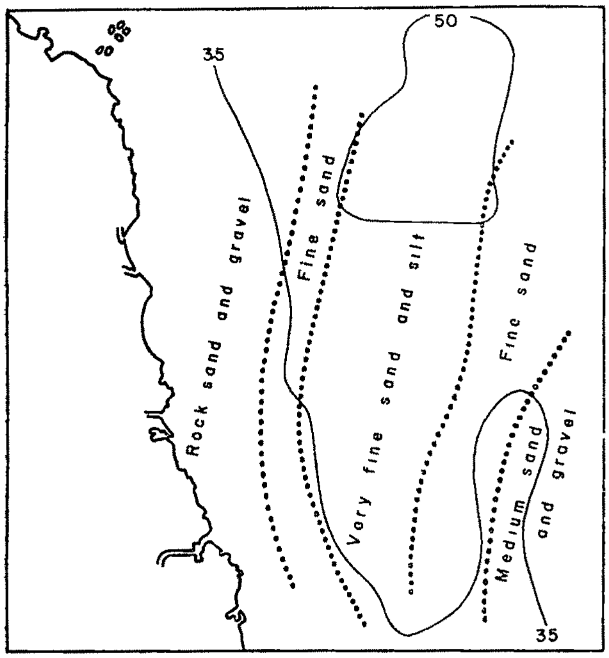

Fig. 2. Sediments off the Northumberland coast (simplified from Buchanan[6]). Depths of 35 and 50 fathoms are also shown.

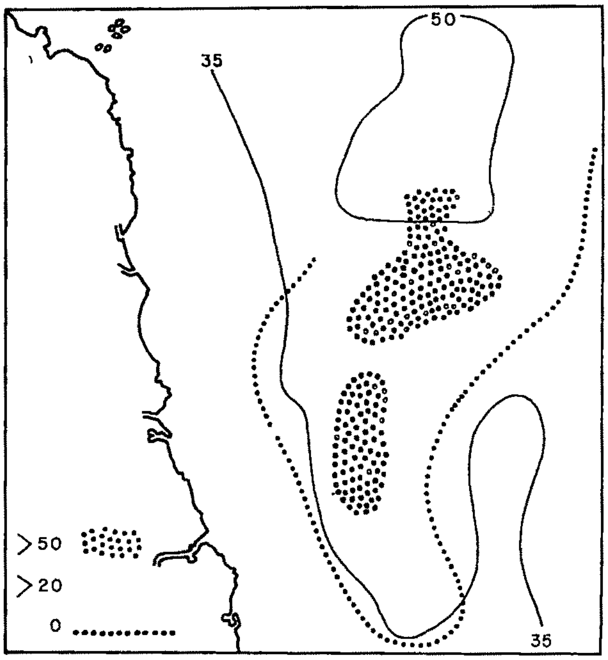

Fig. 3. Catch of *P. borealis* (kg/h). Depths as in Fig. 2.

This area should be able to support a profitable fishery in the years when *P. borealis* is abundant. Boats from various European ports took considerable quantities during the summer of 1967, but as far as we are aware no large catches were landed by British vessels.

Red Light Induction of Gibberellin Synthesis in Leaves

GIBBERELLIC acid is known to mimic the morphogenetic effects of red light[1] on certain plants. Brian[2] has suggested that gibberellins are synthesized in plants after the absorption of red light and Kohler[3] has shown that there is a significant increase in the content of gibberellic acid in etiolated peas after 24 h of irradiation with red light

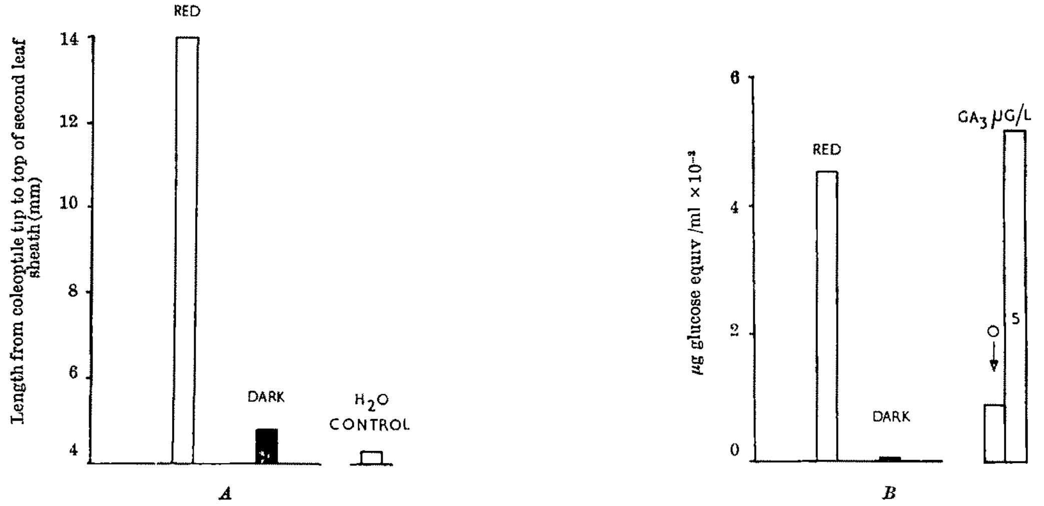

Fig. 1. The effect of red illumination on the gibberellin content of leaves of barley seedlings. *A*, Dwarf-1 maize assay; *B*, barley endosperm assay.

This and other work[4] suggests that phytochrome in the P_{fr} form (after irradiation with red light) initiates synthesis, or at least brings about increases in the content of gibberellin in plants and seeds. Many responses of phytochrome, however, can be observed a few hours (or in some cases in less than 1 h (ref. 5)) after illumination with red light. Thus to explain effects of phytochrome in terms of the action of gibberellin, it is necessary to show that gibberellins are synthesized during or very soon after the end of a period of red irradiation. This is what we have tried to do.

Barley seedlings (variety 'Pallas') were grown in moist sand, in darkness, for 1 week at 25° C. Working in a green safe light[6] a known number of 2 cm segments were cut 1 cm below the leaf tips. These were randomized and placed on moist filter paper and either exposed to red light or kept in darkness. The red source consisted of two 4 ft Atlas red fluorescent tubes and a red 'Plexiglass' filter (Cornelius No. 501). The leaf segments were 80 cm from the tubes. At 660 nm the light intensity received by the segments was 1.38 μW/cm^2.

Extracts were assayed using both the dwarf-1 maize[7] assay and the barley endosperm assay[8]. In the endosperm assay three replicates of each sample were incubated with pieces of endosperm as well as a fourth without endosperm. The blank values were subtracted from the mean sugar values for the other three replicates containing pieces of endosperm.

After receiving the appropriate light treatment leaf segments were homogenized in darkness at a high speed in an MSE top-drive macerator in 10 ml of cold 0.01 molar phosphate buffer (*p*H 7.0) for 5 min. The homogenate was centrifuged at 600*g* for a further 5 min, and the supernatant was adjusted to *p*H 2.5 and extracted three times with ethyl acetate. After separation, the organic fraction was kept at −25° C. The aqueous phase was re-adjusted to *p*H 7.5 and extracted three times with ethyl acetate. This second organic phase was separated from the aqueous layer. The two organic fractions were bulked and evaporated to dryness at 28° C in a vacuum. The solid residue was taken up in buffer (0.01 molar phosphate) with 0.01 per cent 'Tween 20'.

Three hundred leaf segments were irradiated for 40 min with red light, and then returned to darkness and extracted after 30 min. A similar batch of segments was kept in darkness. After extraction half the extract was assayed on the dwarf-maize assay and half on the barley endosperm assay.

Results are shown in Fig. 1*A* and *B*. In both assays the extract from the segments kept in darkness showed no gibberellin-like activity, while that from the segments treated with red light showed considerable activity. This increase of gibberellin activity could be brought about either by release from bound forms[9] or by *de novo* synthesis. Two inhibitors of gibberellin biosynthesis, 2-chloroethyl trimethyl ammonium chloride (CCC) and 2-isopropyl-4-dimethylamino-5-methylphenyl-1-piperidinecarboxylate methyl chloride (AMO 1618), were used to determine whether the gibberellins are synthesized after red light treatment. The inhibitors do not affect the endosperm assay[10]. The segments (200 per treatment) were infiltrated[6] with water, CCC (1 or 10 g/l.) or AMO 1618 (100 mg/l.) before being irradiated with red light.

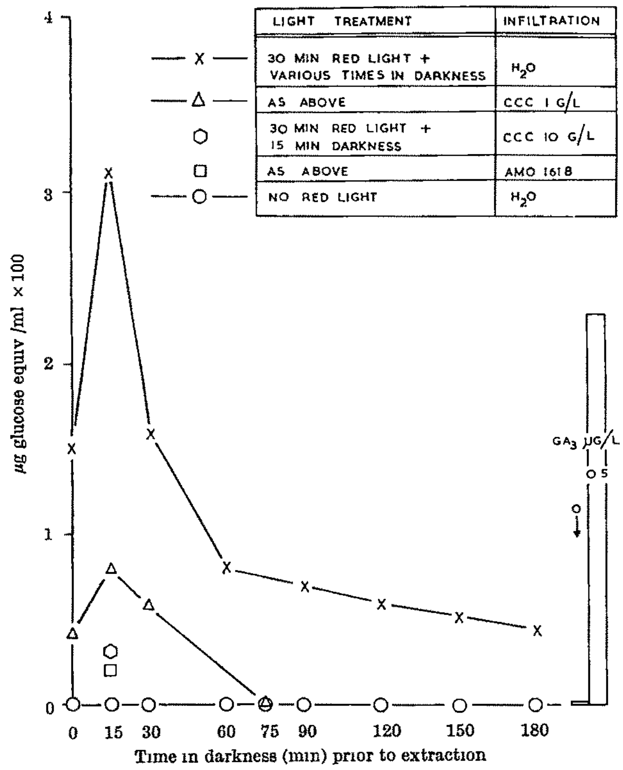

Fig. 2. The effect of CCC and AMO 1618, given before red illumination, on the gibberellin content of leaves of barley seedlings.

After 30 min in red light the leaf tissue was kept for various times in darkness, before homogenization and extraction

The results (Fig 2) show that even immediately after the end of the period of red illumination the leaf segments infiltrated with water contain appreciable amounts of gibberellin activity as compared with dark controls The gibberellin content continues to increase, reaching a maximum within 15 min The level of activity then rapidly falls to a steady low level The transient nature of this peak may explain why many workers have failed to find such an increase of gibberellins after red light treatment The lower curve of the diagram shows the considerable reduction of gibberellin activity when the segments are pre-treated with 1 g/l of CCC This compound, at 10 g/l and AMO at 100 mg/l, almost completely blocks synthesis of gibberellin in the leaf segments These results indicate that the observed rise in gibberellins must be largely a result of a red light-induced synthesis rather than a release of gibberellins from some site of storage

Estimation of the Distribution of Plant Roots in Soil

The difficulty of measuring the distribution of living roots in soil is an obstacle to quantitative studies of the performance of root systems in natural conditions Even the most careful procedures for separating roots from soil are subject to limitations[1] Errors occur especially in estimates of the distribution of the finer lateral roots, which may be of major interest because they can account for a considerable fraction of the total nutrient uptake[2] It is, moreover, often impossible to distinguish living from dead roots An alternative approach to this problem is the injection into plant shoots of radioactive tracers which become reasonably uniformly distributed throughout the root systems Racz *et al* [3] and Halstead and Rennie[4] injected phosphorus-32 into plant shoots and estimated the distribution of living roots from measurements of phosphorus-32 in soil samples The low penetrating power, however, of the beta radiation from phosphorus-32 makes it possible to assay only small soil samples, and the quantities of tracer (for example, 300 μc /plant) which are convenient for measurement[4] can cause the concentration in roots to be within the range which may induce radiation injury[5] A tracer which emits gamma radiation of reasonable energy would have obvious advantages and the use of rubidium-86 was therefore investigated

Preliminary studies in water culture showed that about 10 per cent of the rubidium-86 injected into shoots of barley plants 3 weeks old reached roots in 24 h, the fraction transferred decreased with increasing age, being lower by a factor of about three for plants 8 weeks old Downward movement was similar when 2 μl droplets were injected into leaf sheaths or into the laminae of expanded leaves When plants were grown in well stirred solutions, the quantities of rubidium-86 recovered from the solutions after 3 days did not exceed 10–15 per cent of that in the roots; the loss of rubidium-86 from roots to the soil would thus be a minor source of error over short periods Autoradiographs showed that rubidium-86 was more concentrated in root apices and in the adjoining zones, where cell extension had occurred in the interval between injection and sampling, than in older tissues Because the former tissues, however, accounted for only a small fraction of the total root volume, this lack of uniformity might cause only small errors in assessments of quantities of root in appreciable volumes of soil To examine the distribution of rubidium-86 on this larger scale each tiller of plants grown in water culture was injected, and the root systems were divided into twelve approximately equal samples to simulate as nearly as possible the roots which might be present in different zones of soil The coefficient of variability of measurements of activity per unit fresh weight was 20 per cent or less In view of the errors of other methods for measuring root distribution the agreement was considered sufficient to justify experiments in the soil

Because of the variability in root distribution in the field, it was desirable to assay relatively large soil samples, a method developed for surveys of environmental radioactivity enabled samples 2 5 to 3 kg in weight to be handled[6] After thorough mixing, the soil was packed into cylindrical polythene containers of 17 cm internal diameter and 17 cm deep, re-entrant cavities 7 5 cm deep in the bases of the containers enabled them to be fitted over the stainless steel housing of a sodium iodide scintillation crystal activated with thallium (nominal dimension of crystal, 3 × 3 in) A multi-channel pulse height analyser was used to reduce the sample background When the same sample was re-packed, the reproducibility was about 3 per cent and 1 μc of rubidium-86 distributed throughout a sample gave about 2,300 c p m ; separate calibrations were made for each soil

To facilitate examination of sampling and analytical errors in the preliminary experiments, it was necessary to have a relatively uniform distribution of roots Barley plants were therefore grown in well mixed soil contained in boxes approximately 0 5 m^2 in surface area Plant rows were 15 cm apart Seven weeks after sowing, when the fifth leaf on the main axis had developed, two injections of 6 μc of rubidium-86 were made into every plant, the injected tissues were removed after 24 h Soil cores 4 5 cm in diameter were taken and divided into sections 5 cm long, and fifteen of the segments were combined to provide a sample for analysis from each depth Duplicate samples of this type were made within the plant rows in each box, alternate cores being assigned to each replicate; similar samples were taken mid-way between the rows. The mean results for four such boxes are shown in Table 1, the values for the different depths being expressed as percentages of that in the surface horizon within the rows, where root development was greatest, the counting rates of samples from this zone averaged 3 5 × 10^3 c p m above background The standard errors reflect differences between boxes and between replicates in the same box;

Table 1 ESTIMATES OF THE DISTRIBUTION IN SOIL OF THE ROOTS OF BARLEY PLANTS 7 WEEKS OLD GROWN IN ROWS 15 CM APART

Soil horizon (cm from surface)	Within plant rows	Mid-way between plant rows
0–5	100	7 4±2 1
5–10	14 1±2 6	5 8±0 8
10–15	5 4±0 4	4 0±0 6
15–20	4 3±0 7	2 8±0 5
20–25	4 7±0 8	3 1±0 4
>25	7 0±1 1	6 3±0 9

Standard errors based on eight observations are shown

Results expressed as percentages of the value for the surface horizon within the plant rows the former errors were shown to be responsible for over two-thirds of the total error Because considerably greater variability must usually be expected between field plots, it is to be expected that the procedure for subdividing and assaying soil cores will be a minor source of experimental error in field investigations

The applicability of the procedure to other types of plants will depend both on the extent to which the tracer is translocated to roots and on the uniformity of its distribution within them Perennial woody species may present special problems and the type of information sought in any study may influence the degree of variability in the distribution of the tracer throughout the root system which can be tolerated It should be possible, for example, to demonstrate whether changes in agronomic practice alter the distribution of living roots—often a question of major interest—even if variations in the activity of tracer per unit weight of roots cause uncertainty in estimates of the actual amounts of root present at different depths

APPLIED SCIENCE

Difference in Flight Capacity between Naturally Occurring Spring and Summer Forms of *Myzus persicae* (Sulz.) (Hemiptera:Aphididae)

One approach to the problem of the distances flown by aphids is to study the length of time they retain the ability to fly In many species, flight capacity is restricted to the first few days of adult life, and this has important implications for the epidemiology of plant viruses and, in particular, viruses of the "persistent" type, such as potato leaf roll virus Alate "alienicolae" of *Myzus persicae*, in common with several aphids of economic importance, lose the ability to fly about 3 days after the final moult, provided they settle down on a host plant, for settling is a prerequisite for the physiological processes leading to flight muscle autolysis[1–3].

In order to acquire sufficient potato leaf roll virus to infect a second plant, initially uninfected aphids must settle and feed for several hours on an infected source plant Smith[4] showed that the virus is not acquired by *M. persicae* until it has fed for at least 6 h on an infected potato plant, and Kassanis[5] confirmed this From Johnson's work[1–3] it might be expected that spring migrant *M. persicae* which fly to the potato crop from the primary host plants (*Prunus* species) would not take flight again after they have settled long enough to acquire the leaf roll virus In England, however, most potato leaf roll spreads usually early in the year when spring migrants of *M persicae* are entering the crops[6,7] These spring migrants include both alate "fundatrigeniae"—the first winged progeny of the parthenogenetic generations derived from the fertilized eggs laid on the primary host—and alate "alienicolae", winged parthenogenetic aphids produced in the spring by a stock of parthenogenetic aphids overwintering on secondary hosts.

The relative importance of alatae and apterae in the spread of leaf roll and other persistent viruses is still controversial[8], and Ribbands[9] attributed the early spread of leaf roll to the apterous progeny of alatae which had settled on infected potato plants These alatae might be either alate "fundatrigeniae" or alate "alienicolae", and it is possible that different forms of the same species vary in their biology, either intrinsically or because of differences in the conditions in which they were reared

Small branches of peach, bearing masses of fourth instar alate nymphs, were cut from trees growing in the garden of the Entomological Field Station, Storey's Way, Cambridge The branches were placed in jars of water in a large cage standing in a dark constant-temperature room at 21° C Many of the nymphs moulted to adult during the night, and many of these alate "fundatrigeniae" took off within a few minutes when an overhead 400 W mercury vapour lamp was switched on in the morning Alate "alienicolae" were collected at the same time in a similar way, by bringing into the constant-temperature room sprouting mangolds from a clamp in Cambridgeshire heavily infested with *M persicae*

The "fundatrigeniae" required a much longer bout of flight time than the "alienicolae" before they would settle on potato leaves Alatae which had just completed their teneral development were flown in groups in the flight chamber described by Kennedy and Booth[10] After the flight each aphid was placed on to a young detached leaf of potato, variety 'Majestic' The leaves were kept in tubes of water for 24 h in the dark in the constant-temperature room at 21° C, and then put into a "non-return box"[10] and illuminated by a 40 W "daylight" fluorescent lamp for 1 h Table 1 shows the number of aphids remaining settled on the leaves after 24 h in the dark and after a further hour in the light

The flight capacity of the "fundatrigeniae" and the "alienicolae" was compared by flying batches of newly flight-mature alatae in the flight chamber for at least 5 h to promote settling Aphids were kept on young 'Majestic' potato plants in cages in the laboratory at room temperature (20° C) They were gently removed from the plants each morning with a fine paint brush and kept in glass tubes for 1 h in a brightly illuminated flight-testing chamber To test their ability to fly they were dropped from a paint brush held about 75 cm above the floor[3] A maximum of ten tests per aphid was made Fig 1 shows only those aphids which ceased to fall and began to gain height on being dropped The "fundatrigeniae" retained the ability to fly for an average of 3 61 days, the "alienicolae" retained the ability to fly for an average of 2 36 days The difference is significant at $P < 0\ 001$

While it is evident that there were significant differences in the flight behaviour of the two forms of aphid compared in these experiments, it should be noted that the aphids came from only two samples and that equally large differences in flight behaviour might well be found within alatae of either form from different sources Nevertheless, both groups of aphids came from naturally occurring populations of *M persicae* found in the field at the normal time

Table 1 NUMBERS OF FUNDATRIGENIAE AND VIRGINOPARAE REMAINING SETTLED ON POTATO LEAVES AFTER FLIGHTS OF 1 AND 5 H

	Flight duration					
	1 h			5 h		
		No settled			No settled	
	No flown	After 24 h in dark	After 1 additional h, in light	No flown	After 24 h in dark	After 1 additional h, in light
Fundatrigeniae	40	22*	12†	12	12	8‡
Virginoparae	30	26*	20†	15	15	15‡

* Significant at 5 per cent $\chi^2 = 6\ 57$
† Significant at 1 per cent $\chi^2 = 7\ 87$
‡ Significant at 1 per cent $\chi^2 = 5\ 869$

of year Alate "fundatrigeniae" were collected from several peach trees and alate "alienicolae" were collected from many sprouting mangold roots Furthermore, a difference in the same sense was reported by Ronnebeck[11], who concluded that *M persicae* from peach trees ("fundatrigeniae") flew farther in the field than did alate "alienicolae" from stocks overwintering on savoy cabbage seed crops

It therefore seems likely that many alate "fundatrigeniae" entering the potato crop in early summer remain flight-worthy long enough to spread even a persistent virus like leaf roll if they feed for sufficient time on infected plants during the first few days after their migratory flight Moreover, their flight capacity is greater in the cool temperatures prevailing at this time of the year, for in experiments carried out in this laboratory, alate "fundatrigeniae" kept at 15° C retained the ability to fly for more than twice as long as alate "fundatrigeniae" kept at 25° C

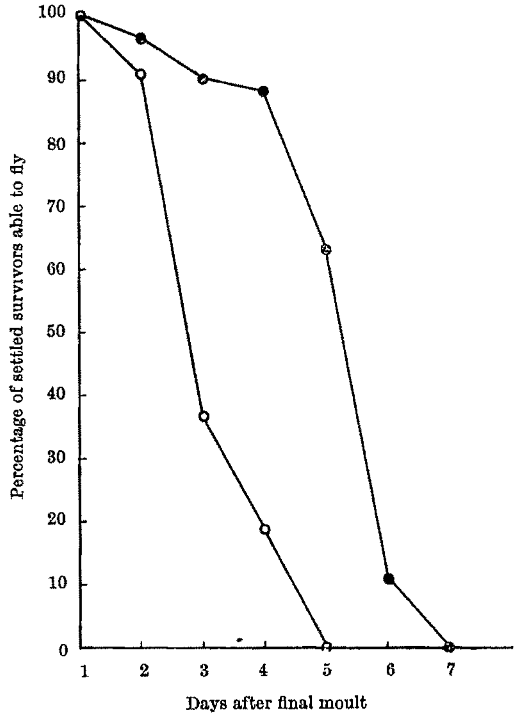

Fig 1 Flight-worthiness of alatae after an initial flight of 5 h ●, Fundatrigeniae, n = 110, ○, virginoparae, n = 22

This work was started under the supervision of the late Dr C R Ribbands, for whose encouragement I am grateful I thank Dr J S Kennedy for advice and discussion, Professor Sir Joseph Hutchinson for providing facilities, and the Agricultural Research Council for a grant

GENERAL

Holographic Model of Temporal Recall

Professor Longuet-Higgins[1] has called attention to the remarkable property of human memory of recognizing and recalling long sequences of which at first only a small fraction is consciously remembered, and he has devised a most interesting, physically realizable mathematical model which achieves just this He has rightly called this a temporal analogue of holography I wish to show that there is at least one other mathematical model, which I consider to be a closer analogue of holography, because it operates with triple products of the temporal function to be recognized or recalled

Let the signal $A(\tau)$ start at $\tau = 0$ At the time t_1 we record the convolution integral

$$\varphi(t_1) = \int_0^{t_1} A(\tau)A(t_1 - \tau)\mathrm{d}\tau \quad 0 < t_1 < T$$

where T is the total duration of the signal In order to recognize or to recall the signal we take $\varphi(t_1)$ from the store and form a convolution integral with a signal A' which need be only a fraction of the longer sequence A The recalled function is

$$R(t) = \int_t^T A'(t_1 - t)\varphi(t_1)\mathrm{d}t_1 = \int_t^T A'(t_1 - t)\mathrm{d}t_1 \int_0^{t_1} A(\tau)A(t_1 - \tau)\mathrm{d}\tau$$

Reversing the order of integration in the trapezoidal region $t < t_1 < T$, $0 < \tau < t_1$, we obtain

$$R(t) = \int_0^t A(\tau)\mathrm{d}\tau \int_t^T A'(t_1 - t)A(t_1 - \tau)\mathrm{d}t_1 + \int_t^T A(\tau)\mathrm{d}\tau \int_\tau^T A'(t_1 - t)A(t_1 - \tau)\mathrm{d}t_1$$

If now the function A is one which correlates sharply with itself, that is, if it is as often positive as negative and not regular-periodic, the two factors of $A(\tau)$ under the integral signs will be of the nature of delta-factors, $\delta(\tau - t)$, which become noticeably different from zero only for $\tau = t$, so that

$$R(t) \propto A(t)$$

with more or less "noise" if A' is only a fraction of A

This is therefore a possible mechanism for recall It is also a mechanism for association It is easy to see that, if we replace $A(\tau)$ by some other function $B(\tau)$ and record its convolution with $A(\tau)$, we shall be able to recall B by means of A or a part A' of it

The process can also be digitalized The functions A, B can be discrete sequences of $+1$ and -1, or of "yesses or noes", defined only for certain points of time, and the integrals are then replaced by sums over the lattice points in the trapezoidal area This makes the model realizable with "McCulloch–Pitts neurons" The best procedure would be probably to record first $A(\tau)$ in a first store, and then transfer it to a second store, where it is multiplied with itself, back-to-front, one multiplicand starting at $\tau = 0$ and the other, backwards, at $\tau = t_1$ The signal A could then be recalled, by a similar operation in a third, "associative" organ, by a fraction A' of itself, or by any other sequence which has a part (such as a word, or several words) in common with it

I do not wish to suggest, of course, that this model corresponds any more closely to the reality of the nervous system than Longuet-Higgins's system of resonators

BOOK REVIEWS

TOP BIOLOGISTS

Nobel Lectures

Physiology and Medicine 1901–1921, including Presentation Speeches and Laureates' Biographies. Pp. xii + 561. (Amsterdam, London and New York: Elsevier Publishing Company, 1967. Published for the Nobel Foundation.) 180*s*.

THE Nobel Foundation has arranged for the publication, in English, of the Nobel Lectures in the various subjects (physics, chemistry and so on). This volume contains the lectures in physiology and medicine for 1901–21. In trying to make overall judgments about this series of statements one is handicapped by their small number, which gives any generalizations small statistical reliability, especially because the authors and their subjects are very varied. It would perhaps have been better to review all the lectures in one subject when they have been published. This would involve reading three times more of them and the strain of following the great thoughts of so many great men might lead to disillusionment.

As it is, however, the volume is a pleasure and a stimulus. Many thoughts occur as one reads, mainly thoughts of admiration. The staff of professors of the Royal Caroline Institute have done their work well. There is nothing here that is silly, very little that is wrong and an enormous amount that was highly original in its day and is still interesting now. Only one prize was awarded for work that turned out to be of quite minor scientific and clinical importance (that of Finsen in 1903 for phototherapy of *Lupus*, and he gave no address). But what a galaxy of success there is, Ross and Laveran, Koch and Pavlov, Golgi and Cajal, Metchnikoff, Ehrlich and Krogh, Kossel and Carrel. Of course, such a selection cannot always be exactly right. The electors have had their quirks, such as choosing Ross five years before Laveran, and pairing off Golgi and Cajal together, in spite of their disagreements and dislikes. But such differences of personal and scientific style are with us still. To see the lucky ones ill-matched together at least gives sardonic amusement to the less fortunate.

It would not be easy to make a convincing analysis of the success of these biologists and medical scientists. But some general points emerge. The unity of biological and medical science stands out on almost every page. Some assert it openly as Metchnikoff: "To solve medical problems comparative pathology had to be brought in". In his case it involved the study of the larvae of starfishes and it was with these that the phenomena of inflammation and phagocytosis were revealed, to be confirmed later by work on water fleas!

Nearly all of these prize-winners used and refer to animal experiments at the very centre of their work, some without being theoretical about it, others like Pavlov, meditating on the necessity to "ignore the mental state of the animal". Having revealed how "four simultaneously acting lethal causes were deliberately eliminated" he comments: "A striking proof of the power of science that regards the organism as a machine", a power we still need as much as ever today, but are often too mealy-mouthed and frightened of conventional views to admit it.

Of course, the awarders of the prizes have not been unheedful of the importance of the practical clinical results of medical research. We cannot, therefore, use the lectures to estimate how far investigators work with practical ends in view. But the awarders carefully avoided over-attention to this aspect and it is interesting that those of their choices who gave least attention to immediate practice were conspicuously the more influential and also in the end produced the greatest effects. The surgeon Kocher no doubt did a great deal for our understanding of the pathology of the thyroid and his address is an interesting account of it, but it is incomparably less important than the entirely academic presentations such as that by Cajal on neurones or by Kossel on the nucleic acids, protein and histones of the nucleus. Again both of these two chose material from all over the animal kingdom. Kossel took histones from the red cells of birds and the sperm of sea urchins and cephalopods and protamines from the milt of fishes. What a lot he knew about the nucleus even in 1910.

Indeed it is inspiring, if humbling, to see the width of knowledge, experience and indeed wisdom shown by most of these men. Of course they wrote their addresses carefully, but also in something of a hurry. The products must reflect their natural capacities and tastes, and these are mostly admirable. Many of the Nobel Prize-winners write well, often personally, but with respect for their predecessors and contemporaries, and seldom rancour over the opposition which many of them encountered. Final reflections: no single address in twenty years contains a mathematical formula, and only Ross, Cajal and Golgi felt the need for any great amount of illustration. Even considering the formal nature of the occasions of presentation these are curious features of the addresses delivered by the greatest ones of physiology and medicine (1901–21). J. Z. YOUNG

BRAIN–HORMONE INTERACTIONS

Neuroendocrinology

Vol. 2. Edited by Lucian Martini and William F. Ganong. Pp. xix + 777. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 256*s*.

THE first of the two volumes of this treatise on neuroendocrinology dealt mainly with the anatomy of the hypothalamo-pituitary system in mammals, methodology, and the classic problem of the neural control of the secretion of the anterior and posterior pituitary hormones. It was reviewed (*Nature*, 215, 448, 1967) as an addition to the literature of a rather specialized area of research that was already extensively covered by other reviews, monographs and reports of symposia. Considerable duplication was inevitable and, although some excellent chapters were noted, the book as a whole was not considered to offer a great deal of material that was not already fairly easily available elsewhere to a reader reasonably familiar with the field. The same cannot be said of the second volume, for the editors, Ganong and Martini, have now made available a more extensive and complete survey of neuroendocrine topics than has been attempted previously in a single work.

The overall plan seems to have been to assign a general field, rather than a limited topic, to contributors actively engaged in a wide range of biological research. On the one hand this approach has resulted in an expert compilation and sifting of scattered results from many sources that are relevant to neuroendocrine investigations, while on the other hand those workers concerned with varied aspects of a particular problem have been able to present their specialized knowledge in a coherent form for the general reader. Contributions of the first type include a chapter by Gold and Ganong on the effects of drugs on neuroendocrine processes, a critical review by Ganong and Lorenzen on brain neurohumours and endocrine function, and discussions of invertebrate and lower vertebrate neuroendocrinology by Hagadorn and by

Jørgensen and Larsen Specific problems discussed in depth include the control of the onset of puberty (Critchlow and Bar-Sela), the effects of light on endocrine function (Wurtman), and control of the pars intermedia (Etkin)

The action of hormones on the central nervous system is also discussed in detail in this volume Barraclough reviews the long-term effects of pre-natal and post-natal exposure of the brain to abnormal gonadal steroid levels on reproductive function, one of the most exciting areas of neuroendocrine research in the last decade The specific effects of gonadal steroids in eliciting sexual behaviour and the influence of these and other hormones on brain excitability in general receive comprehensive treatment from other contributors The "feedback" action of the target organ hormones on the hypothalamus or pituitary to modify trophic hormone secretion was dealt with in the earlier volume Indeed, there are few topics that could reasonably be included under the heading of "Neuroendocrinology" that have escaped notice in one or other volume although the higher mental functions are perhaps one No discussion of the studies of the acute and chronic effects of hormones on conditioned aversive behaviour in animals was noted, nor was there any attempt to review the extensive, though often contradictory, literature on the possible role of endocrine factors in psychiatric disorders in man

Although this second volume covers such a diversity of topics, the overall impression is not one of discontinuity On the contrary, the juxtaposition of findings from so many branches of biology serves to emphasize the relevance of data from other fields to the specialist's understanding of the significance of brain–hormone interactions in his own area of interest The high standards of editing and production achieved in the first volume have been maintained in this second volume, together they provide a valuable source of factual information for the endocrinologist in search of details and a very complete presentation of current views and interests in the field of brain–hormone interrelations for the biologist who is not himself involved in such studies but needs an overall view of the activities of his contemporaries in this area of research

K BROWN-GRANT

FROM MIND TO MIND

The Psychology of Human Communication

By John Parry Pp 248 (London University of London Press, Ltd, 1967) 30*s*.

"COMMUNICATION is all", a twentieth century Keats might say, surveying the triumphs of communication theory in the sciences and the arts, for all of which it makes bold to offer a new Esperanto Psychologists too have profited from this general enrichment of the world of learning by the acquisition of novel tools of conceptual analysis, but they have been apt to regard the idea of communication they that of information) as too sacred to tamper with In the result, communication theory has sometimes turned out to be a Procrustean bed for psychological phenomena, since a blind eye has been turned to the purely human facts of communication to which models must be fitted

Hence the task Dr Parry has set himself He has endeavoured to convey to the reader the distinctive and sometimes imponderable character of the psychological phenomena in the domain of communication, and to consider the types of message one individual wishes to transmit to another, the barriers that prevent or distort transmission, and the lines of research relevant to these problems.

In the first part of this book he deals with various types of information among which he distinguishes human from artificial systems. He then proceeds to discuss the role of language as a medium and of feeling as a message, compares scientific with artistic expression, and differentiates between "sign" and "content" information, categories which are perhaps more familiarly known as "selective" and "semantic", respectively

The second part is devoted to an exposition of barriers to communication Seven are described, they are limitation of the receiver's channel capacity, distraction, unstated assumptions, incompatible schemas, unconscious pressures, poor presentation, and absence of channels The third part moves on to examine problems of communication in complex activities such as personnel selection and the administration of the law, and finally, in the fourth part, Dr Parry presents his theme as a branch of research

Dr Parry is clearly well versed in the literature Nevertheless, there are significant omissions which, if reference had been made to them, would have strengthened his thesis There is no mention, for example, of the epidemiological model which L S Penrose and others have used in a variety of contexts of human communication, in particular, where ideas are disseminated throughout a group.

While the treatment on the whole is reasonably critical, there are occasional lapses Thus a chapter is given to ten instances of failure in communication at the end of which we are told the "likely reasons" for the failure in each case. But these reasons are not very illuminating Thus case 4 is "A father and son are at odds. Each says that the other refuses to consider his point of view" The "likely reason" is "schema incompatibility" Are we now much wiser ? Dr Parry defines a "schema" as "an enduring pattern of brain activity", but unless we know something about this pattern what do we achieve by giving it a name ? Dr Parry might have heeded a warning given by Professor R C Oldfield that the word "schema" has an important role in contemporary psychology because "it stands for something of which we are ignorant"

It is also surprising not to find any mention of communication in committees and conferences, or to the technique of "role reversal" which several investigators have fruitfully employed

Nor is there any mention of recent experiments on subjective scaling of selective or sign information which would have been germane to his theme, and, while he realizes that selective information is not the whole story, there remains much more to be said about the scope and nature of subjective (semantic, content) information.

It is doubtful whether, in the fourth part of the book, Dr Parry has succeeded in conveying the gist of relevant research to readers unfamiliar with the original sources And the abstracts are presented in a sequence which does not bring out any coherence, if any they possess.

Nevertheless, in spite of these shortcomings, the volume as a whole is a timely and salutary corrective to the dehumanization of communication theory in contemporary psychology

JOHN COHEN

LAYMAN'S ACADEMIC PSYCHOLOGY

Psychology and Social Problems

By Michael Argyle Pp 232 (London Social Science Paperbacks in association with Methuen and Co, Ltd, 1967) 16*s* net

IT is difficult to project a book primarily at the layman while maintaining interest and precision and academic respectability Such a book may well end as a mass of fascinating but unwarranted generalizations or, at the other extreme, as an uninteresting list of experimental findings which are thought to be of particular everyday relevance In his *Psychology and Social Problems*, Mr Argyle neatly avoids either of these poles He has produced an easily readable book which deals with topics of social importance in an acceptable academic manner The chapter headings read like a list of problem areas, on which (often to his embarrassment) the professional psychologist is frequently asked to pontificate by chance acquaintances. Argyle deals with these topics in an authoritative manner, making few statements which he cannot support with sound scientific evidence.

Consequently, I feel that this book is useful at two levels. First, as a direct fund of information to the layman, and second, as a source book for the psychologist who wishes to answer the questions of the layman but whose specialized interests lie in other areas of behaviour.

At a more particular level, Argyle is especially lucid in his discussions of interpersonal relationships, crime, mental health and racial prejudice. In my estimation, however, he does not fare as well when considering child rearing and the motivation of social behaviour. Here, it can be argued, he places too little emphasis on that body of research and thought which offers the most promising approach, that is, that stemming from learning theory. Further, I would criticize the book with respect to the arrangement of its references. It is frustrating to have to turn continually to the final section of the book in order to check these. These criticisms, however, are somewhat trivial and detract very little from what is basically a well-written and useful book.

Finally, it is interesting to note Argyle's observations on measures which would help to reform various undesirable social conditions. They are a mixture of enlightened common sense and suggestions springing directly from research. One has the impression that they would satisfy the final analysis demanded by society—they would work.

K. T. STRONGMAN

DATA TO THEORY IN SOCIAL SCIENCE

Theory and Methods of Social Research

By Johan Galtung. Pp. 534. (Oslo: Universitetsforlaget; London: George Allen and Unwin, Ltd., New York: Columbia University Press, 1967.) 70*s* net.

THIS thought-provoking treatise is, as its author says, "neither an introduction nor a handbook" to social research methodology. "Rather," he explains, "the intention has been to try to integrate things usually kept apart: techniques of data collection, techniques of analysis, statistical methods, and some philosophy of science." The result is a unique and stimulating work, in the tradition of Lazarsfeld and Hyman, but with an added breadth and comprehensiveness. For all but a few British sociologists at the present time, the mathematical treatment is likely to prove difficult, but no one seriously interested in social research method can fail to derive benefit from the book as a whole.

The unifying concept is the data matrix, the tripartite structure into which all social science data can be fitted, consisting firstly of elements or units of analysis, secondly of dimensions or variables and thirdly of the values of the units on the variables studied. The first part of the book deals with data collection, the second part with data analysis. Developing the logic of the data matrix, there are chapters on the units (and problems of sampling), on the variables (and levels of measurement) and on the values (with the arguments for and against rating or ranking them). There follow sections on the main forms of data collection and on surveys. This second part subdivides into three, beginning with data processing, statistical distributions, patterns and indices, continuing with a discussion of hypotheses and their "dimensions" and methods of multi-variate analysis, and concluding with a chapter on the logic of theory formation.

So bare a summary cannot convey the book's rich content. While some tools of analysis discussed are "close to or beyond the limit of what contemporary social science can digest", no method, however humble, is taken for granted. We are made to think through each mental operation afresh and emerge with our logical muscles considerably and no doubt beneficially stretched. The author's combination of reasoning power and pragmatic awareness of the social science research context is unusual and impressive.

Classical statistics from Galton to Fisher largely assumed interval scale variables and normally distributed universes. The publication of Siegel's *Non-parametric Statistics for the Behavioral Sciences* in 1956 opened up ampler perspectives. But much is still missing. "The field of ordinal scale statistics is in wild disorder" and this is by far the most important field for the social scientist, who typically can develop ordinal measures but rarely interval scale measures. "What social science analysis lacks most at the moment is a language, in which *degrees* of correlations can be expressed; a language which is stronger than ordinary prose, yet weaker than interval scale mathematics of functional relationships."

Looking perhaps yet further ahead, he calls for a development of the language of process. There is no simple relation between this language and that of correlation, nor can one in general infer from synchronic to diachronic correlation or vice versa. Therefore there should be much more emphasis on longitudinal data in social science, and much less on the synchronic type of study. Social theory should be presented in the process language as a set of variables related by one-way or two-way, negative or positive processes. The pragmatic concept of process is preferable to the dogmatic concept of cause and effect. Processes are difficult to study because of the time they take to unfold, but a variety of methods are suggested, including a combination of historical source data with modern sampling methods and the analytic machinery of content analysis.

The book is well produced, with an exceptionally beautiful jacket, on the back of which we read that our author was born in 1930, holds degrees in both mathematics and sociology (Oslo, 1956, 1957), taught at Columbia University, 1958–1960, and was Unesco Professor of Sociology at Santiago, 1962–63 and 1965. Since 1959, he has been the Director of the International Peace Research Institute, Oslo.

C. MADGE

PHYSICAL CHEMISTRY OF PIGMENTS

Pigments

An Introduction to their Physical Chemistry. Edited by David Patterson. Pp. xii+210. (Amsterdam, London and New York: Elsevier Publishing Company, Ltd., 1967.) 65*s*.

THE scarcity of reliable and really informative scientific books on the subject of inorganic and organic pigments is the cause of great difficulty to those who are students or teach in this field. The organic or inorganic chemistry of pigments is in general fairly straightforward even though it is often cloaked by industrial secrecy. The difference between a coloured insoluble compound and a pigment, however, is as great as that between carbon black and a diamond, and sometimes more costly to achieve. It is the study of the properties of pigments which make them useful as distinct from simple coloured matter which constitutes the subject of the physical chemistry of pigments. In this field we must be concerned with molecular phenomena such as electromagnetic absorption, optical dispersion and photoexcitation, and with particular phenomena including crystal structure, nucleation, particle size and surface properties. Additionally important techniques must be considered, notably colour measurement and computation, and particle size analysis.

In July 1964 a summer school was organized under the auspices of the department of colour chemistry at the

University of Leeds on the topic "Progress in the Chemistry and Technology of Pigments" which covered the physical chemistry of pigments Dr Patterson has taken the proceedings of the school as a basis and with additional material has compiled the first available book on the topic. Normally summer school proceedings do not provide a sufficiently coherent body of information to make a readable book, but the policy of combining a chapter on some aspect of general theory with another on the application of the theory to pigment problems has avoided the dangers most effectively The text still betrays its spoken origins For example, there is the occasional "verbless sentence" This tends, however, to maintain a brisk informal style which carries the reader forward

Five of the ten chapters are concerned with colour Theories of colour of inorganic and organic molecules are considered in the first two chapters In dealing with organic molecules very great emphasis is placed on the free electron method of calculating light absorption with perhaps too little attention paid to molecular orbital and valence bond methods One chapter is concerned with the colour of organic crystals with interesting information about orientation effects on light absorption mechanisms Two further chapters on colour are concerned with instrumental methods of colour measurement and colour match prediction, respectively The particular aspects of pigments are considered in four chapters concerned with nucleation and growth of particles, particle size measurement, surface activity and theories of dispersion, flocculation and flotation Photoexcitation in pigment crystals is considered in relation to the question of photoconduction and the degradation of organic molecules This chapter is accommodated less easily than the others, but the editor's contention that photoconduction studies in this field are of special relevance to the question of the light fastness of pigments is well supported

This book succeeds in what it sets out to do, namely, to indicate in some detail the scope of a far ranging subject It will prove of great value to students or research workers coming fresh to pigment problems, providing a guide to their further education. I D RATTEE

REFERENCE TO PLUTONIUM

Plutonium Handbook

A Guide to the Technology Vol 1. Edited by O J Wick Pp x+520 (New York and London· Gordon and Breach, 1967) $26

THE aims of the two volumes of this work are stated as being the provision of information on a wide range of topics concerned in the utilization of plutonium and of a first reference on its technology In view of the progressive relaxation of classification restrictions since the first limited release of information on the properties of plutonium in the United States and Britain in 1954, these objectives constitute a very considerable task The editor is therefore to be congratulated on producing a first volume of manageable proportions which covers the physics, metallurgy and chemistry of the metal and its compounds The sub-title of the work, "A Guide to the Technology", seems inappropriate for the first volume, although a preview of the chapter titles for the second volume suggests that it may be more applicable to the latter

The individual chapters have been written by acknowledged experts in the appropriate fields from a number of American atomic energy laboratories Not unexpectedly, major contributions have been made by the Los Alamos and former Hanford, now Pacific North West, Laboratories Clearly it has taken a considerable time to bring together all the individual contributions into a single volume and the most recent references quoted are dated 1965 In particular, no reference is made to any of the papers presented at the Third International Conference on Plutonium held in London in November 1965 Some qualification must be made, therefore, about using the work as a first reference Within individual chapters the authors have attempted to incorporate references to work throughout the world, though naturally there is a preponderance of American references in view of the large proportion of the work which has been done in that country The chapter lengths are very uneven and a more balanced result might have been achieved if subjects of equal weight had been chosen for each chapter Minor chapters such as "Metallography" and "Laboratory Techniques" might well have been combined or even omitted There is also some overlap between different chapters which could have been cut out without great loss, for example, data on the Pu–O and Pu–C systems The author index and subject index are only to be published with the second volume which provides a slight limitation on the value of the first volume alone Having made these criticisms, however, it must be said that the principal chapters are in general excellent, both in technical content and in readability

The book will undoubtedly find use in all plutonium laboratories as a compilation of the principal features of the chemistry and metallurgy of plutonium and its compounds, although the combined price of the two volumes is likely to be rather prohibitive for individual purchasers.

P G MARDON

TWENTY YEARS ON

Dynamic Aspects of Biochemistry

By Ernest Baldwin Fifth edition Pp xiv+466 (London Cambridge University Press, 1967) 55s net, $9 50

IT says much for the original dynamism of Professor Baldwin's book that it reappears now in its fifth edition some twenty years after it first burst on the biochemical scene The two previous editions had given the impression that the book was beginning to lose ground a little in the rapid advance of the subject It was to be hoped that this would be redressed in a new edition, which has been reset in a larger format and for which, it is claimed a major revision has been made It is a great disappointment to have to report that these hopes are largely in vain. Two chapters, those on protein biosynthesis and fat metabolism, have indeed been completely rewritten and another, on special aspects of nitrogen metabolism, has been dismantled, but much remains which is now outdated For example, it detracts much from the value of the book to read speculations concerning the position of the extra phosphate group in NADP$^+$, or again those about the origin of deoxyribose, which take no account of Reicherd's work on reduction at nucleotide level Even worse is the misstatement concerning the localization in the cell of the iso-citrate dehydrogenases and there are erroneous formulae such as those for active methionine and ubiquinone which have been transferred uncorrected from the fourth edition

The chief criticism of the book, however, must be its failure to deal with important new developments in biochemistry One could list such topics as isoenzymes, allosterism and the relationship between structure and function in enzymes as exemplified by ribonuclease and lysozyme

The opportunity has been missed to revitalize *Dynamic Aspects* to meet the demanding requirements of the honours student who has, nowadays, a number of excellent modern texts available To those, however, approaching biochemistry for the first time and for whom a complete and balanced up to date coverage is not a requirement, then *Dynamic Aspects* may well be recommended C A ROSS

University News :

Cornell

Dr Carl Sagan, assistant professor of astronomy at Harvard University, has been appointed an associate professor in the Department of Astronomy

London

Mr R N Pryor, general manager of the Rio Tinto Patino SA, has been appointed to the chair of mining tenable at the Imperial College of Science and Technology

Manchester

Mr Peter Dovell, at present head of the Birmingham School of Planning and Landscape, has been appointed to a newly established chair of urban design.

Announcements

The Council of the Geological Society of London has made the following awards for 1968 Wollaston Medal to Professor R C Moore, Lyell Medal to Mr M Black, Murchison Medal to Dr G Wilson, Wollaston Fund to Dr S Moorbath; Murchison Fund to Mr R K Harrison, a moiety of the Lyell Fund to Dr R G C Bathurst, another moiety of the Lyell Fund to Mr R E Elliott

The Institute of Metals has made the following awards Institute of Metals (Platinum) Medal for 1968 to Dr W J Kroll in recognition of his services to the non-ferrous metal industries, Rosenhain Medal for 1968 to Dr D W Pashley in recognition of his contributions in the field of physical metallurgy; W H. A. Robertson Medal for 1967 to Mr T Z Blazynski for his paper, "An Assessment of a Combined Rotary Piercing and Elongating Process for Tube Making", published in the *Journal of the Institute of Metals*, April 1967

Meetings

Tenth Anniversary Meeting of the Phytochemical Society, April 1–3, University of Cambridge (Dr J B Harborne, Hartley Botanical Laboratories, The University, Liverpool 3)

Properties and Metrology of Surfaces, April 1–4, Oxford (Mr R S Glynn, Conference Department, The Institution of Mechanical Engineers, 1 Birdcage Walk, London, SW1)

Structure of Tracks of Charged Particles in Condensed Media, Second L H Gray Memorial Conference, April 8–10, 1969, Trinity College, Cambridge (Professor J. W Boag, Second L H Gray Memorial Conference, Department of Physics, Institute of Cancer Research, Clifton Avenue, Belmont, Sutton, Surrey).

Structure, Solid Mechanics and Engineering Design in Civil Engineering Materials, April 21–25, 1969, University of Southampton (Secretariat, M Te'eni, Department of Civil Engineering, University of Southampton, Southampton)

NATO Advanced Summer Study Institute on Superconductivity, June 17–29, McGill University (P R Wallace, Institute of Theoretical Physics, McGill University, Montreal, Quebec, Canada)

Technological Forecasting, June 23–25, University of Strathclyde (Mr R V Arnfield, University of Strathclyde, Livingstone Tower, Richmond Street, Glasgow)

Precision Electromagnetic Measurements, June 25–28, Boulder Laboratories of the National Bureau of Standards (Donald D King, Aerospace Corporation, PO Box 95085, Los Angeles, California 90045)

Natural Rubber Conference, August 28–September 5, Kuala Lumpur (Natural Rubber Conference 1968, RRIM, PO Box 150, Kuala Lumpur, Malaysia)

Physical Aspects of Noise in Electronic Devices, September 11–13, University of Nottingham (The Meetings Officer, 47 Belgrave Square, London, SW1)

Theoretical Chemistry Summer School, September 16–28, Somerville College and Mathematical Institute, Oxford (Professor C A. Coulson, Mathematical Institute, 24–29 St Giles, Oxford)

Erratum In the communication "Effect on Brain Enzyme and Behaviour in the Rat of Visual Pattern Restriction in Early Life" by Devendra Singh *et al* (*Nature*, 216, 1337, 1967), Table 2 should read

Table 2

Rearing condition	ChE activity*	Anterior cortex	Posterior cortex	Total cortex
VP	Mean	55 00	55 80	53 09
	σ_M	7 90	4 55	4 45
RVP	Mean	38 67	27 33	33 00
	σ_M	5 11	6 06	4 02
Difference		16 33†	28 47‡	20 09‡

* All ChE values are in moles ACh × 10^{10} hydrolysed/min/mg of tissue
† Significant at 0 05 level
‡ Significant at 0 01 level

The ChE activity for restricted visual pattern group (RVP) and visual pattern group (VP)

Erratum In the communication "Sites of Inhibition of DNA Synthesis by Kethoxal *bis*(Thiosemicarbazone)" by Barbara A Booth *et al* (*Nature*, 217, 250, 1968), dCTP in the legend to Fig. 1 should represent deoxycytidine not deoxycytosine

Erratum In the communication "Sialotonin Vasopressor Substance in Cat Submaxillary Saliva" by C Moriwaki *et al* (*Nature*, 217, 270, 1968), the second line of the penultimate paragraph refers to indolealkylamines. these should be indoleamines

Erratum In the article "Radio Emitting Electrons in the Galaxy and the Solar Modulation of Cosmic Rays" by K C Anand *et al* (*Nature*, 217, 25, 1968), the scale of the legend to Fig 1 should be in BeV and not GeV as shown The abscissa of Fig 2 should be Frequency (MHz) (Anticentre), and the third sentence of the third paragraph on page 27 should read "It may also be pertinent to stress here that the fitting in the high frequency end of Fig. 2*A* depends primarily on the assumed magnetic field because in this frequency region $I_\nu \propto L < H_\perp >^{y}$, where $y > 1$"

Erratum In the communication "Ultraviolet Photolysis of Sodium Nitrate Solutions in the Laboratory and by Sunlight" by E G Gori *et al* (*Nature*, 217, 248, 1968), columns 2 and 3 of Table 2 should read

α'	β'
Mole l^{-1} cal $^{-1}$	Cal $^{-1}$
2 70 × 10^{-3}	6 27 × 10
4 10 × 10^{-3}	3 47 × 10

Corrigendum In the communication "Proposed Procedure for the Allocation of Trivial Names to the Gibberellins" by J MacMillan and N Takahashi (*Nature*, 217, 170, 1968) the structure of Canavalia-II was incorrectly drawn, the OH group should not have been present

Corrigendum *Textbook of Fluid Dynamics*, by Frank Chorlton, which was reviewed in *Nature* (217, 199; 1968), is available as a library edition in cloth boards for 70*s*, as well as the paperback version at 35*s*, which was reviewed

FORTHCOMING EVENTS

(*Meetings marked with an asterisk are open to the public*)

Monday, February 12

University of London (in the Botany Theatre, University College London, Gower Street, London, WC1), at 5 30 p m —Dr R J Benthem (Utrecht) "Conservation of Land Use Development I Reconstruction of Landscape" *

Institution of Mechanical Engineers, Manipulation and Mechanical Handling Group (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion Meeting on "Passenger Handling"

Tuesday, February 13

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, NW1), at 5 p m —Scientific Papers

Institution of Electrical Engineers, Control and Automation Division (joint meeting with the Automatic Control Group of the I Mech E, at Savoy Place, London, WC2), at 5 30 p m —Discussion meeting on "Control in Respiration" opened by Professor J M Nightingale

Royal Institution (at 21 Albemarle Street, London, W1), at 5 30 p m — Professor R J Harrison "Reproductive Patterns" (Lecture for Sixth Form Boys and Girls from Schools in London and the Home Counties To be repeated on February 14, 20 and 21)

University of London (at the Institute of Child Health, Guilford Street, London, WC1), at 5 30 p m —Dr D A J Tyrrell "The Possible Chemotherapy of Respiratory Virus Diseases" (Tenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)*

Institution of Electronic and Radio Engineers (at 8–9 Bedford Square, London, WC1), at 6 p m —Mr P Cooke "The M O S T Integrated Circuit"

Institution of Mechanical Engineers, Automobile Division (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Mr C G O'Neill "Mixture Conditioning for Reduced Exhaust Emission"

Institution of the Rubber Industry (at the Eccleston Hotel, Victoria, London, SW1), at 7 p m —Mr M Williams "Value Analyses—a Management Technique"

Wednesday, February 14

Royal Institution, History of Science Discussion Group (at 21 Albemarle Street, London, W1), at 1 p m —Professor James Greig "Engineering and Scientific Technique—The Contribution of John Hopkinson" *

Institute of Navigation (at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London, SW1), at 2 15 p m —Mr L R Colquhoun "The Operation of Hovercraft"

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street London, WC1), at 5 p m —Professor A P Dempster "A Generalization of Bayesian Inference"

Institute of Petroleum and the Institute of Fuel (at 61 New Cavendish Street, London, W1), at 5 30 p m —Mr W R Dorrensteijn, Mr H Verkoren and Mr G P Reman "Causes and Remedies of Combustion Noise in Refinery Plant"

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, WC2), at 5 30 p m —Mr F J M Laver "Stimulus or Constraint? The Interplay of Computer Design and Use"

University of London (at the Institute of Child Health, Guilford Street, London, WC1), at 5 30 p m —Professor B S Platt "Some Features of Protein-Calorie Deficiency in Man and Animals" *

University of London (in the Botany Theatre, University College London, Gower Street, London, WC1), at 5 30 p m —Dr R J Benthem (Utrecht) "Conservation of Land Use Development II Landscape Planning in New Areas" *

Royal Society of Arts (at John Adam Street, Adelphi, London, WC2), at 6 p m —Professor Harry Harris, FRS "Human Genetics and Biochemical Individuality" (Sir William Jackson Pope Memorial Lecture)

Society of Environmental Engineers (in the Mechanical Engineering Department, Imperial College, London, SW7), at 6 p m —Dr P Grootenhuis "The Use of Visco-Elastic Materials to Control Vibrations"

University of London (at the Institute of Archaeology, 31–34 Gordon Square, London, WC1), at 6 p m —Lt Comdr D W Waters, RN "Sources of Maritime Archaeology—History of Navigational Instruments" *

Society of Chemical Industry, Food Group—Food Engineering Panel (at 14 Belgrave Square, London, SW1), at 6 15 p m —Mr N G Ross "The Importance of Residence Time in Continuous Food Processing"

Institute of Information Scientists (at Knightway House, 20 Soho Square, London, W1), at 6 30 p m —Mr M Goldsmith "The Science of Science Foundation"

Pharmaceutical Society of Great Britain, and the British Society for the History of Pharmacy (at 17 Bloomsbury Square, London, WC1), at 6 30 p m —Mr F W Adams "The Pharmacy Act 1868"

Thursday, February 15

London Mathematical Society (at Burlington House, Piccadilly, London, W1)—Dr P Dembowski "Designs and Permutation Groups"

Institution of Electrical Engineers, Control and Automation Division (joint meeting with the Automatic Control Group of the I Mech E, and the Institute of Measurement and Control, at Savoy Place, London, WC2), at 2 30 p m —Colloquium on "Direct Digital Control of Systems and Processes"

Oil and Colour Chemists' Association, London Section (in the New Engineering Block, University College, Gower Street, London, WC1), at 2 30 p m —Paint and Printing Ink Conversazione Papers by Mr T R Bullett, Mr C C Mill, Mr C J H Monk, Dr Rohrer, and Dr Wagener

Society for Analytical Chemistry, Biological Methods Group, an Radiochemical Methods Group (at the Pharmaceutical Society, 17 Bloomsbury Square, London, WC1), at 2 30 p m —Meeting on "Radiochemical Methods Applied to Biological Investigations"

Royal Society (at 6 Carlton House Terrace, London, SW1), at 4 30 p m —Professor W S Fyfe "Experiment and the Crust of the Earth"

Institution of Mining and Metallurgy (at the Geological Society Burlington House, Piccadilly, London, W1), at 5 p m —Dr E Cohen, Dr J Mizrahi, Mr C H J Beaven and Mr N Fern "The Residence Time of Mineral Particles in Hydrocyclones", Dr J Mizrahi and Dr E Cohen "Studies of Some Factors Influencing the Action of Hydrocyclones", Mr M P Jones, Dr J Gavrilovic and Mr C H J Beaven "Colour Synthesis as an Aid to Electron-Probe X-ray Microanalysis"

Linnean Society of London (at Burlington House, Piccadilly, London, W1), at 5 p m —Dr G L C Bertram and Dr C K R Bertram "The Bionomics of Dugongs and Manatees", Professor A J E Cave "The Cetacean Reniculus"

Institute of Petroleum, Economics and Operations Group (at 61 New Cavendish Street, London, W1), at 5 30 p m —Mr G W Sears "Distribution Models"

Institution of Civil Engineers, Transportation Engineering Group (at Great George Street, Westminster, London, SW1), at 5 30 p m —Informal Discussion on "Transportation Systems in New Towns" introduced by Mr J M Stevens and Mr P B Green

Institution of Electrical Engineers, Power Division (at Savoy Place, London, WC2), at 5 30 p m —Discussion meeting on "Voltage Measurements of High Voltage Transmission" opened by Mr N Ashton

University of London (at the Institute of Child Health, Guilford Street, London, WC1), at 5 30 p m —Dr R J W Rees "Recent Advances in the Study of the Leprosy Bacillus" (Eleventh of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)*

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, SW1), at 6 p m —Mr J R Ryder and Dr A J Majumdar "Glass Fibre Reinforced Cement and Plaster"

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W1), at 7 30 p m —Dr J R Audy "Implications for Trematode Control of Inter-Specific Larval Antagonisms within the Snail Host", Dr C A Wright "Some Views of Biological Control of Trematode Diseases"

Thursday, February 15—Friday, February 16

Biochemical Society (at the Middlesex Hospital Medical School, Cleveland Street, London, W1)—479th Meeting Joint Colloquium with the Society for Endocrinology on "Characterization and Identification of Small Molecules of Biological Importance", and an ordinary meeting followed by a lecture on "New Methods for Finding Scientific Information"

Friday, February 16

British Computer Society (at the Connaught Rooms, Great Queen Street, London, WC2)—Symposium on "The Basis of Business Information"

Royal Institution, Photochemistry Discussion Group (at 21 Albemarle Street, London, W1), at 1 p m —Dr C M Trumbore "Excited States in Radiation and Photochemistry" *

Society of Chemical Industry, Oils and Fats Group (at 14 Belgrave Square, London, SW1), at 2 30 p m —Mr H B S Conacher "Rearrangement of Methyl Epoxyoleate and Related Epoxy Esters", Mr R W Williams "The Effect of Cholesterol on the Lecithin/Water System", Mr B K Bullimore "Evaluation of a Cheap NMR Apparatus for Oils and Fats Analysis", Mr D Illingworth "Zone Refining of Fatty Acids"

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, WC2), at 5 30 p m —Mr J K V Lee "A Position Fixing Aid to Marine Surveying"

Royal Institution (at 21 Albemarle Street, London, W1), at 9 p m — Dr Roger Bannister, CBE "Science and the Athlete"

Saturday, February 17

Inner London Education Authority (at the Horniman Museum, London Road, Forest Hill, London, SE23), at 3 30 p m —Mr Nicholas Guppy "Forest Indians of Southern Guiana—the Wai-Wais and Mawayans" *

Saturday, February 17—Monday, February 19

Field Studies Council (at the Orielton Field Centre, Pembroke)— Symposium on "The Biological Effects of Oil Pollution on Littoral Communities"

Monday, February 19—Wednesday, February 21

Materials Science Club (at the City University, St John Street London, EC1)—Informal Meeting on "Materials for Fuel Cells and High Energy Density Rechargeable Batteries"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Senior Demonstrator (with an honours degree in geology with particular interests in mineralogy, petrology or economic geology, and preferably experience in geochemistry or in X-ray techniques) in Geology at the University College of Townsville, University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (February 16)

Reader/Senior Lecturer (with substantial research experience in building acoustics and noise) in Building Science—The Staff Officer (606/6), The University of Aston in Birmingham, Gosta Green, Birmingham, 4 (February 17)

Assistant Lecturer in Organic Chemistry—The Registrar, University of Leicester, Leicester (February 24)

Agricultural Science Graduate (with an honours degree or equivalent) in the Soil Fertility/Chemistry Department—The Director, An Foras Taluntais (The Agricultural Institute), 33 Merrion Road, Dublin 4, Republic of Ireland, quoting Ref N3 (February 28)

Chair of Veterinary Pathology—The Secretary of the University Court, The University, Glasgow (February 29)

Chemist (with HNC, LRIC or BSc degree) to work on soil organic matter/trace elements, and a Chemist/Physicist (with HNC, LRIC or BSc degree) to study soil minerals by X-ray diffraction—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref 1052/105 (February 29)

Laboratory Steward (with HNC or higher qualification and considerable experience in a university laboratory)—The Secretary, Inorganic Chemistry Laboratory, University of Oxford, South Parks Road, Oxford (February 29)

Temporary Lecturer or Assistant Lecturer in the Department of Psychology to lecture on animal behaviour and the biological foundations of psychology—The Registrar, University Senate House, Bristol 2 (February 29)

Lecturer or Assistant Lecturer (preferably with postgraduate experience and interests in the field of metamorphic petrology) in Geology at Fourah Bay College, University of Sierra Leone—The Inter-University Council, 33 Bedford Square, London, WC1 (March 14)

Lecturer or Assistant Lecturer (with a degree in agriculture or tropical agriculture plus graduate experience in the tropics or sub-tropics, and preferably experience in the field of agricultural education) in Crop Production at the University of Botswana, Lesotho and Swaziland, for duties in Swaziland at the Agricultural College and University Centre—The Inter-University Council, 33 Bedford Place, London WC1 (March 20)

Chair of Physics at the Australian National University—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, April 8)

Assistant Professor (with experience in bacterial chemistry and/or metabolism) of Microbiology—Dr A J Rhodes, Head, Department of Microbiology, School of Hygiene, University of Toronto, Toronto 5, Ontario, Canada

Biochemist (preferably with experience with liver perfusion techniques and enzymes) to assist in research on bile pigment metabolism—Dr B H Billing, Medical Unit, Royal Free Hospital, Gray's Inn Road, London, WC1

Botanist/Plant Physiologist (with a good honours degree, sound experience in physiological and biochemical techniques and adequate research achievement) for studies on the biological changes accompanying maturation and senescence of fruits under selected storage regimes, with particular reference to the physiological disorders arising during long storage and to the application of the results of basic research—The Secretary, East Malling Research Station, Maidstone, Kent

Graduate Biochemist (preferably with research experience in separative biochemical methods) in the Department of Pharmacology to assist in a research programme on the metabolism of cerebral tissues—The Clerical Officer, Unit for Brain Metabolism, Department of Pharmacology, University Medical School, Teviot Place, Edinburgh, 8, Scotland

Research Assistant in the Department of Chemistry for research on proteins—The Administrator, Department of Chemistry, University College London, Gower Street, London, WC1

Research Assistants (qualified students wishing to work towards the MSc or PhD degrees) in Physiology—Dr D H Copp, Head, Department of Physiology, University of British Columbia, Vancouver, 8, B C, Canada

Research Technician/Junior Technician in the Pathology Department to work full-time on projects involving tissue culture, fluorescent microscopy, histology immunological techniques—The Secretary, Guy's Hospital Medical School, London Bridge, London, SE1

Senior Technical Assistant (with previous experience of work in chemical laboratories and ability to undertake responsibility for experimental investigations without detailed supervision) in the Chemistry Department of the Chester Beatty Research Institute Fulham Road, SW3—The Secretary, Institute of Cancer Research, Royal Cancer Hospital, 34 Sumner Place, London, SW7, quoting Ref 301/B/309

Technical Officer in Chemistry (with a university degree or equivalent) in the Metabolic Unit—The Secretary, Royal Postgraduate Medical School, Ducane Road, London, W12

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue

The direct postal price per subscription for one or two copies of NATURE each week is

***12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire		**£14 0 0** each
United States of America	(by air freight)	**$48** each
Canada	(by air freight)	**$52** each
Elsewhere overseas by surface mail		**£14 0 0** each

(Charge for delivery by air mail on application)
*Shorter periods *pro rata* (Minimum three months)

MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered

12 MONTHS (52 issues and 4 indexes)

Number of Copies	*G B & Eire*	*U S A.* (*by air freight*)	*Canada*	*Elsewhere (surface mail)*
	Each	*Each*	*Each*	*Each*
3–5	**£13 10 0**	**$46 50**	**$50 50**	**£13 10 0**
6–11	**£12 15 0**	**$44 50**	**$48 30**	**£12 15 0**
12 or more	**£12 0 0**	**$42 50**	**$46 00**	**£12 0 0**

Multiple subscriptions must run concurrently Every copy will be posted separately and for speed of delivery each subscription can be addressed to a different individual or department at the same address (ZIP essential for U S A)

Is Technology Here to Stay?

THE Ministry of Technology has enlivened and sometimes illumined the character of government in Britain for three years now, and after a shaky start it has won for itself a degree of permanence or at least the appearance of permanence. It is, for example, a long time since even the people in charge were not quite sure how to translate into administrative action the profound conviction of their government that the deficiencies of the British economy were largely attributable to defects in the structure of British industry. It is also a long time—or at least it seems like it—since there was a hankering after the belief that a handful of wise men around a committee table could solve problems which were beyond the wits of rapacious industrialists. Paradoxically, the succession of economic crises in the past three years has helped to give Mintech, as the Ministry of Technology likes to call itself, a better sense of proportion. After all, governments which are forced against their will and to their own surprise to devalue their currencies are not in the strongest position to offer unsolicited advice to industrial companies which, for all their faults, have at least managed to stay in business. Inevitably, and sensibly, the Ministry of Technology has become in the brief spell of its existence more like a midwife of change than an aspiring magician.

In the circumstances, however, it is not impertinent to ask precisely what the Ministry of Technology is for, and in looking for an answer it is probably more charitable to go by what the ministry does than by what it says. The trouble is that public statements on the subject are almost inevitably filled either with platitudes or even with fatuities. In a recent lecture at Imperial College, for example, the Minister of Technology, Mr Wedgwood Benn, cheerfully announced that "for the first time it is possible to compare projects across the whole field of engineering and to begin the difficult task of evolving criteria which allow intelligent choices to be made between alternative developments in different fields". Most people will agree that this is a sensible goal at which to aim, although some will raise the question of whether governments can allow themselves to be so involved in the process of planning industrial developments without at the same time finding themselves uncomfortably identified with the failures as well as the successes. The trouble is that it is also an ambitious goal, and there is at present no reason for believing that it is within the grasp of the Ministry of Technology or even the Government as a whole. In practice, indeed, the ministry's successes so far have not been steps towards this grand design but, rather, sensible and exceedingly empirical attempts to deal with industrial problems which have become so acute that they cry out for attention. It is easy to see how a sense of progress towards distant objectives helps to sustain the ministry's courage in adversity, but it is bound to be distracting for those outside.

This is a pity, for a good many of the things which the ministry has done are likely to be most valuable. There is, for example, a scheme to encourage the development of new kinds of machine tools by making it possible to spend public money on the first few production models. This will help to secure in Britain some of the benefits which are obtained in the United States (with less fuss) by the scale and the manner of spending on defence research. There is also a great deal of good sense in the ministry's plan to do something for the chemical engineering plant manufacturing industry, partly by advice, partly by research, development and consultancy at the ministry's research establishments and partly, no doubt, by an attempt to group some of the small companies in the industry into larger units. In time, no doubt, the ministry will be able to do valuable work in this field, not least of all because the men responsible for these developments are patient creatures and knowledgeable as well. In the same way, there now seems to be some evidence that the attempt to use the efforts of the 9,000 technically qualified people under the ministry's umbrella for industrial research and development is beginning to bring rewards (see page 607), although it would probably be foolish to imagine that what has worked with some success at Harwell can become a means of avoiding altogether the problem of how to deal with defence research establishments which, for one reason or another, have outgrown their original tasks. Whether the ministry's efforts to produce "a flourishing computer industry" will eventually be successful is another matter, although it is only proper to acknowledge that luck and IBM between them will probably have a greater influence on the outcome than anything the ministry can do. In these and many other ways, the ministry has functioned well when it has set out as a kind of industrial entrepreneur, willing to seize on whatever opportunities present themselves. It has also, however, won some more general victories. The ministry has, for example, provided a good deal of the drive behind the Industrial Reorganization Corporation, which has itself done much to set in train what amounts almost to an epidemic of mergers in British industry. The ministry has also been able to establish the principle that the Government's intervention in industry should ideally consist of encouragement for the successful enterprises, not support for the unsuccessful. In the long run, this inegalitarian doctrine should bring important benefits.

In other ways, however, the Ministry of Technology has been less successful. On many occasions, for example, it has spread itself too thinly. Sometimes plans which have been broached to the people most directly affected have then been put into cold storage for lack of people or money to follow them through. On other occasions the ministry has been downright inconsistent or ambiguous. What, for example, is its policy towards the research associations? What precisely does it mean by the European Technological Community? Then, with the most human frailty, it tends to grasp the thorny nettles last of all—there is, for example, little sign of movement on the reorganization of the nuclear power industry. Elsewhere the ministry's influence, no doubt unwittingly, has been mischievous. Its joyful espousal of the cause of tribology has been indecently innocent. By going out of its way to make technology respectable (which it is), the ministry has cast what it calls pure science in a villain's role and it will be a serious matter if that becomes a permanence.

At this stage nobody can know precisely what the future holds. The Ministry of Technology may have been able to prove the point that governments can usefully play a creative part in industry, but it does not follow that the patterns of administration now being created will last indefinitely. And in many ways, of course, success implies that the ministry will do itself out of a job. Now, for example that its efforts to weld the British companies in the British motor industry into a single unit have been successful, it is much easier for the ministry to wash its hands of the motor industry's anxieties. By the same test, if and when it rationalizes the computer industry, it will be able to retire gracefully to those sidelines as well. To say this, of course, does not mean that there will be nothing for the ministry to do, but rather that its industrial interests are bound to change frequently with the passing of time. In the circumstances, it is hard to see just what part the ministry's laboratories will play in the continuing future—is there really a need for them? But if it were not for the laboratories, what distinction would there be between the Ministry of Technology and several other agencies of government—the Board of Trade, the Ministry of Power and the Department of Economic Affairs, for example? In other words, although the Ministry of Technology has made a useful start, and although the foreseeable future is crammed with work, it will not be surprising if ten years from now the pattern of administration is radically different from what it is at present. And the test by which it will eventually be judged is whether, like the midwife it should aim to be, it will be prepared to retire gracefully once it has done its obvious job in some sector of British industry. The signs are not always encouraging.

Expensive Nuclear Power

The controversy over the way in which British nuclear power plants are built is not being allowed to die a quiet death. Mr Norman Atkinson, Labour Member of Parliament for Tottenham, has tabled a motion in the House of Commons urging the Government to implement the findings of the Select Committee on Science and Technology, of which he was a member. The committee, which produced its report in December 1967, said that nuclear power stations in Britain should be designed by one large group, taking in all the experience of the existing three consortia and of the Atomic Energy Authority. Mr Atkinson has since resigned from the committee, because, he says, he did not agree that an all party body was the right way for a Labour Government to determine its policy on nuclear power. Despite this, his motion that the recommendations of the select committee be now implemented has been tabled, and has the support of over one hundred Labour Members of Parliament.

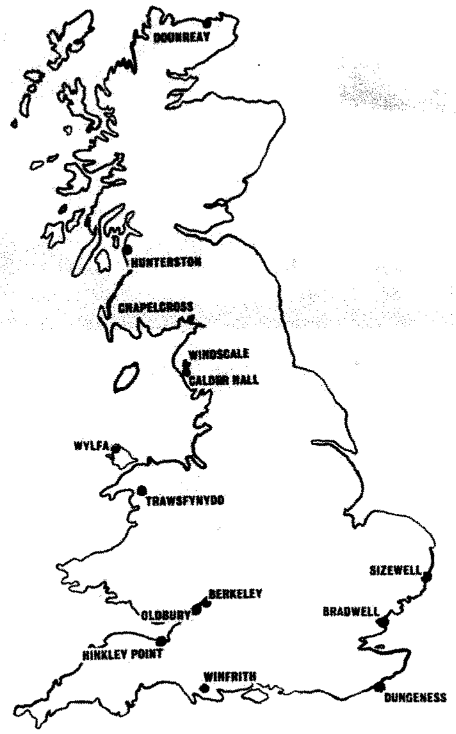
Mr Atkinson is convinced that the way in which the Central Electricity Generating Board has organized the building of power stations has cost Britain £40 million. This suspicion arose originally in the proceedings of the select committee, when it emerged that the CEGB had approved a change in the design of the channel diameter between Dungeness *B* and Hinkley Point *B*, the first two advanced gas cooled reactors to be built. It was claimed that, if this change had not been made, some £11–13 million could have been saved on Hinkley *B*. Both the CEGB and the Nuclear Power Group, makers of Hinkley *B*, indignantly dismiss the charge, and it is probably fair to say that other members of the select committee were doubtful about it too. Very little was made of it in the report. Mr Atkinson has now extended the same argument, claiming that, if all the first four AGRs had been identical, £40 million could have been saved on the capital cost of £320 million. "The CEGB commissioned virtual replicas, but did not get the economic saving of replication," Mr Atkinson says. The civil engineering work on all the power stations was also far too expensive—companies from the United States could have done it for half as much.

All this is likely to be taken as just another example of Mr Atkinson's enthusiastic approach to politics. There may well have been mistakes in the arrangements of the first few AGRs, but it is very unlikely that they will cost as much as Mr Atkinson claims. The difference between United States capital costs and British ones is at least as much a function of the design of the reactor system as it is of civil engineering inefficiency. But it is entirely sensible of Mr Atkinson to feel that it is about time the Government made up its mind about the future pattern of nuclear power in Britain. Until the select committee report was published, there was almost an excuse for inaction, but by now the Government can quite properly be accused of indecision. Mr Atkinson claims that the Government is under pressure from the consortia to retain the existing system—which is doubtless true—and that the CEGB also opposes the single design authority. Even if the Government were not on the point of announcing new nuclear power stations to provide power for aluminium smelters, there would still be no excuse for further delay.

Sites for Nuclear Power

The British Government clearly intends to build nuclear power stations much nearer to centres of population. In the House of Commons last week, Mr Richard Marsh, Minister of Power, said that some modification of the policy of building nuclear stations in remote places was now possible. The minister was acting on advice given him by the Nuclear Safety Advisory Committee, which had said that the principal safeguard to public health came from the high standards of design, construction and operation of nuclear stations. For gas cooled reactors built in pre-stressed concrete vessels, it was clear that it was safe to build them much nearer to cities than had been customary. Mr Marsh said that this meant any area with a population density sufficiently light to evacuate the people within a range of 1·5 to 2 miles in the unlikely event of an accident. He agreed that this included the areas around Hartlepools and Heysham, both possible sites for nuclear stations.

The decision raises some interesting issues. Although most people agree that a relaxation of the restrictions is timely, particularly in Britain where isolated sites are hard to find, the decision of the committee refers only to British gas cooled reactors. What would happen if the generating boards decided to build a water reactor in the United States style (as they have sometimes threatened to do) is not made clear. A direct comparison of the safety of the two reactor types has not been made—so far both have a completely clean record, although it has been suggested that gas cooled reactors are inherently safer. The decision also clears the way for the generating boards to replace some of their older coal fired stations with nuclear stations, making better use of sites nearer to towns. As the map shows, all British nuclear stations so far built are in fairly remote areas, which has tended to increase the costs of building and of transmitting the power to the point of use.



In other parts of the world which lack the sophisticated grid system in operation in Britain, the advantages of building near towns may be even greater. This, it is hoped, may help the export of British power stations, perhaps to Germany. As Mr Eric Lubbock mentioned in the short debate in the Commons, a power station is to be built near Ludwigshafen in West Germany; Mr Marsh pointed out that another is to be built within 20 miles of Hamburg. The fact that Britain is now willing to build as near as this to towns will lend some weight to the tenders made by British consortia. In the United States, Consolidated Edison did once propose to build a station in New York, but were dissuaded by the Atomic Energy Commission. Despite this, the same tendency for generating stations to get ever nearer to towns has been observed in the United States. One of the problems which dictates a cautious advance, however, is the way in which the size of nuclear stations has increased. In this sense, Mr Marsh is disingenuous to claim that Britain has 132 nuclear years of experience. Until Dungeness *B* starts operating, Britain has no actual experience of a commercial advanced gas cooled reactor. The experience is on the less sophisticated—and generally smaller—magnox reactors.

Kidney Transplants

THE ethical problems of transplanting organs are to be discussed at a conference announced on February 14 by Mr Kenneth Robinson, Minister of Health. The conference will be chaired by Sir Hector MacLennon, President of the Royal Society of Medicine, and will include lawyers, leading churchmen and laymen as well as doctors. Although the conference will be private, there seems some chance at least of a joint communiqué being issued after it is over. The ministry has emphasized that the purpose of the conference is to discuss the problems that have arisen in the provision of kidneys for transplant operations in Britain, and not to embark on lengthy discussions of the more controversial subject of heart transplants. So far, because there have been no heart transplant operations in Britain, the discussion of the subject has been less acrimonious than elsewhere, but there have already been signs of sharp disagreement. The minister will be hoping to steer the discussion away from such potentially dangerous topics.

Kidney transplantation is a much less heated subject; almost everybody agrees that in principle it is a very good thing. But technical difficulties over the provision of kidneys from donors have at times made the surgeon's task harder than it might have been. Some surgeons feel that the law should be amended so that kidneys could be taken from fatally injured people without consent from relatives. The difficulty here is that the kidney must be removed from the patient very soon after death if it is to be of any use to the patient.

Guidance for Universities

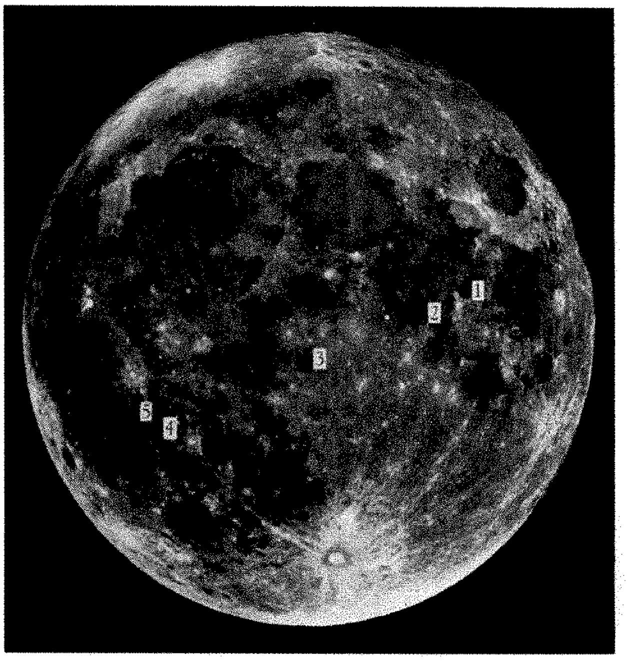
BRITISH universities have now been provided with some cautious guidance on the degree to which lecture rooms and laboratories are being used. This information is the first product of the work of the sub-committee under Mr C. F. Carter, Vice-Chancellor of the University of Lancaster, which has been brooding on the utilization of university facilities for the best part of a year. The report now being sent to universities is based on a survey in sixteen institutions which has been carried out by Mr K. S. Davies, the research officer attached to the project by the vice-chancellors' committee. At this stage it is clear that everybody is anxious not to let the universities feel that they are being coerced into a uniform pattern of teaching, and the report is offered as a means of providing "universities with a means of comparing their use of capacity with others". It remains to be seen whether the project will have more to say, in the years ahead, about the ways in which universities should manage their affairs, but the report says that the next step is to estimate what savings and qualitative improvements would be possible "if optimal patterns of use are adopted". Eventually, the argument runs, the universities would then be more able to formulate accurate plans for capital expenditure. The report also looks forward to a kind of advisory service equipped to keep a continuously watchful eye on university practices and able to offer advice about the ways in which universities might get better value for money.

Mr Davies explained, earlier this week, that there is not yet a tangible plan for setting up a continuing organization to superintend the ways in which universities make use of their facilities. The progress report which has now been issued says very little about British university practice in present circumstances, but there is a brief statement that, in the universities already surveyed, the "occupancy factor" of teaching rooms works out at 75 per cent, which is "no mean performance" compared with the average occupancy of 30 hours a week out of 45 in the universities of Washington and California. This brief statement is, of course, quite unconvincing without supporting evidence and has on this account provoked some sarcasm in the daily newspapers. Mr. Davies explained during the week that more detailed information had been circulated to the committee of vice-chancellors, though it is not yet clear whether this is already being used for purposes of comparison by British universities. He emphasized that his enquiries were only at a preliminary stage and explained that in any case the details of his work would not be understandable "to people outside the universities".

Landing Sites on the Moon

The National Aeronautics and Space Administration (NASA) has completed its selection of landing sites on the Moon for the Apollo astronauts. Five areas, each three by five miles in size, have been chosen by the Apollo Site Selection Board, it was announced last week. Site selection has been achieved through the photographic survey carried out by the Lunar Orbiter series of spacecraft reinforced by the spot checks of the Surveyor landers. At the beginning of the survey programme thirty tentative sites ranged along the Moon's earthward face were under consideration. The observations of the survey spacecraft reduced these to eight "possibles". From these, the board has selected the five target sites and the Apollo men will leave for their mission not knowing which of three they will use.

All five sites lie within a quite narrow band along the lunar equator—within 45° east and west of the visible Moon's centre and 5° of the equator, the so-called Apollo Zone of Interest, where optimum conditions for communications and surveillance from Earth of the astronauts' progress exist. Two are in the Sea of Tranquillity, one in the Central Bay, and two in the Ocean of Storms (Mare Tranquillitatis, Sinus Medii, Oceanus Procellarum). Apart from this, each site has had to satisfy seven other criteria necessary for the safety of astronauts. These are relative freedom from craters and boulders; a smooth approach path without large hills, cliffs or deep craters likely to cause inaccurate altitude signals on the landing radar; a slope of less than 2° over the landing site and approach path; central grouping enabling the least expenditure of propellant by the lunar module; optimum visibility for the approaching astronauts in guiding their craft down which requires that the Sun angle should lie between 7° and 20° and come from behind the craft at landing. This last criterion gives a 1-day launch window each month. The intervals between the sites have had to correspond with the time needed to re-cycle the Apollo/Saturn V if there is a check during initial countdown; and, finally, site location must be within reach of the Apollo "mothership" on a free-return trajectory, that is, where the spacecraft can coast round the Moon and return to Earth without employing propulsion. Altogether this will make a 3-day period each month available for launching the first Apollo flight.



The five sites chosen for the Apollo landing are in the Mare Tranquillitatis (1) and (2), the Sinus Medii (3), and the Oceanus Procellarum (4) and (5).

Contraception in France

General de Gaulle's dream of a French population of one hundred million by the end of the century is not likely to be greatly thwarted by a new French law on contraception, passed on December 19, 1967. Although this law, the Neuwirth law, may well serve to make contraception more respectable, it is in many ways unsatisfactory and has been widely criticized.

The history of events leading up to the formulation of the law reflects the absurdity of the situation. After the First World War, possibly because many Frenchmen had been killed, a notorious law was passed which made contraception illegal. Since then the only method of contraception to which the authorities have turned a blind eye has been the condom, which has come to be regarded as a prophylactic against venereal disease rather than as a contraceptive.

Various forms of oral contraceptives have been available in France for several years because of their initial therapeutic role, but not everyone can afford them.

The family planning association called the *Mouvement Français pour le Planning Familial* (MFPF) has, however, been operating "underground" and has until recently got around the law by running the organization on the lines of a club with paying members. The organization now has a membership of 100,000 and has more than three hundred centres.

According to the new law, decisions about the manufacture and importation of contraceptives will be subject to a ruling by the public authority, and the sale of contraceptive products will be subject to an authorization of the Minister of Social Affairs. The sale of such articles will be confined to chemists' shops, while those oral contraceptives placed on the so-called "special list" will only be sold under prescription; and the doctors concerned will be required to consider the patients' medical history. Minors up to 18 years old under parental control requiring contraceptives, and similar young people up to 21 years old requiring oral contraceptives on the special list, will have to have a prescription as well as the written consent of a parent or legal guardian.

Under the new law, family planning associations will not be allowed to supply contraceptives as they have done in the past. Another blow to such organizations is that all "antinatalist propaganda" will be forbidden, which means that people seeking advice from an association will have no means of finding it, either from advertisements, or, presumably, from telephone directories. The government intends to back up the law with fines and imprisonment for offenders.

Because the Social Security will not have to reimburse the costs of progesterones, as it does the cost of other medicines, some doctors contend that it is the poor who will suffer most. There is also a feeling that the law places too much responsibility on the doctors, allowing them to interpret it according to their moral and religious principles. Others feel that it is intolerable that patients should be so closely controlled in so personal a matter. One objector on medical grounds, Professor Jacques Huguier, has suggested that, if the law is not repealed before it comes into action on March 1, wholesale resignation of the medical profession might be called for. An extremist's view, perhaps, but it is evidence of the kind of opposition the law is meeting.

More European Physics

The plan for forming a European Physical Society has been modified somewhat in the light of the discussions of the steering committee which met on January 30 at the Battelle Institute in Geneva. For one thing, it has been decided to postpone the large conference which had first been hoped to inaugurate the society at Florence in September this year. This event will not now take place until 1969. Instead there will be an inaugural ceremony in Geneva in September this year. At the same time it appears that serious discussions have been opened with a number of countries from Eastern Europe—Yugoslavia, Czechoslovakia, Hungary and Rumania. Although the representatives of the physical societies in these countries have been given clearly to understand that the formation of a European Physical Society will not be obliged to allow them to determine their own relationship to it, there does now seem hope that they will eventually be associated with the work at some stage. In the meantime, it appears that there have emerged a number of difficulties about the financial provisions in the constitution although these will most probably be resolved at the next meeting of the steering committee due to be held in the spring this year. With luck this will be held in Prague, but otherwise in Vienna.

It has been agreed that the headquarters of the society will be in Geneva at the physics department of the university, 32 Boulevard d'Yvoy, 1211 Geneva 4. It has also been agreed that the working language of the society will be English. At the meeting on January 30 it was agreed that the European Chemical Society should publish a bulletin, principally to keep European physicists informed about the discussions now going on, but there seems some confusion about the way in which this will be accomplished. In the circumstances, it is not surprising that the steering committee has not yet had a chance to take up the more complicated question of how to organize the learned journals in physics which cater for European scientists. The first inclination seems to be to divide physics as a whole into fields which could be parcelled out to the journals which already publish original articles in physics, and in this spirit existing publishers are likely to be approached in the next two weeks. It would not, however, be surprising if in the end the European Physical Society decided to follow a more informal and more empirical course, if only for the sake of the flexibility it would thereby gain.

New Hope for Planning

The first rumblings of a new assault on national planning were heard last week when Mr Peter Shore, Secretary of State for Economic Affairs, presented a Government paper to a meeting of the National Economic Development Council. It appears that few details were given at the meeting, but it was stated that another paper would be presented after the budget on March 17, with broad outlines of the way the economy should develop. The economic development councils for the different sectors of industry will then be able to discuss the projections and work out what the effects will be on their own sections of industry. There are twenty-one councils, known affec-

Mr Peter Shore.

tionately and sometimes derisively as little Neddies, covering about two-thirds of private industry, with representatives from management and unions. When the results of their deliberations are known the Government will add them to results from its own studies and produce a more detailed planning document in the autumn. It is acknowledged that prices and incomes will be important considerations in any plan of this kind. The whole subject of national planning has been regarded rather sceptically since the National Plan was abandoned in July 1966, but it is thought that the present state of the economy calls for another attempt, provided that it is more flexible than the last.

New Look for Heathrow

The British Airports Authority, which runs commercial airfields in Britain, last week unveiled plans for the development of Heathrow, London's major airport. With the advent of the Boeing 747, which will be arriving on commercial flights to London by the summer of 1970, development of Heathrow to handle the increase in passengers has become urgent. Although the new plan is to cost £10 million, it represents a face-lift for only a small part of the airport.

The new section of the airport will be a T-shaped pier, with an upright 900 ft. long and a crosspiece 1,000 ft. long. The aircraft stands will be positioned along the crosspiece, seven each side, and passengers will be carried along the upright section on a travelling pavement. For those who prefer to make the journey on foot, ample space will be provided on either side of the conveyor. Telescopic air jetties will link the aircraft with waiting rooms. There will also be changes in the terminal buildings; a new passenger terminal building, prosaically called Terminal 1, will be built, and the existing Europa and Britannic buildings will be merged and called Terminal 2. The Oceanic building will be renamed Terminal 3, and a new arrivals terminal will also be built. By the time the 747 service across the Atlantic is in full swing, it will be necessary to separate arriving and departing passengers into two separate terminals. Thus by 1970, Terminal 3 (the Oceanic building to today's travellers) will be devoted to departing passengers, while the new arrival terminal looks after those coming into Britain. By this time, the authority says, the number of departing and arriving passengers on long haul services is likely to reach 2,700 an hour in each direction.

The main difficulty will arise when several 747s arrive at once, or within a few minutes of each other. Each will be carrying up to 490 passengers. Unless the capacity of the airport bus services is to be severely overstretched, a rail link between central London and the airport must be built.

Marine Science on Record

The first comprehensive directory of marine science in the United Kingdom has just been published (The Royal Society, £2). It has been prepared on behalf of the Royal Society's British National Committee for Oceanographic Research with the co-operation of the Natural Environment Research Council, and it should prove to be of great help to everyone working in this rapidly growing subject.

For the most part, the book consists of the names of scientists listed by establishment and arranged in four sections. Sections 1 and 2 include the marine science laboratories, both government and university, with details of the scientists employed in them and of the laboratories themselves. Information given under each institution includes facilities for visiting research workers, training courses, and a selected bibliography of research done there. There are as many as 57 university departments in the United Kingdom which have continuing interests in marine science.

Sections 3 and 4 cover university departments and government-supported laboratories in which marine science has only a minor role—but where there are staff working on some aspect of the subject. A further 42 academic and 13 government-supported departments are listed in these sections.

There is often confusion over the organization of research in interdisciplinary fields such as oceanography. It is helpful, therefore, that the directory includes a summary of the overall organization of oceanographic and fisheries research in the United Kingdom and the part played by the national programme in international activities.

The research ships available to British scientists and the libraries offering facilities to them are listed in two appendices.

Scientist on the Move

Mr B. T. Price, at present director of the Defence Operational Analysis Establishment of the Ministry of Defence at Byfleet in Surrey, is to become Chief Scientific Adviser at the Ministry of Transport on April 1. Mr Price has worked in turn for the Atomic Energy Authority and for the scientific group at the headquarters of the Ministry of Defence. He has been largely responsible for setting up the Byfleet establishment in the past few years. He is a physicist by trade.

Mr B. T. Price.

This new appointment comes at a time when it seems that the Ministry of Transport would like to see more of what the British Government spends on research and development devoted to the art of moving about.

Make or Break

During the past year or so, the Electrical Research Association has done its share of breast-beating in public. The decision by the Central Electricity Generating Board to withdraw its habitually automatic support was a shock from which ERA has taken some time to recover. Now, although workers at ERA are hoping the worst is over, there is still a certain amount of belt tightening to be done.

Under a scheme to be introduced next year, each item of research carried out at ERA will have to be individually sponsored. This is a system which will doubtless help to raise sums of money for jobs for individual companies, but is unlikely immediately to help ERA to continue work which is of general interest to the entire industry. The more general a problem, the less likely a company is to feel responsible for it. This difficulty is going to hit hardest at the work which is of greatest public concern—the safety of electrical devices, as ensured by the correct design of fuses. ERA performs a continuing service for fuse manufacturers, not least by ensuring that British companies keep up with changes in international standards, now recognized as a major barrier to successful exporting. The same section at ERA which is responsible for fuses also works on contractors, and has recently been able to show that British manufacturers were producing a product which was uneconomic because the standards were too stringent.

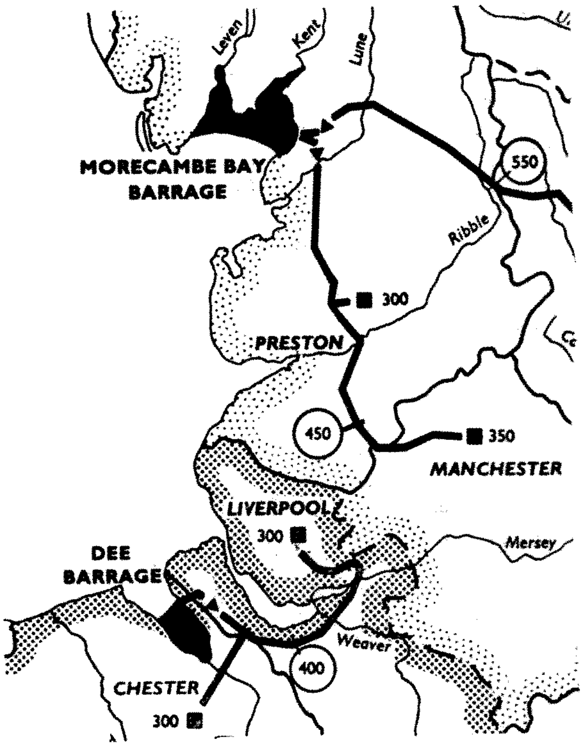
ERA has now published a summary of the literature in fuses between 1950 and 1965 (*Advances in Electrical Fuses*, by H. W. and C. Turner, ERA, 54*s*.). This, it is hoped, will stimulate British manufacturers to increase support for this important part of ERA's activities.

Biology of Barrages

Work is now in progress on the biological effects of the proposed barrage across Morecambe Bay. The full feasibility study announced early last year by the Water Resources Board is to cost about £500,000 and is expected to last another 2 to 3 years. By then the board, with reports in hand representing all sides of the project, should be able to advise the government whether the barrage is a workable proposition.

An important aspect of any barrage scheme is the effect the works will have on the ecology and fisheries of the area. The biologists must try to predict what will happen to the different animals and plants, bearing in mind the usefulness of the impounded water, the amenities of the area, the fisheries, and so on. One of the biological techniques used for a study of this kind is to find the nearest parallel project. Unfortunately, there are few examples of similar estuarine barrages to which the biologists can turn. The conversion of the Zuider Zee into the Ijsselmeer in Holland, however, may have some relevance, and Loch Neagh in Northern Ireland shows some similarities although it is an inland lake. Two biologists who are to work on the Morecambe Bay barrage have now been appointed by the Natural Environment Research Council. The co-ordinator of the ecological work is Mr John Corlett, who has been seconded to the Windermere Laboratory of the Freshwater Biological Association from the Fisheries Laboratory, Lowestoft. His assistant is based at the University of Lancaster.

The Nature Conservancy is also assisting in the study in several ways. A small department to study the overall conservation of large scale proposals has been recently established at the Nature Conservancy station at Shrewsbury under the direction of Dr R. J. Elliott. The proposed barrage is one of the projects with which it will be concerned, and it will keep in touch with the regional conservation staff and other interested parties. Meanwhile, a small ornithological project on waders is in operation in co-operation with the Royal Society for the Protection of Birds and the Ministry of Agriculture. It is necessary to know how many of these birds there are in the estuary and what they feed on. The Nature Conservancy has therefore issued a licence for a few waders to be shot so that their stomach contents can be analysed. Work on the coastal ecology of the estuary will be done from the Nature Conservancy's station at Merlewood, Grange-over-Sands.



The Morecambe Bay and Dee Barrages, with a suggested distribution system.

It will be some time before all the data collected can be assembled into a meaningful whole, but there is no doubt that there will be some important biological factors for the engineers to bear in mind when or if they come to actually designing the barrage.

Astronomers at Brighton

For the first time since 1925, the General Assembly of the International Astronomical Union is to be held in Britain. The next Assembly—the fourteenth—will meet in 1970 at the University of Sussex, near Brighton, from August 18 to 27. Judging by the numbers at previous Assemblies—the thirteenth was held in Prague last year—about 2,000 astronomers are expected to attend.

The chairman of the Preparatory Organizing Committee, Dr D. H. Sadler of the Royal Greenwich Observatory, is hoping that observatories and astronomy institutes in Britain will arrange visits for the astronomers during the Assembly. Many institutes in the United Kingdom may also wish to take advantage of the presence of visiting astronomers to organize meetings before or after the assembly. Dr Sadler, like conference organizers the world over, is hoping that his plans will not be marred by duplication.

Better Machines

The Ministry of Technology has devised a way of supporting the development of numerically controlled machine tools. It involves collaboration between a government establishment (RAE, Farnborough), a research association (the Production Engineering Research Association) and industry (Airmech AEI). These three are establishing a numerical control advisory and demonstration service, which will set out to tell industry what is possible and how it can be done.

Some industries in Britain are already aware of the importance of numerical control. Having a machine tool controlled by tape not only releases a man for other activities, but also improves precision and makes much better use of machines. A machine controlled by tape can be used for 60 per cent of the time, against 20 per cent for one controlled by hand. Numerically controlled machines need fewer jigs, and may also reduce lead times—the gap between design and production. Most of Britain's 1,400 numerically controlled machines are in the aviation industry, and other industries have tended to fight shy. The production engineers estimate that eventually 10 per cent of the machine tools in Britain will have to be controlled in this way, a total of perhaps 125,000 machines, so there is plenty of room for expansion.

One of the difficulties has been to get an unbiased assessment of just how valuable numerical control is. The new service should be able to provide this, although by identifying itself with the scheme, PERA may have sacrificed its objectivity as far as industrialists are concerned. PERA says that it has been able to show a 20–25 per cent return on the investment for most companies contemplating the investment, and that each survey costs in the region of £1,200. The new service provides for the ministry to pay between 50 and 90 per cent of the cost of such surveys, as well as paying for the training courses. At the same time, the ministry is supporting the establishment of a numerical control centre at High Wycombe by Airmech AEI Ltd. This will contain a workshop with a range of machine tools equipped with Airmech AEI control systems, and will undertake contract work for industry on a commercial basis, in order to prove how cheap and effective numerical control is. The total cost of the scheme will be £685,000, spread over three years, half of which will cover the cost of buying numerically controlled machine tools.

Infrared Geology

Fig. 1 shows an example of the infrared images (taken in the 8 to 13 micron band) which are providing information on the San Andreas fault system in the Carrizo Plain area of California. An aerial photograph is shown for comparison (Fig. 2). R. E. Wallace and R. M. Moxham have been taking pictures of 200 miles of the fault system as part of a joint project of the US Geological Survey and the National Aeronautics and Space Administration. The infrared image was taken before dawn, when the properties of the rocks and soil are best indicated. The strong white line on the left is a hard packed road. It is thought that the particularly dark patches in the fault line itself are due to accumulations of tumbleweed which have exceptionally low thermal inertia and thus produce relatively low radiation temperatures before dawn.

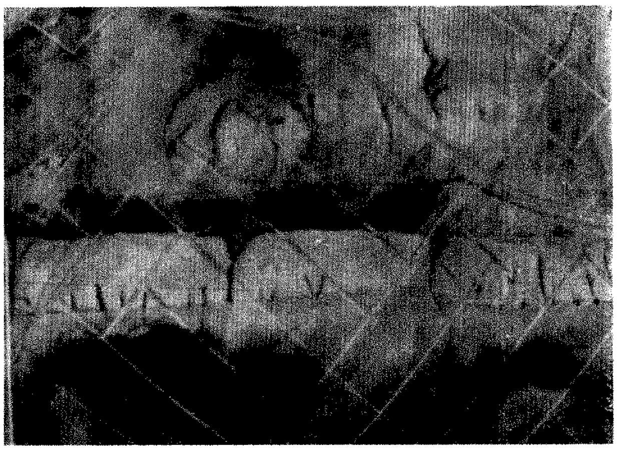


Fig. 1. Infrared image of part of San Andreas fault.

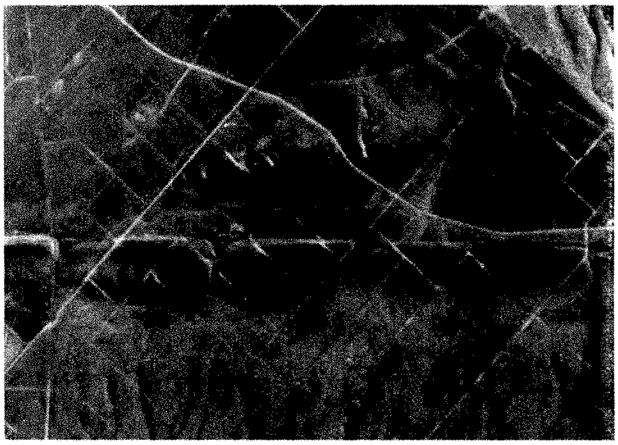

Fig. 2. Aerial photograph of the same area.

Building High

Much modern building, particularly of high rise blocks, would be impossible without the detailed knowledge of soil technology which has been developed, principally in this century. Buildings, of course, have always depended on the security of their foundations, but until comparatively recently empiricism ruled supreme. Mr R. Glossop, giving the eighth Rankine lecture to the Institution of Civil Engineers on February 14, gave some intriguing examples of this approach. When Tower Bridge was built over the Thames in the late nineteenth century, there seems to have been no serious examination of the geological conditions below the foundations of the bridge. There was little excuse for this, as the techniques were known—for Saltash Bridge, I. K. Brunel sank 175 boreholes for the central pier alone. For Tower Bridge it was decided, evidently on scanty scientific evidence, that the clay would bear a load of 4 tons/sq. ft; but contemporary engineers, who criticized the design, said that higher loadings would have been perfectly acceptable, and would have reduced the obstruction to the waterway. The consulting engineer, Mr John Wolfe Barry, fortunately stuck to his guns; Mr Glossop said that recent boreholes near the bridge had shown that greater pressures would have been unwise. Indeed, the whole design of Tower Bridge seems to have been blessed with good fortune; the depth of the clay is only some 10 feet and, had this been penetrated, there might have been serious difficulties.

This approach is happily now of historical interest only. Settlement is frequently a source of damage to old buildings, and Mr Glossop quoted the example of Westminster Cathedral, where the massive tower on the north face of the cathedral has settled more than the rest of the building. Much of the progress in soil technology is due to the classical work of Terzaghi, which has been developed since 1925 into a most important branch of engineering science. The turning point, at least as far as the loading capacity of soils is concerned, seems to have come in 1942, when the foundations of a single storey building in the Firth of Forth collapsed. The design failed because it had not taken into account all the geological factors; but it provided such a mass of data for the Building Research Station to analyse that it might have been designed as a laboratory experiment. The agreement between theory and experience was so good, Mr Glossop said, that it finally brought conviction to many unbelievers.

The most marked effect of the development of soil mechanics had come in the design and construction of earth dams. In 1866, Mr Glossop said, Jacob had confidently stated that it was "idle to pursue the investigation (of earth dams) by a mathematical mode of reasoning". He suggested a three to one slope on the upstream side, and a two to one slope on the downstream side, recommendations which were accepted without question until about 1940. In 1898, two engineers attempted to justify dams on which the slope flattened progressively from top to bottom on the grounds that Mount Fujiyama was that shape. Since then, Mr Glossop hastened to point out, the construction of earth dams had become a much more scientific activity, a claim which he proved by reference to the Derwent Dam, built on the borders of Northumberland and County Durham, and completed in 1967.

All Change at the Museums

SIR TERENCE MORRISON-SCOTT, Director of the British Museum (Natural History) since 1960, is to retire at the end of the year. The most important event in Sir Terence's term of office must have been the severing of the Natural History Museum from the British Museum on the passing of the British Museum Act, 1963. This meant that the Natural History Museum for the first time in its life was able to establish its own governing body of twelve trustees.

At the latest meeting of the trustees, two new appointments were also confirmed. Dr J. G. Sheals, Head of the Arachnida and Myriapoda section, is to be a deputy keeper in the Department of Zoology. Dr Sheals is particularly interested in the application of data processing equipment to the taxonomic catalogues in the museum. Another new deputy keeper—this time in the Department of Palaeontology—is to be Dr C. G. Adams, who works on the larger species of Tertiary Foraminifera. Dr Adams will transfer from the Zoology Department to the Palaeontology Department on taking up his appointment. Both appointments are effective from April 1.

A further announcement is that Lord Radcliffe has resigned as chairman of the Board of Trustees of the British Museum because of ill-health. His place has been taken over by Lord Eccles, who will now lead in the British Museum's efforts to persuade the Government to agree to the building of the new national library next door to the present museum. Lord Eccles appears to be as vehement as Lord Radcliffe in his condemnation of the Government's action over the museum. It is understood that Lord Radcliffe will remain a trustee, at least for the time being.

Science of Science

THE Science of Science Foundation is now in the fourth year of its existence. To mark the occasion, Dr O. M. Solandt, President of the Science Council of Canada, is to give the foundation's fourth annual lecture. The foundation has continued to mount a wide ranging programme of lectures and seminars, and is now publishing a bimonthly newsletter. It has also opened a library at the University of Sussex. These developments apart, there is as yet little sign of the activities proposed in March last year when the foundation launched an appeal for £282,000 (*Nature*, **214**, 1 and 3). It must be assumed that the appeal has not so far met with conspicuous success.

The foundation's newsletter (obtainable at the Ciba Foundation, 41 Portland Place, London, W1; annual subscription 2 guineas ($6)) is concerned with "topics of interest in the field of the science of science". With twelve pages an issue, the newsletter contains reports of the foundation's activities and other meetings, and reviews of relevant books and pamphlets. Science policy and other news from Europe, the USA and USSR are also covered. The newsletter began as a document for internal information, but outside demand for its services has already created a small but rising circulation.

Research on a Shoestring

THE Medical Research Council of Ireland has just published its annual report for 1966 (5*s*.). The impoverishment of medical research in Ireland is made blatantly obvious—the council, for example, has to do without a research director or a central research institute. The reason for this appears to be to ensure that as much of the council's grant as possible goes directly to the support of research. Most of the money is used to encourage research in medical school departments, but there is also one special university unit, the Unit for Cell Metabolism in the Department of Biochemistry, University College, Dublin, and one independent unit for studying chemotherapy specially set up by the council in Trinity College. Summaries of the research carried out by these units and research in other departments supported by the council are given in the report. This research is co-ordinated by the special committees set up recently by the council to advise it on the development of particular research fields. There are five committees in all, covering cancer, cardiovascular diseases, gastroenterology and haematology, metabolism and endocrinology, and pregnancy and congenital deformities.

In November 1965, the government increased the council's grant for general research by £10,000 a year, bringing it to £72,000 a year. The increase was, however, more than absorbed by salary increases, so that the council reports that the range of its activities is more or less at a standstill. Other grants from unspecified sources and a grant from the government for specific projects brought the total amount of money administered by the council in 1966 to £106,650.

Parliament in Britain

Foot and Mouth

LORD BESWICK said that the setting up of a committee of inquiry into control policy for foot and mouth disease was being considered as a matter of urgency. The appointment of the chairman might be announced in the fairly near future. Although the precise terms of reference had not yet been decided, they were likely to be similar to those given to the Gowers Committee: "To review the policy arrangements for dealing with foot and mouth in Great Britain and to advise whether any changes should be made in the light of present scientific knowledge and the technical and administrative experience gained in recent years in this and other countries". The experience of those employed in the present outbreak would best be made available as witnesses rather than as members of the committee. (Debate, House of Lords, February 5.)

Dungeness B

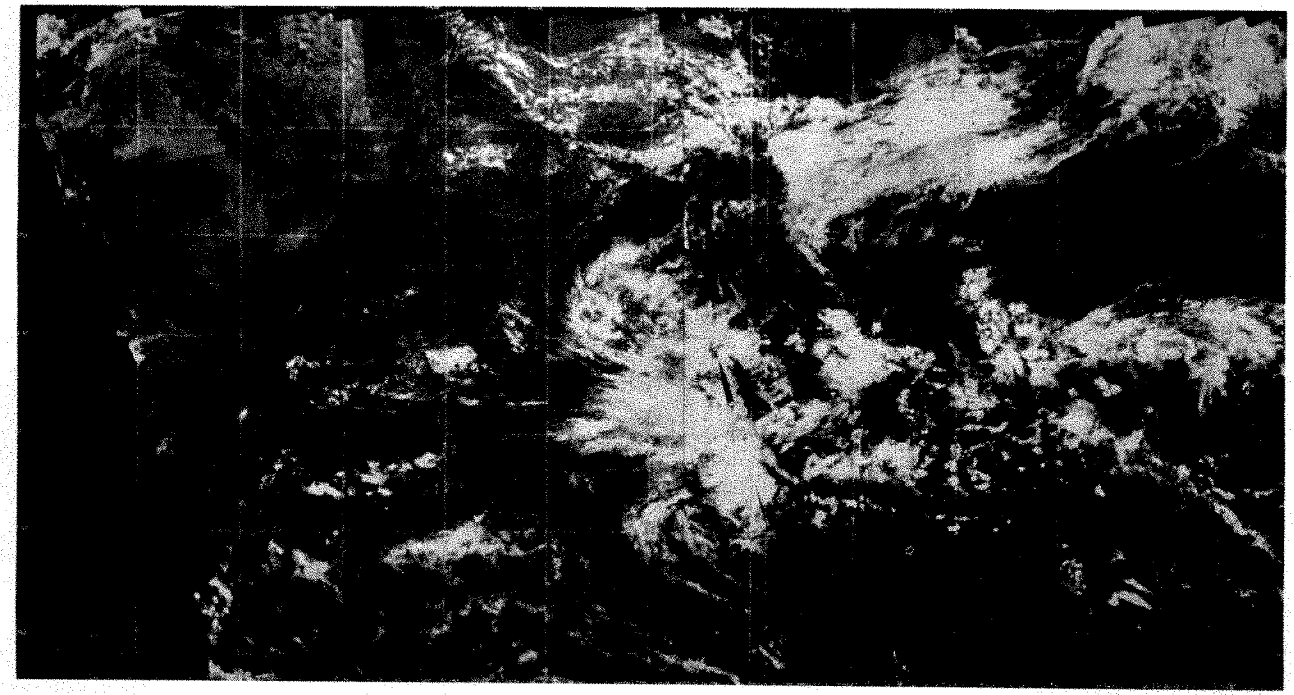
THE parliamentary secretary to the Ministry of Power, Mr R. Freeson, stated that the estimated base-load generating cost (including capital charges and operating costs) of the Dungeness B nuclear power station had increased by about 25 per cent since July 1965. The Central Electricity Generating Board advised that 8 per cent of this was due to increase in price levels, including the effects of devaluation, changes in ground rules and use of the same rate for interest during construction, 3 per cent to the inclusion of royalty payable to the Atomic Energy Authority, and 7 per cent to other causes. The station was expected to begin operating in 1970. (Written answer, February 6.)

Satellite Motors

IN answers in the House of Commons on February 5, the Minister of State, Ministry of Technology, Mr J. Stonehouse, stated that the first experimental model of an electrical thruster had been made at the Royal Aircraft Establishment and preliminary testing would start shortly. Initial research was being carried out on very low thrust electrical units suitable for maintaining the orientation of a satellite in orbit. A development programme on this initial research work came within a wider programme costing £3 million a year. (Written answer, February 5.)

Insects

A LIST of current research projects into the biological control of insect pests to which the Department of Education and Science was giving assistance was given by Mr P. Gordon Walker, Secretary of State for Education and Science. The institutions receiving assistance are: Glasshouse Crops Research Institute; Pest Infestation Laboratory; National Vegetable Research Station; Rothamsted Experimental Station; Virus Research Unit; Agricultural Research Council, Monkswood Experimental Station; Department of Zoology, Cambridge University; Department of Zoology and Applied Entomology, Imperial College of Science and Technology; Department of Agriculture, Leeds University; Haughley Research Farm; and Insect Pathology Unit. (Written answer, February 6.)



A mosaic of cloud pictures on Mercator's projection, produced by computer from ESSA 3 satellite photographs.

NEWS AND VIEWS

How Useful are Weather Satellites?

THE recent publication of a technical note on "The Use of Satellite Pictures in Weather Analysis and Forecasting" is an opportune moment to ask how useful weather satellites are proving to be. The purpose of the note, published by the World Meteorological Organization, is to help with the interpretation of pictures of cloud formations.

TIROS 1, launched in 1960, was the first satellite designed specifically for meteorological observations. It was followed by a series of TIROS and NIMBUS satellites which tested different camera systems and developed the techniques needed for an operational weather watching system. Once the development work was completed, the running of the project in the United States was transferred from the National Aeronautics and Space Administration to the Environmental Science Services Administration. The first satellite in the operational system was ESSA 1, launched early in 1966.

Weather satellites are used extensively in Britain as an aid in the plotting of weather charts. At present between 20 and 25 pictures a day are received by the Meteorological Office at Bracknell from NIMBUS 2—one of the research and development satellites still functioning—and from ESSA 6. The ESSA satellite has an automatic picture transmission facility, which means that any station in the line of sight can in principle receive pictures of conditions in the area. The forecasters at Bracknell thus have available pictures of cloud formations over large areas of the North Atlantic and Europe, sometimes only 20 minutes after they were taken.

The satellite pictures are used to correct the surface charts—the familiar maps showing the positions of fronts and isobars delineating regions of high and low pressure. The procedure is to compare the cloud distribution implied by the surface chart with that revealed by the satellite pictures. Where the two differ, a correction is made to the surface chart. Pictures of the cloud cover can also be taken during the night with infrared sensors. Such an instrument is fitted to ESSA 6 but has not worked for some time.

It is clear that weather satellites do not eliminate the need for ground observing stations. This is particularly so because there seems to be no immediate prospect of developing satellite-borne instruments for measuring pressures and wind speeds in the lower atmosphere—two parameters of great importance to forecasters. As far as meteorologists are concerned, the full benefits of earth satellites have yet to be realized. Before any really revolutionary improvements in weather forecasting are made, there will have to be many more weather stations, particularly in remote polar and oceanic areas and in the underdeveloped nations. These regions still account for enormous areas of uncertainty on the surface charts.

In addition to stations on land and fixed to buoys at sea, there are plans for the introduction of free-floating balloons to carry instruments over remote regions. Experiments with balloons of long lifetime have been made by the French space agency and by the National Centre for Atmospheric Research, Colorado. The Americans have released a series of 'Mylar' plastic balloons from New Zealand and from McMurdo Sound in the Antarctic. The balloons float at a height where the atmospheric pressure is equal to the pressure inside the balloon. Most of the American balloons were inflated so as to drift at levels between 18,000 feet and 40,000 feet. Some of them have lasted for more than two hundred days, circumnavigating the earth several times until lost because of icing. To test the satellite data collection aspects of this project, the satellite NIMBUS B is to be launched in April. This will be able to locate and interrogate free-floating balloons and relay the information to ground stations. In the first instance tests will be made with a balloon drifting over the United States. It therefore seems probable that in the 1970s, communication satellites will be the chief contribution of space technology to meteorology.

Cerebral Impasse

from our Neurophysiology Correspondent

UNDER the title "The Logical Analysis of Cerebral Functions" a meeting was held at the Royal Society on February 8 under the organization of Professors J. Z. Young and H. C. Longuet-Higgins.

Professor Weiskrantz began his paper with a plea for illogicality in research. This at first seemed at variance with the spirit of the meeting, but he proceeded to give a logical analysis of the effects of temporal lobe lesions on the classification of visual information by monkeys and man. His thesis that engineering analogies often die while the real nervous system survives carries some weight, although a distinction should be made between a logical function and the device which performs it. It is fashionable to compare retrieval by the cerebral cortex with holography and information storage. This is a useful analogy because it presents in tangible terms a system capable of performing some of the more mysterious operations of the brain it is not, of course, suggested that the brain is a hologram but merely that transformation of input into some kind of storable interference pattern is a possible mechanism of memory.

Professor Longuet-Higgins presented his theory of the temporal storage of patterns by "holophony" (*Nature*, **217**, 104). He showed that a bank of resonators could store information about the component frequencies of an auditory input and then reproduce the whole input when stimulated again by only a fragment of it, provided that the coupling constant of each resonator were altered proportionally to the power of the input signal in its frequency band. After his presentation the inventor of holography, who was sitting in the front row, declared that he had been so impressed with Professor Longuet-Higgins's idea that he had been forced to devise alternative models (Gabor, *Nature*, **217**, 585) One of these has the further property that its input and output signals can be expressed in digital terms, the model therefore corresponds to the celebrated "McCulloch–Pitts" neurones Both models are interesting attempts to supply mechanisms for the recall of extended temporal patterns such as the muscular movements made in playing a piece of music

What constitutes information storage in the brain ? Most of those interested in cerebral function favour a change in the conductance of cortical synapses, but this has proved extraordinarily difficult to demonstrate Professor Burns described the results obtained by himself and his colleagues Bliss and Uttley from isolated slabs of cat's cerebral cortex Two stimulating electrodes, one in the white matter and one on the cortical surface, were used to provide two "independent" pathways of excitation to a cell whose activity was recorded by an extracellular microelectrode The effects of stimulation by one path (x) were tested by stimulation via the other (y), measured as the probability that the cell would fire in response to each stimulus pulse A somewhat cabbalistic equation

$$(\mathrm{k}\Delta c = -0\ 50\frac{\Delta x}{x} + 0\ 12\frac{\Delta y}{y} - 0\ 38\ \frac{xy}{y}$$

where c is conductance of the cell to information and the other parameters are as defined) was said to describe the changes observed in 19 of the 26 neurones observed The equation became somewhat less mystical when we were told that the various coefficients in fact had at least 50 per cent uncertainties in either direction Notwithstanding, the main conclusion—that cortical pathways in the cat are not usually facilitated by frequent usage but are in fact de-facilitated—is indeed of great importance, if confirmed, it will be the first direct measurement of changes, apparently at the synaptic level, related to usage in the cerebral cortex One important gap in this paper was the apparent failure to consider factors such as accommodation and fatigue which might have affected the results in a systematic way

Dr Cragg, in collaboration with Dr Rose, has been investigating by light deprivation the anatomy of the rat's visual cortex in the hope of finding anatomical correlates of disuse His results, which have been presented in detail already (*Nature*, **215**, 251), were impressively ordered and carefully analysed, they showed that light deprivation led to an increase in size but a decrease in number of synaptic terminals A first period of exposure to light had the opposite effect

No meeting of this sort would be complete without a computer simulation Dr Thorne, from the Department of Machine Intelligence at Edinburgh, acted as an entertaining representative of the computer in question, describing a programme (10,000 characters in ATLAS autocode) which simulates the way in which a human undertakes the syntactical analysis of English sentences Its novel features are the lack of a comprehensive dictionary, and the relative speed with which sentences are analysed at only one reading Psycholinguistics has given a great impetus to the partitioning of brain mechanisms into those which are inborn and those which are learnt One of its most interesting conclusions is that there are syntactic universals which must be genetically determined—the "deep structure" of language—and which make it possible for a human to select from the infinite possibilities of his language

The meeting in sum was rather disappointing and little new information was produced But all present must have been impressed with the fascination which the problems of cerebral function exert on many scientists from a wide range of disciplines There is a widespread feeling that brain mechanisms will be for the next few decades what molecular biology has been for the last few

Lipid Peroxides

In suitable conditions, unsaturated fatty acids will react with oxygen to form lipid peroxides These compounds have been found in animals in states of vitamin E deficiency, and after exposure of animals to carbon tetrachloride, ultraviolet light and ionizing radiation They are thought to be responsible for at least some of the toxic effects produced by these agents

Lipid peroxides can act as oxidizing agents, probably through a free radical intermediate They readily oxidize small molecules containing the thiol (SH) group, and it was thought that the effects of lipid peroxides might partly be explained by the oxidation of protein SH groups Little and O'Brien have recently examined the oxidation of protein SH groups by linoleic acid hydroperoxide, and have shown that the presence of haem groups affects the reaction (*Biochem J*, **106**, 419, 1968) Haem groups catalysed the reaction so that haem proteins were oxidized more quickly than small thiols, which reacted more rapidly than non-haem proteins The rate of reaction was always greater with the fatty acid peroxide than with hydrogen peroxide, but fewer thiol groups were oxidized per mole of fatty acid peroxide in haem proteins than in small thiols In non-haem proteins there was relatively little thiol oxidation of the native protein by the lipid peroxide, but the denatured protein was oxidized by the lipid peroxide to the same extent as by hydrogen peroxide The addition of haematin to solutions of glutathione (GSH) decreased the amount of SH oxidation It therefore seems that the group most susceptible to lipid peroxide is the haem group, and the presence of haem groups can protect protein thiols from oxidation, but increase the rate of oxidation

Thiols can also affect the formation of lipid peroxides Oxidized glutathione (GSSG) and mixtures of GSSG and GSH will stimulate lipid peroxidation, but Christopherson (*Biochem J*, **106**, 515, 1968) has now shown that GSH actually inhibits ascorbate-stimulated peroxidation in fresh preparations but not in boiled ones Cysteamine and diethyldithiocarbamate inhibited both fresh and boiled preparations, but thioglycollate and 2-mercaptoethanol had no inhibitory effect Cysteine and homocysteine stimulated peroxidation even in the absence of ascorbate, probably because they always contained some oxidized thiol The GSH inhibition does not seem to involve the protection of protein thiols, as the same effects were observed when the preparations had been pre-treated with N-ethyl maleimide, which blocks SH groups

Slater (*Biochem J*, **106**, 155, 1968) has found that the peroxidation produced by carbon tetrachloride can be inhibited by concentrations of promethazine (a tranquillizing drug) which are likely to be found during treatment The same drug strongly inhibited a peroxidation system requiring reduced nicotinamide adenine dinucleotide phosphate, adenine diphosphate and ferrous ions both *in vitro* and *in vivo* Other phenothiazine drugs inhibited this system *in vitro*, but not all compounds which protect against carbon tetrachloride necrosis were inhibitory The author suggests that the inhibition of this system involving free radicals may mean that the phenothiazines can act as general free radical scavengers

Dismantling the Ribosome

from our Molecular Biology Correspondent

Remarkably little is known about the manner in which the ribosome carries out its catalytic function Recently, however, attempts at partial disruption of the structure and reassembly have met with success and it has been found possible to identify certain proteins or groups of proteins with particular aspects of the activity This represents a chink of light in what was until then almost total darkness The same approach has now been taken several steps further by Nomura and his colleagues (Traub *et al*, *Proc US Nat Acad Sci*, **58**, 2430, 1967)

It had already been established that 50*S* and 30*S* particles from *E coli* can be stripped of part of their protein at high concentrations of caesium chloride to yield "cores" 40*S* and 23*S* These cores were inactive, but could be restored to full viability by the addition of the abstracted proteins It was further found that these proteins could be fractionated and the different fractions returned to the cores with varying results Thus the proteins taken from the 30*S* particles in caesium chloride were separated into two groups—one acid (*A*) and one basic (*B*) When proteins of the first group were added to the cores, these remained inactive, but proteins of the second group were sufficient in themselves to restore much of the activity Some or all of these proteins are therefore indispensable

The complete fractionation of the *B* proteins has now been achieved by the use of a new system of column chromatography on phosphocellulose to give five apparently homogeneous components The five proteins have been restored to the 23*S* cores, individually and in combination, and all facets of the activity have been assayed—poly-U-stimulated phenylalanine and viral RNA-stimulated valine incorporation, binding of phenylalanyl-*t*RNA, binding formylmethionyl-*t*RNA in the presence of viral (*f*2) RNA and binding of poly-U When all five β proteins were added to the cores, all activities were restored in full, but omission of either B_3 or B_5 resulted in essentially complete inactivity, except in regard to poly-U binding (which, as the authors point out, could be at least partly non-specific) The lack of B_1 leads to low levels of activity, that of B_2 to moderately high levels, especially in terms of *t*RNA binding Here, however, the authors add the caveat that the cores contain proteins of the same electrophoretic mobility as B_1 and B_2, and if these should in fact be residual B_1 and B_2, these last results are not quantitatively significant The absence of B_4 led to unimpaired, indeed enhanced, activity in all respects except the binding of formylmethionyl-*t*RNA which was reduced by some 60 per cent

Thus at least two essential factors for protein synthesis, B_3 and B_5, have been identified, as well as another, B_4, which is not involved in incorporation, but may well be specifically concerned in chain initiation Studies on the interaction of these proteins with the various elements of protein synthesis hold the promise of momentous results

Further interesting experiments concerning chain initiation come from Ghosh and Khorana (*ibid*, 2455) These are among the dividends of the synthesis of polynucleotides of repeating sequences in the same laboratory, and they provide a pleasing proof of the mechanism previously outlined by Nomura, whereby the 30*S* particle is self-sufficient for chain initiation, whereas the 50*S* component is required for propagation In the presence of the polymers poly-*r*AUG or poly-*r*UG, which contain repeating codons for methionine, the chain initiator formylmethionyl-*t*RNA will bind to the 30*S* sub-unit, while methionyl-*t*RNA and other *t*RNAs will not do so This then defines the chain initiation step If now 50*S* particles are added, the methionyl-*t*RNA is taken up, and a complex containing the two different *t*RNAs can be isolated On addition of the cell supernatant, the dipeptide formyl-methionylmethione is produced There are thus two *t*RNA binding sites on the 70*S* ribosome, the second of which is generated when the two sub-units associate, when this occurs the process of polypeptide synthesis is set in train This adds particular attraction to the notion that the B_4 protein may be identified as part of the initiation site on the 30*S* particle

Viruses and Cancer

Professor M G P Stoker and his colleagues at the University of Glasgow have been concerned with the early events in the transformation of cells into tumour cells, using in particular the polyoma and *SV*40 viruses These viruses have not been found to cause tumours under natural conditions, but are useful tools in laboratory systems using tissue cultures On February 6, Professor Stoker gave a fascinating lecture on the subject to a large and attentive audience at the Royal Veterinary College, Camden Town

When cells are infected with transforming virus two things may happen either the virus multiplies within the cells which then die, or else the normal cells are transformed into tumour cells—Professor Stoker described the several differences that exist between the normal and transformed cells The most exciting part of his lecture, however, concerned the work that several laboratories have undertaken to discover exactly what the transforming virus does inside the cell The great problem is that once transformation has occurred, the causative virus usually disappears without a trace Two antigens—the transplantation and T antigens—have, however, been recognized in these cells, and viral *m*RNA has also been demonstrated It is also expected that techniques will be improved sufficiently to allow viral DNA to be detected—technically a difficult task

But if viral genetic material is in the cell, where precisely is it? As Professor Stoker explained, the fact that transformed cells perpetuate themselves suggests that the division of the virus is in some way associated with the division of the cell Recent work has suggested that loss of the cell chromosome results in loss of transformation, indicating that the viral nucleic acid is possibly integrated with the host cell chromosome.

It seems that the events occurring in a transformed cell are similar to the early stages of vegetative growth of viruses, but that the late functions such as viral replication and synthesis of viral protein do not take place. Why should this be so, and why are the transformed cells not killed? Two alternative explanations have been offered: either the virus is defective when it enters the cell, or else it may be that the transformed cell is unable to synthesize the late products of the virus. By fusing a cell transformed with *SV40* with a susceptible cell, research workers at the Salk Institute at La Jolla and at the Wistar Institute in Philadelphia have shown that virus synthesis begins and the cycle is completed. This suggests that there is no defect, at least not in the *SV40* virus.

Certain requirements for transformation can now be defined. These are a functional virus particle, the absence of cell death, integration of the viral DNA so that it is perpetuated, and absence of the late gene functions of the virus. But do the physiological changes in the transformed cell depend on viral DNA being permanently integrated into the host chromosome, thereby creating the switch that alters regulation, or is the change caused by a viral product which functions irrespective of the position in the cell of the virus DNA? To determine which of these is correct, Professor Stoker has made use of a phenomenon called anchorage dependence in *BHK*21 cells infected with polyoma virus. When these cells were put into agar with transforming virus, only 1–5 per cent were transformed. When, however, a viscous solution of 'Methacel' was used, a third to a half of the cells appeared to have been transformed—that is, these cells could now form colonies in the 'Methacel'. When removed and cultured further, it was found that the majority reverted to normal.

From this Professor Stoker concludes that transformation can either be temporary (in which case the cells become normal again when the virus is lost) or else permanent transformation can occur, in which the viral DNA is integrated. He suggests that although the physiology of the transformed cell does not depend on integration, transformation can only be perpetuated if the viral DNA is integrated. When polyoma virus enters any cell in which it functions, the cell is probably transformed into a tumour cell. Subsequently, the cell may die accompanied by growth of the virus, or else it may continue for a short time as a transformed cell until the virus is lost and is not therefore tagged on to cell replication. Finally, the virus DNA may be integrated, and thereby the transformed characteristics are perpetuated indefinitely, resulting in cancer.

5′ Terminus of R17 RNA

from our Cell Biology Correspondent

MESSENGER RNA is translated in the 5′ to 3′ direction, and the nucleotide sequence of the 5′ terminal region of *m*RNA molecules probably specifies both the binding site for ribosomes and the initiation of in-phase translation. The simplest expectation would be that an initiator codon, either AUG or GUG, is 5′ terminal and fulfils both these functions. Unfortunately, determination of the 5′ sequence of *m*RNA, or of any other RNA molecule, is in practice extremely difficult. First, the only *m*RNA molecules which can readily be isolated in sufficient purity and quantity to warrant such analysis are RNA phage genomes. Second, and more generally important, the ideal method for determining 5′ termini is by specifically labelling the 5′ terminal nucleotide of non-radioactive RNA and then isolating the labelled nucleotide. But, as Takanami (1966, 1967) has discovered, this is difficult without at the same time causing the degradation of the RNA molecules—and every breakage generates a spurious 5′ terminus.

Takanami found that *f*2 phage RNA had to be treated with alkaline phosphatase before it could be labelled with ^{32}P phosphate by the agency of the enzyme polynucleotide kinase, and it appears to be impossible completely to free these enzymes of ribonuclease so that some molecules are always degraded. Takanami's results have, however, one important implication—the 5′—OH group of the terminal nucleoside of *f*2 RNA made *in vivo* is phosphorylated and probably triphosphorylated, *pppXp*. Such termini might have been expected, because RNA chains grow 5′ to 3′ by the nucleophilic attack of the 3′—OH group on the growing polynucleotide on the 5′ α phosphate of the incoming nucleoside triphosphate. Not all RNA molecules possess 5′ triphosphate termini, however; Takanami claims that *E. coli* ribosomal RNA has 5′ phosphoryl termini, *pXpXp*.

The occurrence of the 5′ triphosphate group suggests an alternative approach to the determination of the 5′ nucleotide of RNA. If ^{32}P-labelled phage RNA grown *in vivo* has a 5′ triphosphate, alkaline hydrolysis of such RNA should uniquely liberate the 5′ terminal base as the tetraphosphate *pppXp*. Roblin (*J. Mol. Biol.*, **31**, 51, 1968) in some very carefully executed experiments has shown that alkaline hydrolysis of R17 RNA in fact yields *pppGp*, so that the 5′ terminus must be *pppGpX pY*. He has also shown (doctoral thesis, Harvard University) that the second base is a purine and the third a pyrimidine. This means that neither AUG nor GUG initiating codons are 5′ terminal, and so at least the first three bases must have some function other than initiating polypeptide synthesis. Likewise the last eleven bases at the 3′ terminus of phage RNA do not include a chain-terminating codon (see *Nature*, **217**, 311, 1968). In collaboration with J. T. August, Roblin (doctoral thesis, Harvard University) has also shown that the 5′ terminus of *Qβ* RNA made *in vitro* is *pppGpGpXpYp* where *X* is a purine and *Y* is a pyrimidine.

It now seems likely that all the RNA phage genomes have *pppGp* at the 5′ terminus. Dahlberg (quoted in Roblin's thesis) has apparently found this for *f*2, and both *Qβ* minus and plus strands begin *pppGp* (Banerjee *et al.*, 1967; Bishop, Pace and Spiegelman, 1967). Moreover, Maitra and Hurwitz (1965) showed the predominant 5′ termini of RNA made *in vitro* by *E. coli* RNA polymerase to begin either with *pppAp* or *pppGp*.

Why do purines predominate at the 5′ terminus of *m*RNA, and what is the effect of the 5′ triphosphate group on ribosome binding and the coding properties of these molecules? It should be possible to answer these questions as more and longer 5′ terminal sequences are determined.

Diversification at Harwell

by
JOHN MADDOX

It is now three years since the programme of diversification began at Harwell. How well is it working?

THE Atomic Energy Research Establishment at Harwell is now just over two decades old, and one of the most surprising of the signs of its maturity is that buildings which were within living memory freshly painted and a little stark are now softened by vegetation—a great many trees, ivy on some buildings and Berkshire grass everywhere Indeed, there is occasionally a suspicion that the research establishment may sink back into the landscape on which it was imposed and this, of course, chimes in well with the trough in the morale of the laboratory in the past few years when it has been hard to see just how the laboratory could justify its continued existence It is true, of course that even before the passage of the Science and Technology Act in March 1965 the laboratory had taken the lead among government establishments in planning to engage in research and development of wider interest to civilian industry than the mere development of nuclear power stations Now, looking back, the people at Harwell say that many of them were always frustrated by the need to stick to their narrow brief In any case, Section 4 of the Science and Technology Act gave the Atomic Energy Authority a licence to carry out other kinds of research and development by agreement with the Minister of Technology

Since then, diversification has been the watchword at Harwell For one thing, it seems to be the best way of giving the laboratory a continuing programme of work The fact that Dr Walter Marshall, who will succeed Dr Robert Spence as Director on April 1, has been the principal architect of the diversification programme is one sign of the importance attached to diversification But the programme being followed at Harwell is clearly regarded as a model by other government establishments anxious to find ways of cushioning the effects of financial stringency within the defence budget and even, sometimes, as the Minister of Technology would wish, to make a contribution to the health of British industry It is therefore of some importance to know how well diversification at Harwell is proceeding even though it is necessarily far too soon for anybody to make a final judgment 1970 will be the time for that

It is only sensible to acknowledge that opinions about the potential merits of the attempt to diversify the interests of a government laboratory are varied and often in conflict with those of the research establishment itself There are some, for example, who say that civil servants and quasi civil servants are necessarily less efficient than scientists and engineers who work in industry, but this is not a very serious argument, Harwell indeed has a splendid reputation for getting things done

A more cogent objection is that there must be doubt about the efficacy of programmes of research and development which are pursued at locations different from those at which good ideas are turned into manufactured products. If the people responsible for research and development are separate from the manufacturing organization, so the argument goes, there is a danger that unrealistic programmes will be designed and followed in the research laboratories. Another view is that the separation between research and production loses what may be the most valuable function of industrial research—that of providing a means by which the manufacturing process can be leavened by the spirit of the research laboratories To some people, these potential snags far outweigh the potential advantages of the admittedly magnificent resources which are available at Harwell and, to a lesser extent, at other government laboratories. Even in a preliminary assessment of the diversification programme, these are the most conspicuous questions

Projects now under way, which account for roughly 18 per cent of the research effort at the establishment, include several about which there can be no argument. Harwell is able to use its resources for providing some services to industry which could not easily be accommodated within the manufacturing companies most directly concerned Thus the Non-Destructive Testing Centre under Mr R S Sharpe seems to have a flourishing business in the design and construction of devices for special tasks in engineering industries In the nature of things, the company which commissions the design of such an instrument (paying a fee calculated on the basis of the time and materials consumed) is likely to find that its needs are satisfied for several years. In this sense, the establishment at Harwell functions exactly as if it were an independent profit-making research laboratory. Its advantages are that it can call on the services of a large and skilled engineering organization so that the design of a new instrument can benefit from what may seem to be an ideal matching of need and skill

In much the same way the diversification group at Harwell which is known as the Heat Transfer Service is carrying out work for chemical engineering companies on a fee-paying basis This same group of people, which hopes to exploit the ease with which it has access to computers and the other facilities of Harwell, plans, for example, to offer to chemical engineering companies what it calls a design information service as part of which, for a fee of £1,000 a year, a company will receive half a dozen or more detailed reports on particular pieces of design work which have been carried out The Heat Transfer Service confidently hopes to find between 30 and 50 customers It expects that something like seven people will support a turnover of about £100,000 a year and will have time and energy to spare for a programme of supporting research.

A part of the philosophy which has so far been developed at Harwell is that a research programme of some kind is an indispensable accompaniment of *ad hoc* help to industry Thus a good deal of the effort of the Non-Destructive Testing Centre is concerned with more long-term problems —the development of means of testing the strength of bonds made with adhesives between different materials and the development of means for understanding and then predicting the strength of composite materials such as those made from carbon fibres now coming into fashion

The programmes of research and development in which the establishment has a formal agreement on collaboration with some industrial companies are somewhat different in flavour even if the difference is merely one of degree By now the establishment has accumulated a number of schemes like this Probably the oldest of them are those which form a part of the programme of desalination research on which £1 3 million has been spent in the past three years and to which a further £4 million has just been allocated by the Ministry of Technology In its work on flash distillation, for example, the establishment at Harwell is linked with the Weir Westgarth Company, and there seems to have grown up a tidy division of labour between the two partners Harwell claims, and the company confirms, that the AEA provides a valuable service in carrying out rapid and accurate assessments (by computer) of designs which the company would like to submit for tender One product of this work has been that the company has taken seriously to experimenting with arrangements other than horizontal evaporator tubes in its distillation plants—a potentially important source of economy in commercial operation In practice, the desalination programme is based at Risley in Lancashire, and Harwell tends to contribute the basic research but only part of the large-scale chemical engineering design

The establishment is also deeply engaged in a programme of collaborative research which already involves the Royal Aircraft Establishment at Farnborough, the National Research Development Corporation and commercial companies of various kinds on the development of composite materials based on carbon fibres. The object here is somehow to exploit the high specific modulus of thin filaments of carbon The establishment at Harwell has experience in the development of graphite for nuclear reactors and it so happens that the same equipment can be used for the development on a small scale of methods for manufacturing carbon fibres from long lengths of a synthetic polymer Carbon fibres some hundreds of feet long have been manufactured in this way and bonded together with various resins Heat treatment is known to be a crucial part of the process of developing the full strength of the material as it is in the preparation of graphite for nuclear reactors, and a brief sight of the equipment in use is a sufficient justification of the establishment's claim that in this respect its facilities are unique

In the industrial development of materials based on carbon fibres, funds are provided partly by the National Research Development Corporation In other agreements it has made, the Harwell establishment has found itself in partnership with a straightforward commercial enterprise Thus, for example, there is a collaborative programme of research on the development of means of using ion beams in the construction of semi-conducting electronic devices In this and other agreements, the commitment of resources is said by both partners to be the only real means of knowing that the other is prepared to take the work seriously

The management at Harwell considers that the proportion of the laboratory's effort devoted to work of an industrial character may eventually rise to 25 per cent The schemes now being considered for approval may indeed mean that the target of about a quarter of the establishment's effort on diversification is reached within the coming year The establishment seems to welcome the prospect that it will then have to pick and choose rather carefully the industrial schemes on which it embarks This is entirely in line with the laboratory's view that competitiveness should determine the way in which it functions in industrial concerns Thus the laboratory takes the view that it is no part of its job to help to support unsuccessful companies or declining industries In this sense, the argument goes, its industrial interests are markedly different from those of the research associations It will do its best to reinforce success

A number of comparatively minor criticisms of the diversification programme are comparatively easy to answer in this context Thus to the complaint that the charges made at Harwell for research or consultancy are too high, the laboratory answers that industry is not in any case sufficiently aware of the real costs of professional research and that, in spite of the cost, the demand for the establishment's services has grown rapidly to the point at which it is now almost an embarrassment

The same line of argument is at least a partial response to the suspicion that a laboratory with the prestige of Harwell might be able to foist impractical ideas on a gullible industry Companies which have played a part in collaborative programmes at Harwell say that some of the ideas put up to them under the terms of the collaboration are indeed more innocent of industrial experience than would be welcome At the same time, the companies concerned seem to find no difficulty in imposing a sense of commercial reality on the joint enterprise Evidently what matters is that both partners are committed in money terms The long-term safeguard is that the partnership between the laboratory and the industry should never be one in which the industrial partner is altogether lacking in capacity for research and development The ideal is that the laboratory and its industrial partner should be complementary in some sense or another

That said, it is important that the laboratory may yet find that its new activities raise problems of an unfamiliar kind Some at Harwell point to the irony of how it has been possible in the past few years to dismantle much of the apparatus necessary to safeguard national secrets only, now, to discover that the problems of administering commercial secrecy are every bit as intricate In practice this means that the laboratory would not, for example, be able to tackle the same problem for two different companies Making sure that one company cannot use Harwell as a means of finding out what its competitors are up to is obviously a crucial matter, and years will no doubt go by before the establishment has been able to establish for itself in this respect the kind of reputation which the great independent research laboratories have built up over the years The problem is specially difficult to handle in circumstances in which the establishment collaborates with several different companies on different aspects of the same problem—water desalination, for example Then it is necessary formally to agree in advance on the exchange of information between the companies about the status of separate parts of the development programme without disclosing detailed design information

Problems affecting the staff of Harwell are likely to assume increasing importance in the years ahead At present, the people engaged on the diversification of work are dealt with as are the other employees of the Atomic Energy Authority and this, of course, is inevitable because it is often hard to predict just who is going to be caught up in some industrial programme and for what proportion of his time The result, however, is that it is comparatively easy for industrial companies to tempt away from Harwell people whom they wish to recruit and on one view, of course, this is nothing to weep about—if the laboratory can inject people from Harwell into British industry as a whole, some of its objectives in diversification will have been achieved. But in the long run it is hard to imagine that the laboratory will be able to keep its present salary structure, even with the degree of flexibility which the autonomy of the Atomic Energy Authority provides, and yet allow its diversification teams to function efficiently That, however, is a problem yet to be faced

It goes without saying that a proof of the success of diversification must also lie in the future These are early days and it is bound to be some time before the establishment at Harwell will be able to demonstrate that a substantial proportion of its diversification projects has been successful (Nobody, of course, would expect them all to be successes) So far, however, the signs are encouraging It remains to be determined how freely the establishment will be able to function in British industry—understandably, its interests so far have been largely concerned with problems more or less related to chemical engineering It is also conceivable that success will take the form of persuading industrial companies to increase their efforts in research and development, so that in the long run Harwell's function will be seen as that of a pump primer But this is a long way in the future For the time being, what seems to matter most is that the venture has begun well and has served already to revive sagging spirits at the laboratory It is perhaps worth remembering that things may have begun so well because of the great prestige and undoubted competence of what is, after all, one of the best institutions of its kind In other words, it does not follow that if diversification works at Harwell, it will also work at other government establishments

Engineers and Scientists in Industry

by

S G HOOKER

Rolls-Royce Limited,
Bristol Division

N KURTI

Clarendon Laboratory,
University of Oxford

The Royal Society arranged two meetings in Oxford last year to discuss the difficulties of persuading scientists and engineers to go into industry In this article the organizers of the meetings make some recommendations for action to help the situation

1 Industry's need for more "qualified scientists and engineers" has been widely discussed and documented during the past few years There are several aspects (*a*) What sort of engineers and scientists does industry want? (*b*) Do the universities turn out people with the right type of training and outlook for industry? (*c*) Why is industry apparently unable to attract good quality people in sufficient numbers? (*d*) What aspects of collaboration between industry and university should be further developed to improve the situation?

2. The Royal Society organized two one-day meetings to discuss these questions Each was attended by a representative group of thirty people from industry, universities and government departments The first discussion, held on March 17, 1967, covered all four topics, while the second, held on July 6, 1967, concentrated on collaboration between industry and university Although no definite conclusions or recommendations have emerged, it was felt that a summary of the views expressed at these two meetings should be given some publicity

3 Having been responsible for the arrangements of the meetings, we decided to produce such a summary It would be impossible to mention in detail all the aspects in a brief article, and so we have picked out those points which seemed to us important or novel, and drew from these our own conclusions This is a personal, idiosyncratic report and so are the recommendations, to ensure that none of the participants should feel in any way bound by what we say we do not attribute remarks and views to named individuals

Industry's Needs

4 No clear pattern emerged from the discussion on the relative numbers of B Scs (or equivalent), M Scs (or equivalent) and Ph Ds wanted by industry This is not surprising, because the participants were drawn from many diverse fields including the machine tool, electrical, motor car, aircraft, chemical and pharmaceutical industries All one can say is that, taken as a whole, British industry, as at present constituted, will want at the most 1 per cent of its intake of qualified engineers and scientists at Ph D level, although in some industries, such as electronics and chemical, the figure is much higher

Training Scientists and Engineers for Industry

5 This was probably the most controversial subject in the whole discussion and a gulf was seen to exist between the engineering professors and the industrialists Industry, with its well developed training schemes, has a vested interest in education and this makes the job of the universities difficult Industrialists on the whole regard the three year university courses as sufficient and are in favour of engineers learning their job in industry apart from periodical releases for further training This is in sharp contrast with the practice in many European countries, where universities provide a really full training of engineers lasting five to six years so that further training is not required in industry, except in the firm's specialized techniques

6 Training in industry has the drawback that it often results in narrow specialization and this militates against mobility of manpower Fully trained engineers on the continent settle down quickly in new jobs

It is said, on the other hand, that the "sheltered life" and the type of training in universities tend to make people unwilling or unable to cope with the stresses and strains of industry and to assume responsibilities

Recruitment

7 Industry does not get high quality people in sufficient numbers, and in the view of industrialists too high a proportion of the good graduates remain in the universities after their first degree, either to take advanced courses or to read for a Ph D It was pointed out, however, that one year advanced courses are in many cases a continuation of the undergraduate courses and could be regarded as a tacit acknowledgment of the fact that it is not possible to train a competent scientist or engineer in three years

8 The high proportion of those reading for a Ph D is quite another matter Too many Ph Ds, especially in chemistry and physics, stay on in universities, most of them in the so-called "penumbra" without permanent positions The longer they stay on, the less likely becomes their ultimate assimilation in industry even if industry could offer sufficient numbers of attractive openings for all Ph Ds Many felt that either the number of research studentships should be reduced, or at least more of them should be channelled into research of ultimate benefit to industry This is already being done through changes in the grants policy of the Science Research Council (SRC), for example, the institution of science and industry awards, industrial studentships, industrial fellowships and the earmarking of a proportion of research studentships for work with an industrial content

9 Why was it that graduates preferred to stay in universities rather than go into industry? One reason put forward was that in their undergraduate years students were "brain-washed" in favour of pure academic work and were left in ignorance of the needs of industry and the intellectual challenge of industrial work Equally important appeared to be the poor image of industry Many recruits felt that their abilities were not fully used, they were not "stretched" and they were not given responsibilities sufficiently early in their career It was mentioned in this connexion that industry in the United States is more compartmentalized than in the United Kingdom and as a result they have more high and well paid posts with responsibilities in only a limited field

10 Higher salaries and better working conditions (for example, longer holidays) would help in recruiting At present salaries in industry up to the age of 30–35 are about the same as in universities At least half of the industrial salaries level out at about £2,500 per annum and less than 10 per cent rise markedly above professorial salaries But even if economic considerations permitted a general raising of individual salaries the advantages would be short-lived, for, because of the "Priestley doctrine" government and university salaries would

follow suit This difficulty does not seem to exist in other countries, for example, in France where industrial salaries are markedly higher than university salaries which in turn are fully at par with those in the United Kingdom

11 In several industries insistence on parity within a grade seems to make salary differentials based on merit or qualification difficult to achieve On the other hand, there seems to be a lack of parity between the "science" and the "arts" men in industry If people on the managerial, advertising, commercial and legal side could expect higher salaries than their "technical" colleagues who prefer to continue creating wealth rather than manipulating it, this tends to discourage engineers and scientists from entering industry

Collaboration between Industry and University

12 *The doctor's degree.* One of the reasons for graduates wanting to stay on in universities is the importance attached to the possession of a doctor's degree This was strongly felt by industrialists, to find out the reasons might be the subject for a sociological study Because, however, this attitude cannot be changed quickly, some other remedies have to be found The obvious solution is for universities to award doctor's degrees for work carried out in industry A survey of most British universities has shown that although purely external degrees are offered only by one or two universities, most others do award Ph Ds provided some residential qualifications (one year in most cases) are satisfied The attitude of universities may be summarized by saying that they do not want to be degree-giving bodies for work carried out entirely outside the university

13. It was generally agreed that the work carried out in several industrial research and development laboratories was fully of the type and standard required for the Ph D degree as at present constituted But it was pointed out very forcibly that the Ph D is basically a preparation for pure research, while industry needed people of the same intellectual calibre but with a mind more attuned to industrial life The question was raised whether it would be possible to award Ph D degrees not only for work leading to new discoveries but also as a recognition of high standards of critical ability and of organizational talent required by industry In this connexion a recent scheme started at the University of Aston is worth mentioning This will have three novel features (i) it will be on applied research carried out in industry and directly related to the operation of the firm; (ii) the research project will be more broadly based, that is in addition to the basic discipline the knowledge of a complementary discipline will be required, for example, an engineering project would have an economics content, a physics project would involve operational research and psychology and so on, and (iii) wherever possible the work will be done by teams and the thesis will be written jointly

14 If more graduates of Ph D calibre were to be drawn into industry the output of research in universities would correspondingly be reduced While it is thought that at least in some disciplines a reduction in the number of Ph D students would not damage university research, it appeared that a reduction in the number of post-doctoral people might be serious

15 *Consulting work by university staff* A survey has shown that all British universities allow their staff to do consulting work in industry and that there are on the whole no serious restrictions on the amount of consulting done or on the earnings It was felt, however, that the attitude was more one of toleration than of encouragement and it was generally agreed that universities should positively encourage their staff to get involved through consultancy, in industrial life For example, successful consulting work should be taken into account together with, or in replacement of, publications when considering promotion

16 It was pointed out that there is still too much "prestige" consulting going on, consultants paying occasional visits to the firm concerned without getting involved in its work It was agreed that for consulting to become an effective bridge between university and industry it must be done properly and the consultant should as far as possible take an active part in certain aspects of the firm's work and even assume responsibility for it

17 There was also general agreement that it was undesirable for a firm to insist on the consultant not to work for any other firm in the same field or a cognate field Insistence on "sole consultancy" is to some extent a reflexion on the scientist's or engineer's professional integrity and is unknown in most other professions, for example, in the legal or financial field Although it would be difficult for universities to forbid their staff to enter into sole consultancy agreements, they should strongly discourage it

18 The small firms with no research and development sections were particularly in need of university consultants and it was pointed out that the British Council—Department of Education and Science publication *Scientific Research in British Universities* provided a good guide for finding them

19 *Industrial staff in universities* The importance of industrialists getting more involved in university life was emphasized This practice is becoming fairly widespread, but at present most visiting professors or readers from industry are only concerned with research and postgraduate training. Industrialists feel that an understanding of the aims and methods of industry should be cultivated early in the student's academic life, and so it seems important that visiting professors should get involved in undergraduate teaching as well This obviously would mean some sacrifice by industry, because the benefits of such involvement would be of a long-term nature On the other hand, universities should pay more than a nominal honorarium to visiting professors from industry, a figure in the range of £500–£1,000 per annum being regarded as reasonable The possibility of using industrial visiting professors as temporary replacements for university staff on sabbatical leave might be explored.

Conclusions and Recommendations

We want to make it clear that the following remarks are based on just two one-day discussions and on some additional bits of information we have picked up, and that we did not have the help of a powerful committee or secretariat to provide detailed information It may well be that some of the actions we are suggesting have already been taken or that some of our premises are no longer valid If this is the case, we apologize

(*A*) Not enough is known about either the actual or the desired composition (B Scs, M Scs and Ph Ds) of industry's present intake We recommend that these data be ascertained and the future policy be examined (paragraph 4) This requires action by the Confederation of British Industries (CBI) and by the Committee on Manpower Resources of the Ministry of Technology and the Department of Education and Science

(*B*) There is a great variety in the ways of training engineers and a divergence of opinion about the relative advantages We recommend that this whole question be examined in depth and that methods in the United Kingdom be compared with continental and American practices (paragraphs 5, 6). This requires action by the Council of Engineering Institutions (CEI), the CBI and the Committee of Vice-Chancellors

The following three conclusions and recommendations are related to industry's recruitment difficulties

(*C*) As a result of the "Priestley doctrine", that is, the insistence on parity between the three sectors, salaries in industry are much the same as those in universities and the Civil Service Within industry salary differentials to recognize higher academic qualifications are small There is also a strong feeling that prospects of promotion for "arts" graduates, most of whom are in the administrative or managerial sections, are better than for engineers or scientists. We recommend that these questions be examined (paragraphs 10, 11). This requires action by HM Treasury, the CBI and the professional institutions (for example, Association of Professional Civil Servants, the Association of University Teachers, and the appropriate trade unions).

(*D*) Given more attractive conditions in industry, recruitment of graduates could be improved by reducing the number of SRC and other studentships and of postdoctoral awards. We recommend that the short-term and long-term effects of such measures on university research be examined (paragraphs 7, 8, 14). This requires action by the research councils, especially the SRC, the Council for Scientific Policy, the Committee of Vice-Chancellors and the Royal Society.

(*E*) The possibility of gaining a doctor's degree on the basis of work (not necessarily of research) done in industry would help recruitment. We recommend that the whole basis of the Ph D degree, which at present is geared to a university career, should be examined (paragraph 12). This requires action by the Committee of Vice-Chancellors, the SRC and the Royal Society.

While the measures mentioned under *C*, *D* and *E* would go a long way towards improving recruitment by industry, they are not sufficient in themselves. It is important that universities, that is, both staff and students, should become more aware of the needs of industry, and that industry should make a more effective and intelligent use of high grade manpower. The following points deal with this question.

(*F*) We recommend that consultancy by university staff both at professor and lecturer level should be positively encouraged by the university authorities (paragraphs 15, 16, 17). This requires action by the Committee of Vice-Chancellors and the CBI.

(*G*) We recommend that part-time university appointments (visiting professorships, fellowships, readerships, lectureships) of industrial staff should be encouraged and that the need for involvement in undergraduate teaching be emphasized (paragraph 19). This requires action by the Committee of Vice-Chancellors and the CBI.

(*H*) We recommend that the dissemination of information already available about university activities of interest to industry (for example, *Scientific Research in British Universities*) should be made more effective (paragraph 18). This requires action by the Office of Scientific and Technical Information, the Ministry of Technology, the CBI and the Committee of Vice-Chancellors.

Multiphase Development of the Lunar Crater Tycho

by
R. G STROM
G. FIELDER*
Lunar and Planetary Laboratory,
University of Arizona

Data collected by Orbiter V when it landed on the Moon in 1967 provide information about the history of the crater Tycho. Volcanic eruptions seem to have been involved in the crater's development

TYCHO, the rayed lunar crater 85 km in diameter, has long been regarded as the classic example of a large impact crater. Its anomalously high radar reflectivity[1] indicates that the floor of Tycho is rougher or denser than the surroundings. Its anomalous thermal behaviour[2] during a lunation, or during eclipse, indicates that the materials of the crater are better thermal conductors than the terrain around Tycho. Taken together with the facts that the rays of Tycho are stratigraphically more recent than most objects which they cross, and that the walls of the crater are sharply sculptured and nearly circular, the observations have been interpreted widely to demonstrate that Tycho is a recent impact structure.

In 1967, Tycho was photographed in medium resolution (Fig 1) by Orbiter V, and much of the floor, wall and surrounding terrain was, in addition, covered by high-resolution photography. Surveyor VII soft-landed and chemically analysed the material in the "continental" domain covered by the high-resolution shots. In this preliminary report we extract information from the Orbiter V coverage of Tycho. We find clear evidence for extensive volcanism in and around Tycho.

Geological Units

The geology of the Tycho region will be described fully when the Surveyor VII analyses are available. On the basis of marked morphological and topographical differences of the terrain immediately north of Tycho, as represented on the Orbiter V photograph *H*–128, we mapped the approximate boundaries (Figs 1 and 2) of the principal geological units in the region. Units *A* and *B* have all the characteristics of lava flows and they cover the units *C* and *D* and so must be later than these units. A high density of fine fractures, shown as short hair lines in Fig. 2, was found principally in units *C* and *D* and was used to define the boundaries of these units, which appear to overlie unit *E*. Unit *E* itself is largely devoid of similar fractures and we believe that it is the oldest geological unit mapped. Fine fractures could, of course, be filled by detritus on the older units, so the paucity of fractures there is in accord with our proposed age sequence.

We believe that units *C* and *D* are volcanic flows: in addition to some parts being fractured in a manner characteristic of lavas, they are topographically higher and are less cratered than unit *E*, also, they conform, largely, to the "deltoids" described[3] as special fracture zones from which lavas were extruded to build up complex plateaux.

Several flow structures have been mapped in addition to those shown in Fig 2. Six well-defined flows occur W. and N W. of Tycho and are shown in Fig 1. They are 3–20 km long and about 2–6 km wide. The direction of flow is indicated by arrows in Fig 1 and conforms to the slope of the terrain on which they have flowed. Several have flowed towards Tycho and others have flowed away from Tycho.

Five of these six flows have apparently issued from craters which have been breached by the flows. Their surface texture is coarse with a wrinkled or ropey appearance and they seem to have been considerably more viscous than the flows in the maria. The general appearance of the flows and the fact that they are associated with craters indicate that they are volcanic flows—probably lava rather than ash or debris flows.

The most distant flow is just over 100 km from the rim of Tycho which is near the limit of the medium resolution coverage of Orbiter V in this area. It is quite possible

---

* On leave from the University of London.

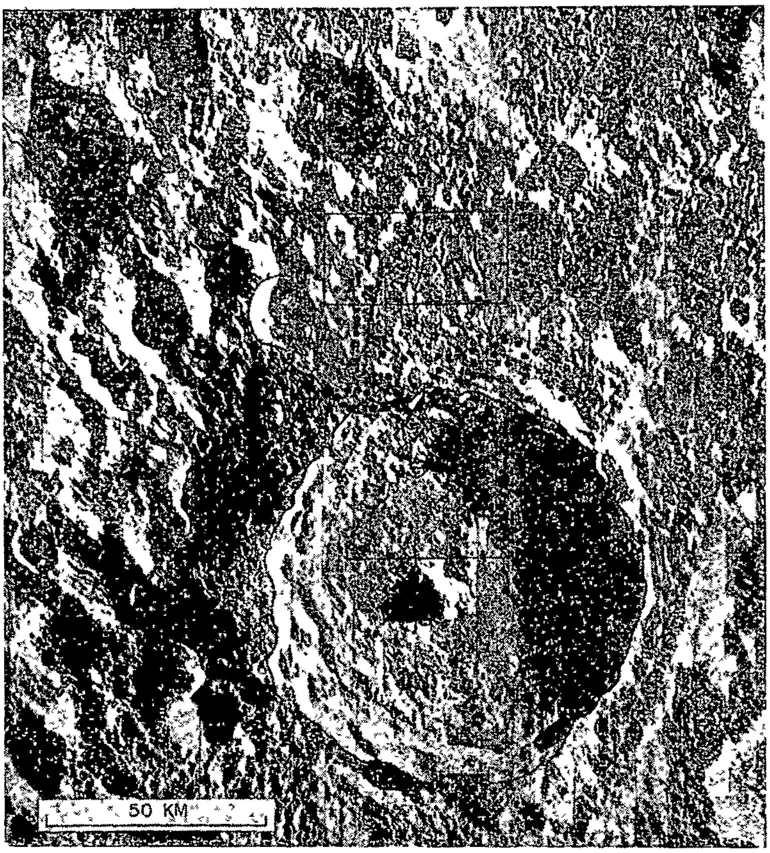

Fig 1 Medium resolution mosaic of three Orbiter V photographs of Tycho and region The rectangle north of Tycho outlines the area mapped in Fig 2 from a high resolution photograph That portion of the floor of Tycho mapped in Fig 3, from another high resolution photograph, is also indicated here The black spots give the approximate locations of those "lakes" on which craters were counted Larger "lakes" are shown in outline, chiefly east of Tycho Finally, the principal lava flows are sketched, and the direction of flow is indicated by arrows (Based on NASA photographs *M* 125, 126, 127)

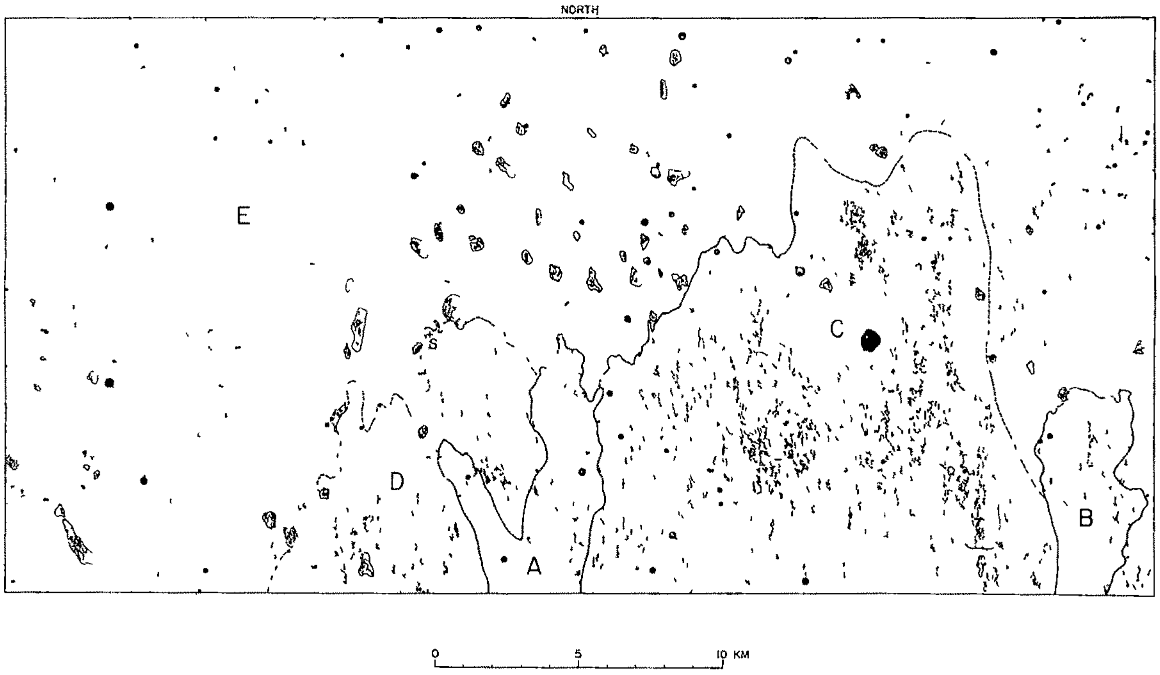

Fig 2 Principal geological units *A* to *F*, discussed in the text Broken lines are used to define boundaries in places where they are only approximately located Short hair lines define fractures The smallest, irregularly shaped units mapped are the lava "lakes" discussed in the text Craters are blacked in The position of Surveyor VII is shown as a cross labelled *S* at the northern extremity of unit *D* (Based on NASA photograph *V*–*H*–128)

that other flows occur at even greater distances. The fresh appearance of these flows, the relatively close proximity to Tycho and their similarity to flows on the rim and on the interior wall of Tycho suggest that they are associated with the formation of Tycho.

The interior slopes of Tycho also show signs of the flow of material (Fig. 1). These are primarily expressed as channels with raised rims, although there are several flows with well-defined fronts. One of these flows has issued on the floor and merged with it so that the floor and flow appear as one textural unit. Peripheral fissures on the floor continue across the flow. Thus the flow reached the floor when it was still in a fluid or plastic condition and before the formation of the peripheral fissures, and the flow must be essentially the same age as the floor. The flow channels have raised rims and several appear to begin at craters on the wall. The channels are almost identical to lava drainage channels with natural levées built up by the overflow of lava. The similarity is strengthened by the fact that several of the channels start at craters and at least one ends in a small "lake" which exhibits a flow front.

Numerous small "lakes" of relatively dark material and exhibiting fine fractures are situated in circular to irregular depressions. They are depicted in Fig. 2 and interrupt the other units (*C*, *D* and *E*), therefore, they must be later than these units. The "lakes" are concentrated within 20 km of the rim and several of the larger ones have distinct fronts where they contact the sides of the depressions in which they lie. The approximate locations of the "lakes" studied on the high resolution frames are shown as filled circles in Fig. 1. The larger "lakes" may be seen only on the medium resolution coverage and their well-defined elevated-fronts are also mapped in Fig. 1. The distribution of these lakes near the rim of Tycho indicates they are intimately associated with its formation. We believe the lakes consist of lava which has found egress to the surface through vents or fractures primarily associated with the depressions in which they lie and that, because of the paucity of craters and abundance of well-defined fractures found on them, they are relatively recent features. Finally, that part of the floor of Tycho recorded on the Orbiter V photograph *H*–125 forms a geological unit which is morphologically quite different from the other units. It is shown in Fig. 3 and is characterized by steep and gentle-sided domes (not mapped) interspersed with terrain which displays a highly fractured and ropy pattern similar to that of terrestrial lava. Several gentle domes exhibit the same texture as the floor and have fissures along their crests. They are probably updomings of the floor or tumuli produced by the hydrostatic pressure of fluid lava underneath the solid crust. Numerous crater chains and craters of highly irregular shape occur on the floor. Some of these features are shown in Fig. 3 and attest to the intense volcanic action to which the floor has been subjected.

A set of peripheral fractures is found on an inward sloping bench at the margins of the floor and indicates that the floor has subsided leaving a higher bench broken by tension fractures in the zone of maximum downbending. These features are very similar to the fractured benches found on terrestrial lava lakes—for example, in Hawaii—caused by the drain-back of lava into the vent. If the Tycho bench formed in a similar manner, then it is probable that Tycho is underlain by a magma chamber into which the lava drained.

Eumorphic (sharp-rimmed) circular craters as large as, or in excess of, 50 m in diameter have been mapped on all the geological units. These craters may be used in an attempt to date the different units.

Crater Counts

To check the stratigraphic sequence suggested by the morphological and topographical relations, we counted probable impact craters on each geological unit mapped. This was done using only eumorphic, circular craters, and corrections for the many shadowed and over-exposed areas were applied for all regions using planimetric and square-counting methods. Although the counts of craters

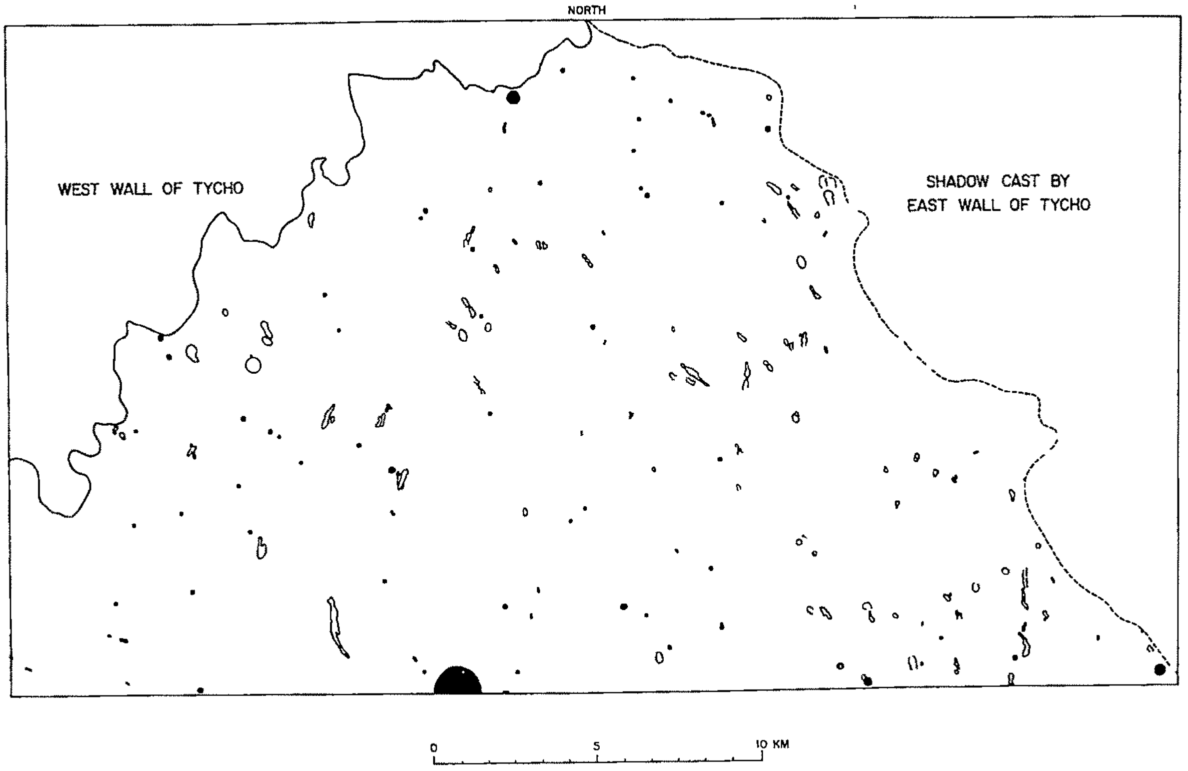

Fig. 3. Sketch of the floor unit discussed in the text. Eumorphic craters are blacked in, whereas probable volcanic craters are shown only in outline. (Based on NASA photograph *V–H*–125.)

on the floor of Tycho are restricted to eumorphic craters, the position of many at the apex of hills and on or at the end of fissures suggests that they may be volcanic rather than impact in origin The count therefore represents a maximum on this unit The measured areas and counts for the different units are given in Table 1

The geological units *A* and *B* are alike and, indeed, are found to have the same crater density, within the limits to be expected from the method Again, the apparently similar units *C* and *D* have similar number-densities of craters A less obvious result of the crater counts is that the "lakes" and the "floor" units are cratered to a similar number-density (Table 1) Unit *E* has 4·5 times as many craters per unit area as the floor of Tycho, 2·6 times as many as unit $(A+B)$ and twice as many as unit $(C+D)$

It would be natural to interpret these differences in crater density as age differences between the various geological units Random fluctuations (such as might have resulted from "secondary" cratering) in crater density as a possible cause of the observed differences can be ruled out because of (*a*) the extent of the areas mapped and (*b*) the similarity in the cratering on superficially similar geological units With the assumption that cratering is related to age, *E* would be the oldest unit mapped while the floor of Tycho and the lava lakes would be the most recently formed units The counts completely confirm the observed stratigraphic relations of the various geological units

A further analysis of the number data will now be given In Fig 4, the data are represented logarithmically as cumulative numbers per 1,000 km² of surface against minimum crater diameter The most significant points are joined with continuous lines, the less significant points with broken lines. Because the difference in crater density of units $(A+B)$ and $(C+D)$ was only 1·3 at the 50 m size (Table 1), we took sample counts in these regions for craters down to half that size (Fig 4) to see if the same difference persisted The result shows a similar difference in crater density, although we suspect that there is observational incompleteness in the counts of the smallest craters because the terrains are rough and the graphs bend inward relative to the graph for the "lakes", where equally small craters (25 m) were seen easily.

The fact that $(A+B)$ is actually younger than $(C+D)$ comes from stratigraphic evidence By themselves, the crater counts are insufficient to establish the age difference beyond doubt, although they do not conflict with the geological information Random fluctuations in crater density may be expected to render the counting method of dating invalid for small areas. Even when areas *A*, *B*, *C* and *D* are taken separately, however, either of the areas *A* and *B* has fewer craters per unit area than either of the areas *C* and *D* (Table 2); and *A* is adjacent to *C*, *D* and *E*, whereas *B* is adjacent to other parts of *C* and *E* (Fig 2). Thus it is not unlikely that the observed differences in crater density on units $(A+B)$ and $(C+D)$ are a true measure of age

Combining the results of the crater counts with the geological information on the relative age of the different units, we conclude that (*a*) materials of unit $(C+D)$ are appreciably younger than those of unit *E*, (*b*) materials of unit $(A+B)$ are somewhat younger than those of unit $(C+D)$; (*c*) the materials forming the floor of Tycho, and those forming the lakes outside Tycho's walls, are appreciably younger than those of units $(C+D)$ and $(A+B)$, and (*d*) the flow on the wall of Tycho which merges with the floor is the same age as the floor.

Table 1 TOTAL CRATER COUNTS IN DIFFERENT GEOLOGICAL UNITS

Geological unit	Area examined (km²)	Corrected area of count (km²)	Total No of craters greater than 50 m in diameter	Craters per unit area (floor = 1)
Lakes	22	22	17	0·9
Floor	460	400	347	1·0
A	24	19	30	1·8
B	19	15	22	1·7
C	185	136	278	2·4
D	51	42	81	2·2
E	463	342	1,324	4·5

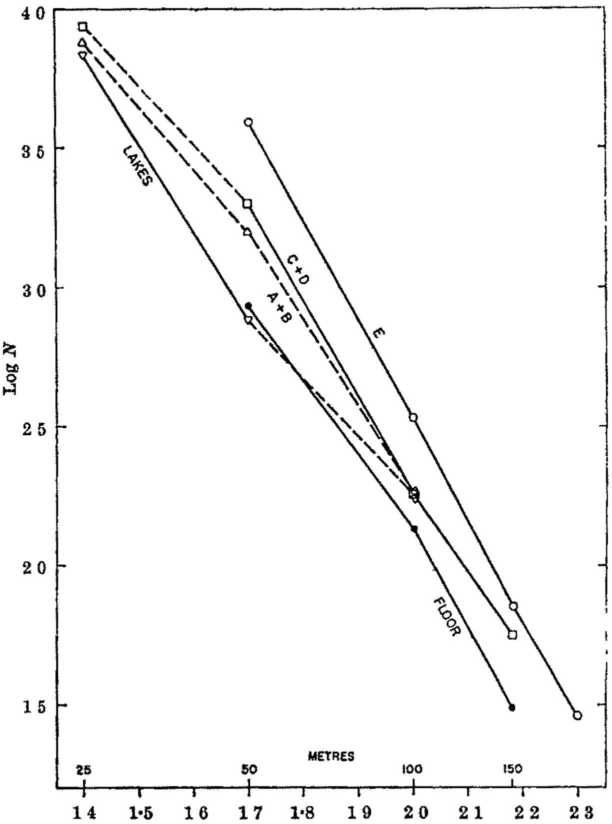

Fig 4 Numbers *N* of craters ≥ Δ metres in diameter/1,000 km² of surface, represented logarithmically for the geological units indicated

Further Implications

If these age differences are accepted, the inevitable conclusion is that at least the terminal phases in the formation of the floor and outer rim of Tycho were protracted Certainly, the rim materials that we now see cannot be ejecta. first, the ejecta blanket of an impact crater would have been formed within minutes and would tend to be uniformly cratered or to show systematic losses of craters as the rim crest was approached; second, it would not display the range and disposition of geological units, or the sharp discontinuities between them, that are observed It seems that the extrusion and flow of lava at very different times is the only way to account for the observations If, however, an impact produced Tycho, lavas might be generated at the time of the impact, as Urey[4] suggested, or later as Hartmann[5] suggested. We now show that neither hypothesis seems to be adequate to account for the present observations

The time interval between the formation of the various lava units is important in this discussion and, given the rate of cratering, the appropriate intervals of time can be calculated. An attempt to date the individual units may be made using Hawkins's[6] influx law $\log N = \log m_\infty - 7·5$, where *N* is the cumulative number of meteorites received by 1 km² of Earth per hour and m_∞ is the mass in kg of a meteorite at infinity. Assuming that the diameter of the meteorite, density 3 g cm^{-3}, required to form a crater of diameter Δ is Δ/15 (see ref 7), it follows that the mass required to form a 50 m crater is $5·8 \times 10^4$ kg. If (as we expect) the meteoroid flux is the same in the vicinity of the Moon, and if it is constant in time, then one would expect one primary lunar impact crater 50 m or more in diameter to be formed per 1,000 km² every

Table 2. INCREMENTAL AND CUMULATIVE CRATER COUNTS IN DIFFERENT GEOLOGICAL UNITS

Geological unit	n* (50–100 m)	N† ($\geq$50 m)
Lakes	580	759
Floor	733	869
A	1,421	1,579
B	1,267	1,467
$A+B$	1,394	1,575
C	1,816	2,044
D	1,881	1,929
$C+D$	1,821	2,005
E	3,529	3,871

* n Number of crater/1,000 km² between 50 m and 100 m in diameter
† N, Total number of craters/1,000 km² $\geq$ 50 m in diameter

Table 3 ESTIMATED AGES OF GEOLOGICAL UNITS

Geological unit	Age in units of 10^8 yr	
Lakes and floor	1 6	0 4
$(A+B)$	3 2	0 8
$(C+D)$	4 0	1 0
E	7 7	2 0

2×10^5 yr Using the cumulative number-data of Table 2, it follows that the various geological units may be expected to have the ages listed in the second column of Table 3

A very crude but independent method of dating the geological units is to consider the volume of lunar material eroded per unit surface per year and to assume that the 50 m craters would no longer be regarded as eumorphic after 4 m of material had been eroded from their rims and deposited in and around them Data, including microphone data, relating to the particle flux in space have been used[8] to arrive at a lunar erosion rate of $<10^{-6}$ cm³ cm⁻² yr⁻¹ Nilsson[9] showed that the microphone counts of particles in space were too high, and certainly unreliable He suggested (private communication) that a better estimate of erosion rate could be deduced from the observed decrease in reflectivity of the Earth-satellite Echo I Assuming that <5 per cent of the surface of the 100 ft balloon was etched by micrometeorites during a 4 yr period, and using the skin thickness of the balloon, $1\ 3 \times 10^{-3}$ cm, to obtain an upper limit for the volume of material eroded, it follows that $<1\ 6 \times 10^{-5}$ cm³ cm⁻² yr⁻¹ was eroded away The 10^{-6} figure indicates that all the 50 m craters counted would be $\lesssim 4\ 0 \times 10^8$ yr old If $2\ 0 \times 10^8$ yr were the absolute age of the average eumorphic craters on unit E, the incremental crater counts in Table 2 would yield the ages listed in column 3 of Table 3 These differ by a factor of 4 from the age estimates based on Hawkins's equation If the estimates are taken at face value, the time span between the formation of the lavas $(A+B)$ and $(C+D)$ is of the order of 10^7 or 10^8 yr The floor of Tycho and the lava lakes solidified $\sim 10^8$ yr later than the lava flows $(A+B)$ The figures quoted are illustrative only, but we stress that, even if the ages are in error by an order of magnitude, there must still be wide intervals of time between the formation of the various lava fields We therefore believe that polycyclic eruptions characterized at least part of the formation of Tycho

Size Changes in Isolated Nuclei of *Amoeba proteus* on Treatment with Polyionic Substances

by

Jagellonian University,
Cracow

J A FORRESTER
K G MOREMAN
E. J. AMBROSE
Chester Beatty Research Institute,
Institute of Cancer Research
Royal Cancer Hospital, Fulham Road,
London

Swelling of nuclei in *Amoeba proteus* is quite independent of the ionic strength of the medium or the osmolarity Rather, it seems that surface charge is important in determining the configuration of a biological membrane which could give rise to large and specific changes in its permeability

SEVERAL authors[1,2] have suggested mechanisms for amoeboid movement which locate the source of locomotory energy in contracting membranes While considering which molecular mechanisms are involved in such contractions, the studies of Kuhn and his collaborators[3] on the interconversion of chemical and mechanical energy in charged polymers led us to wonder whether the cell membrane was behaving in a manner analogous to Kuhn s polyelectrolytes, its degree of extension or contraction being determined by the effective net surface charge density over its surface Experiments performed on intact, moving *Amoeba proteus* and *Naegleria gruberii* will be reported elsewhere We wish to focus attention here on a simpler membrane system, namely, the isolated nucleus of *A proteus* and its response to various polyionic substances

Changes in the volume and size of various isolated organelles—for example, mitochondria[4-6], chloroplasts and microsomes[7] and ribosomes[8]—have often been described, and generally attributed to swelling and shrinking consequent on passage of water across the bounding membrane Experiments with isolated nuclei[9,10], however, suggest that the volume changes that have been observed are induced not by the osmolarity of the suspending medium but by more specific stimuli such as the ionic strength and the presence or absence of certain macromolecules in the solution The nuclear envelope certainly does not constitute an osmotic barrier[9,11], and we considered that in isolation it would provide a useful model for the study of contractile processes in an isolated biological membrane

Amoebae were grown in rice grain cultures in Petri dishes They were removed from such cultures and placed on a glass slide and when they had adhered to it were washed several times in Chalkley's medium Isolated nuclei of *Amoeba* are very sensitive to mechanical injury[12], and puncture of the nuclear membrane with a microneedle leads to a collapse of the nucleus into a shrivelled mass. To avoid such injury, cells were disrupted by the application of an electric field. If two electrodes are dipped into opposite sides of a drop of Chalkley's medium on a slide containing some amoebae and the applied potential is gradually increased by means of a potentiometer, then at a certain value the outer membrane of the cell will be disrupted at several points and the cell contents will rush out into the surrounding medium under the influence of the electrophoretic field. When a nucleus isolated in this manner has been allowed to stick to the slide it can be washed free of other debris by gentle irrigation. Changes in appearance of the nuclei when irrigated with different media were observed by phase contrast at × 400 magnification and changes in size were measured with an ocular micrometer. To avoid mechanical damage no coverslips were used with these preparations.

The nucleus of *A. proteus* has a discoid shape with a rather irregular border when observed in the cell by phase contrast microscopy. During movement, it undergoes some changes in shape. After isolation and washing in Chalkley's medium or in simple salt solutions at *p*H 7·2 (0·14 M and 0·01 M sodium chloride, 0·2 M, 0·01 M and 0·001 M phosphate buffer) nuclei immediately expand and take up a more regular shape. Such nuclei are quite transparent to light and their surfaces seem to be quite smooth and uniform. This swelling phenomenon is quite independent of the ionic strength of the medium or osmolarity, proceeding equally well in distilled water, 0·2 M sodium chloride or 10 per cent sorbitol. Such an expanded nucleus is shown in Fig. 1*A*.

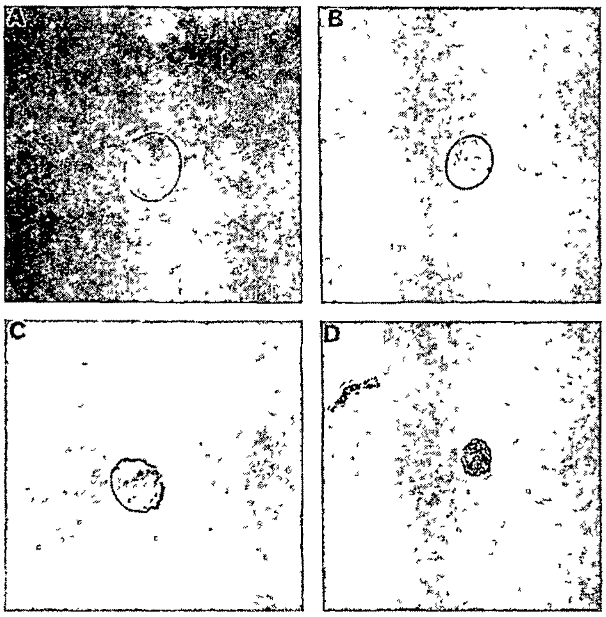

Fig. 1. *A*, Nucleus isolated in 0·14 M sodium chloride, *B*, nucleus in presence of 0·005 per cent poly-L-lysine, *C*, nucleus in presence of 0·1 per cent poly-L-lysine, *D*, nucleus in presence of 0·05 per cent poly-L-lysine.

Poly-L-lysine adsorbs very readily from very dilute solutions (3–5 μg/ml.) onto negatively charged biological membranes as our observations on *N. gruberi* had shown. Irrigation of an isolated nucleus with a 0·05 per cent solution of poly-L-lysine (molecular weight about 50,000) brought about an immediate strong contraction accompanied by changes in appearance of the nucleus. First, the normal intracellular appearance of the nucleus was restored and then further contraction took place within less than a second and a similar effect could be brought about by applying 0·2 per cent protamine, another positively charged polymer. The numerical values observed are given in Table 1, and stages in the contraction are illustrated in Fig. 1*B*, *C* and *D*.

ATP is a tetra-anion and, as might have been predicted on mechanochemical grounds, a 1 mM solution did not stimulate an isolated nucleus to contract. With 1 mM ATP + 1 mM magnesium chloride, however, a very strong contraction was obtained. The surface of the nucleus remained smooth, but the diameter was always much less than inside the cell. This dramatic contraction of the nucleus was specifically dependent on the presence of magnesium ions; substitution of calcium ions gave rise to no measurable contraction.

Nuclei were irrigated with solutions containing 1 mM EDTA, 0·1 per cent heparin or 0·2 per cent sodium polyglutamate, all containing 1 mM magnesium chloride. In all cases a contraction of the nucleus was observed although this was never so strong as in the ATP–magnesium solution. The values which were obtained are recorded in Table 1. All these polyanions in solution without magnesium ions are without effect on isolated, swollen nuclei.

Table 1. EFFECT OF VARIOUS POLYELECTROLYTES ON THE DIAMETER OF ISOLATED NUCLEI OF *A. proteus*

Diameter of nuclei as a percentage of diameter in solution of 0·14 M sodium chloride at *p*H 7·2

Protoplasm	84 ± 5
Medium alone, 0·14 M sodium chloride	100 ± 3
0·2 per cent sodium polyglutamate	101 ± 2
0·1 per cent heparin	104 ± 3
0·1 per cent heparin + 1 mM magnesium chloride	81 ± 5
0·2 per cent protamine	82 ± 4
0·05 per cent poly-L-lysine	77 ± 2
1 mM EDTA + 1 mM magnesium chloride	65 ± 3
1 mM ATP + 1 mM magnesium chloride	58 ± 3

Single nuclei were irrigated with a sequence of the reagents described here applied in various orders. It was found that the appearance and size of nuclei were always determined by the medium bathing the nuclei at the time of observation and bore no relation to their past history. Exceptions to this rule were nuclei which had contracted under the influence of ATP–magnesium or poly-L-lysine which did not recover completely on washing with Chalkley's but which required treatment with polyglutamate or heparin. By treatment of a single isolated nucleus with various media it was possible to follow it through an apparently indefinite number of cycles of expansion and contraction. An example of such an experiment is recorded in Table 2. In Table 3, a similar experiment in the presence of 10 per cent sorbitol shows the independence of the phenomena of osmolarity.

If our analogy with Kuhn's mechanochemical models is correct, change in *p*H and alteration of the degree of ionization of surface groups should also change the configuration of the membrane. Accordingly, nuclei were treated with 0·2 M acetate and phosphate buffers from *p*H 3·6 to 8·0. Fig. 2 represents the mean of results obtained from measurements on ten separate nuclei, the results in each case being expressed as a percentage of the value for the given nucleus at *p*H 8·0. The results show that depression of ionization of acidic groups at low *p*H indeed induced a strong contraction of the nucleus which proved to be quite reversible. There is also the suggestion of a point of inflexion in the curve near to *p*H 5·0 which would suggest that we are not here dealing with the ionization of a single species.

The most commonly accepted molecular theory of contraction is the well known "sliding filament" theory derived from the analysis of the contraction of muscle fibres by light and electron microscopy. It would seem, however, to be only applicable in detail within the relatively complex system of the muscle proteins. Contractile processes in living organisms are not limited to

All reagents were dissolved in 10^{-3} M phosphate buffered saline, *p*H 7 2, containing 10 per cent sorbitol

those of muscles but on the contrary are shown by a variety of structures, so it seems to us that the explanation of these processes should stem from a rather more general theory of molecular behaviour than one designed to cope with one specialized molecular array Such a basis is provided by the mechanochemical principles laid down by Kuhn and Katchalsky and their co-workers[3,13] and we wish to discuss our results in these terms

Molecules of flexible polyelectrolytes change their shape in solution as the mean electrical charge density along their length is altered The change in configuration is brought about by a readjustment in the relation between the forces stemming from the Brownian motion of the molecule tending to bring it to a roughly spherical configuration, a force of entropic origin, and the Coulombic repulsive forces between the charges along its length which tend to extend it The higher the net charge on the molecule the greater will be its extension and asymmetry

In their reaction with hydrogen ions at low *p*H and with polylysine, nuclei of amoebae behave exactly analogously to polyanions in solution, collapsing as their overall surface charge density is reduced It is of considerable interest that three polyanionic materials will induce contraction of the nucleus when in the presence of magnesium ions although they have, as we would have predicted, no effect on their own This result suggests strongly that a mechanism similar to that proposed by Morales[14] for the interaction of ATP and magnesium with myosin is in operation He has suggested that the quadrivalent anion could be bound by ion-triplet bridges, with magnesium being the linking ion to the anionic sites on the myosin molecule, thus reducing its overall charge and causing a contraction as indicated here It is evident from these experiments that anions other than ATP are capable of fulfilling this role

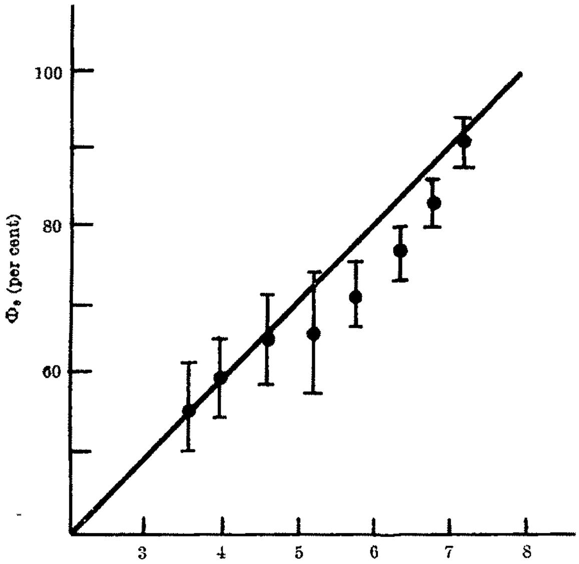

Fig 2 Effect of *p*H on the size of isolated nuclei of *A proteus* Ordinate, diameter expressed as a percentage of the average diameter at *p*H 8, abscissa *p*H of surrounding medium

Davies and Spencer[15] have ascribed the swelling of nuclei in various media containing heparin to competition between heparin and DNA for binding to histone and consequent expansion of negatively charged DNA molecules The experiments described here make this suggestion unlikely, especially because heparin can induce a nuclear contraction in the presence of magnesium ions and they draw attention to the importance of the ionic milieu in which fixation is performed when interpreting light or electron micrographs

Bryn Jones[16] has shown that addition of ATP to tissue culture cells in the presence of magnesium leads to a reduction of adhesiveness which he ascribes to a contraction of the membrane surface as a result of the presence of actomyosin proteins at the surface

Experiments with intact *A proteus* indicate that contractions can be brought about at the periphery of the cell by local application of polylysine to an advancing pseudopodium, which are similar in appearance to the natural tail of the amoeba (Gingle, Korohoda and Wolpert, unpublished) We feel that these experiments show the importance of surface charge in determining the configuration of a biological membrane which could give rise to large and specific changes in its permeability Whether these changes are themselves capable of providing the conversion from chemical to mechanical work or whether they are the initiators of the contraction of actomyosin molecules at or adjacent to the cell surface requires further experimental work to decide

We thank Professor L Wolpert and Mr D Gingle for advice This work was supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research Royal Cancer Hospital) from the Medical Research Council, the British Empire Cancer Campaign for Research and by a Public Health Service research grant from the National Cancer Institute, US Public Health Service

Distribution of Plasma Fatty Acid before and after Canine Hepatic Homograft

by
WILLIAM S WORTH
Department of Pharmacology,
University of Colorado Medical Center,
and
Veterans Administration Hospital,
Denver, Colorado

The effect of liver transplantation on the fatty acids in the plasma of dogs suggests that fat is mobilized and dehydrogenated after the operation

ELUCIDATION of lipid metabolism in the liver transplant recipient has been hampered by the fact that survival rarely exceeded 15 days As surgical techniques improve and prolonged liver transplantation survival becomes imminent, it is increasingly important to look at the physiochemical role of the transplanted liver to determine its capacity for normal metabolic function The liver is primarily involved in lipid metabolism, and so its function may well be reflected in quantitative or qualitative changes in plasma lipid and fatty acid values

The livers of three healthy unrelated mongrel dogs were completely removed and replaced by an orthotopic hepatic homograft obtained from unrelated dogs[1] Azathioprine and antibiotics were administered daily after the operation The diet consisted of commercial dog food freely given Blood from the peripheral venous system of a fasting dog was collected in ethylenediaminetetraacetate (EDTA) pre and post-operatively twice a week for clinical chemistry and lipid analysis Clinical chemistry and liver function tests were performed routinely and are reported elsewhere[1,3]

The "lipid profile", consisting of total, free and esterified cholesterol (CE), phospholipid (PL), non-esterified fatty acid (NEFA) and triglyceride (TG) were analysed by chemical procedures[4-7]

Isolation of the lipid classes was accomplished by extracting the lipids from 1 ml of plasma with chloroform methanol (3 2 v/v) and then spotting the extract on a

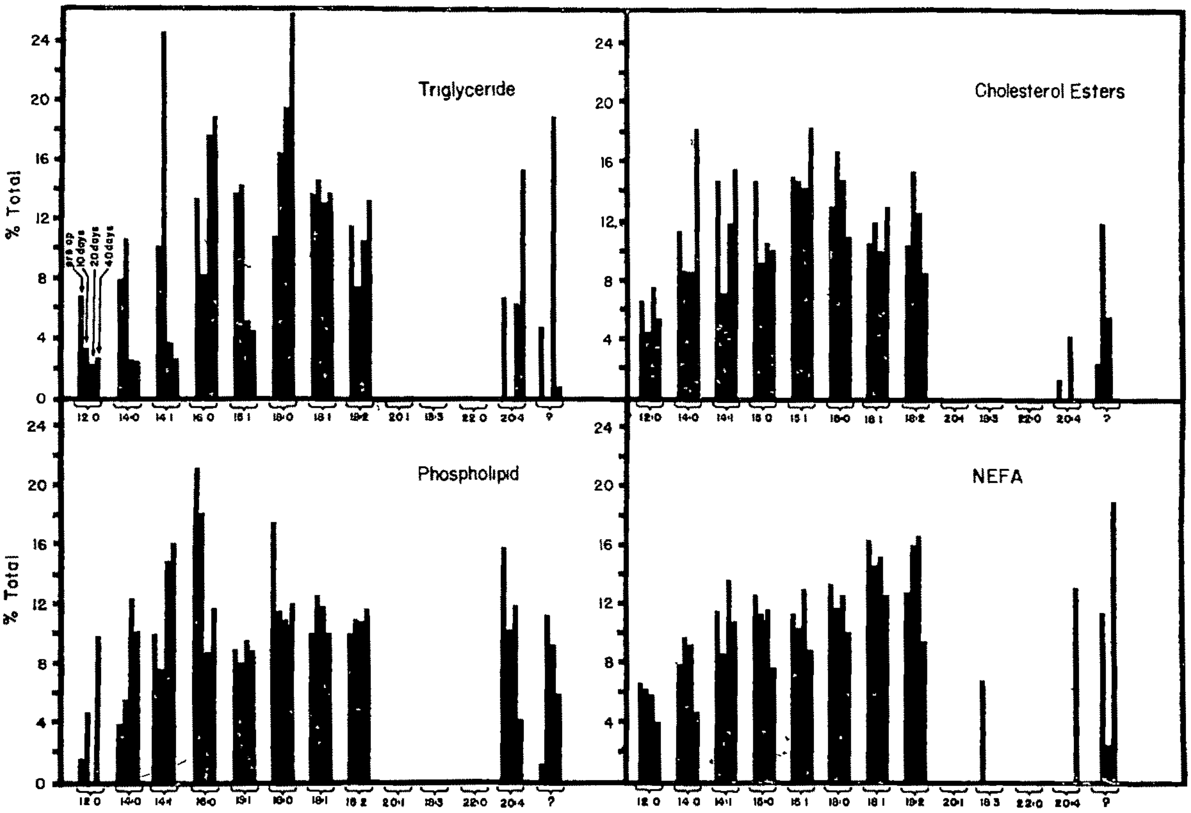

Fig 1 Total percentage of plasma fatty acids (GLC) in a canine hepatic homograft (HHM-12) The bar graph shows the fatty acids, by carbon chain length, for each of the four periods

thin-layer chromatograph (TLC) plate coated with 1 mm of silica gel *G* The solvent used consisted of redistilled Skelly Solve *B* ethyl ether glacial acetic acid (70 30 1 v/v) A standard was applied to each TLC plate to locate the four lipid classes (1) phospholipid, (2) NEFA and cholesterol, (3) triglycerides and (4) cholesterol ester[8] The plates were run, standard developed and sample fractions were immediately scraped into a test tube and extracted from the silica gel with chloroform methanol (3 2 v/v) These four fractions were individually saponified, esterified and metholated by a modification of Metcalfe's[9] methanol-boron-trifluoride fatty acid metholation procedure

The fatty acids were analysed in a Barber Colman Model-20 gas chromatograph (GLC) which was equipped with an argon–tritium ionization detector The column specifications are ethylene glycol succinate (15 per cent) on 'Chromsorb' (100–110 mesh) support, inlet pressure of 30 p s i. argon and column temperature of 185° C Hormel Institute standards were used before and after each day's run The peaks were calculated by the "absolute-peak-area" method (height × width at 1/2 height) using pure fatty acids as qualitative standards The results are expressed as percentage total for each fatty acid Each fatty acid is represented by a pre-operation, 10, 20 and 40 day post-operation value for each dog[2]

Early liver injury was observed in each of the three dogs as determined by standard liver function tests Only one of the animals (HHM-5) developed hyperbilirubinaemia and died after 100 days There was in each animal an increase in alkaline phosphatase serum glutamic oxalacetic transaminase (SGOT) and serum glutamic pyruvic transaminase (SGPT) More detailed data have been presented before[1]

The lipid profile showed that total and esterified cholesterol and phospholipid dropped to about 50 per cent of the pre-operation value in the first 10 days but returned to the pre-operation range in 30–40 days Triglycerides remained in the pre-operation range[10] The NEFA fluctuated but exhibited no obvious trend

The fatty acid data are reported in two ways (1) by a graph showing a representative fatty acid pattern in one animal (HHM-12) for each lipid class (Fig 1), and (2) by a bar graph (Fig 2) showing the unit changes in short chain versus long chain and saturated versus unsaturated fatty acids in each dog as related to the individual animal's own pre-operation value The lipid class is reported during each of the four periods of the study

For convenience in this study, the fatty acids were divided into two groups Fatty acids from C 12 0 lauric to C 16 1 palmitoleic are designated as shorter chain fatty acids Long chain fatty acids are designated C 18 0 stearic to the unidentified peak which is present after C 20 4, arachidonic This unidentified peak (retention time t_R 60 min) appears after C 20 4 (t_R 50 min) but before C 24 0 (t_R 66 min) The peak is not present after hydrogenation, indicating that it is an unsaturated fatty acid

Changes occurring in the individual fatty acids of dog HHM-12 during the four time periods are illustrated in Fig 1 This dog's fatty acid pattern appears to be the median of the three dogs A typical prevalence of long chain fatty acids in the phospholipid fraction is present It is also interesting to note that in the NEFA fraction there is a general quantitative increase as the chain length increases

The data in Fig 2 are an expression of the unit variation between the pre-operation value and each of the three post-operation periods for each animal Each animal acts as its own control There is a noticeable increase in the long chain fatty acids in two of the dogs but not in dog HHM-5 Here the shorter chain fatty acids increase After transplantation the unsaturated fatty acids increase in all classes except HHM-12's triglyceride and HHM-5's phospholipid fraction, as seen in Fig 2 It is interesting to note that there is a fatty acid ratio of 40 per cent

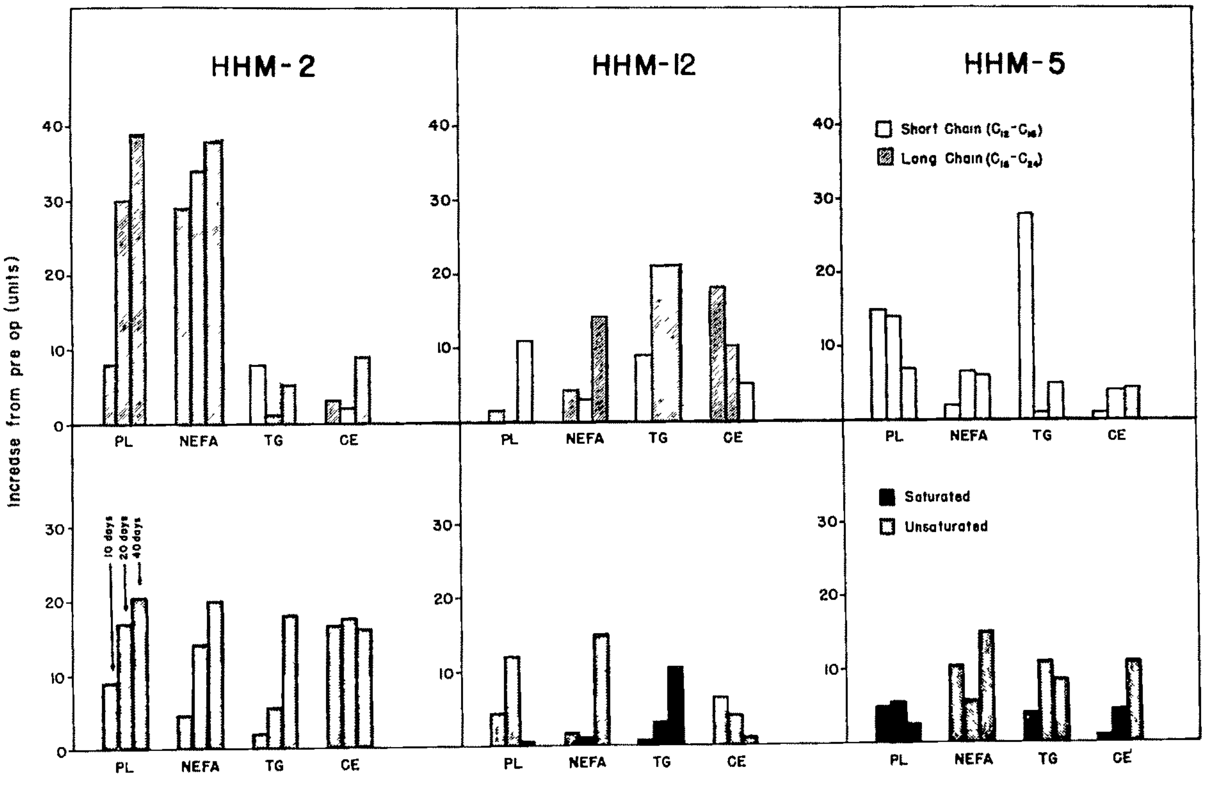

Fig 2 The data on this graph were derived from the difference between plasma fatty acids (GLC) pre-operative and post-operative for each of the three periods Each animal is its own control The results express the unit change after transplantation

saturated to 60 per cent unsaturated which remains constant for all dogs pre and post-operatively

The fatty acids most prevalent in the dog food were oleic, palmitic, linoleic, stearic and linolenic, in that order Neither the unknown peak nor the C 20 4, arachidonic, peaks were present

Dog HHM-2 differs from the other two dogs in that there is a larger percentage (53–67 per cent against 39–47 per cent) of saturated fatty acids in all classes in the pre-operation sample This is because of a high proportion of C 12 0 and C 14 0 in the phospholipid, NEFA and cholesterol ester fractions as well as C 16 0 and C 18 0 in the triglyceride fraction By the fortieth day the saturated fatty acids of dog HHM-2 had dropped to the range (36–51 per cent) of the other two dogs

As may be expected, there is more continuity between fatty acid changes within each dog rather than between the three dogs Two of the dogs (HHM-2, HHM-12) show a general increase in long chain fatty acids, while one dog (HHM-5) exhibits an increase in shorter chain fatty acids There is a general increase in the unsaturated fatty acids for all dogs, the exceptions being in dog HHM-5 phospholipid and cholesterol ester fractions and dog HHM-12 triglyceride fraction

The plasma of two dogs (HHM-2 and HHM-12) and the control dogs contains an increased amount of long chain unsaturated fatty acids This may be a result of a mobilization of the adipose tissue, for long chain fatty acids are found primarily in fat stores Carter[11] states that fatty acids with less than twelve carbon atoms cannot be stored in the animal's body and so must be oxidized as they are absorbed

Another factor which could cause an increase in long chain unsaturated fatty acids is that, theoretically, animal tissue cannot synthesize linoleic acid (C 18 1) The animal therefore depends entirely on an external source of supply, namely the diet The third largest fatty acid content in the dog food was linoleic acid Once present in the cell it undergoes a sequence of desaturation and elongation to form arachidonic acid and other long chain polyunsaturated fatty acids[12]

It is obvious that the enzyme systems of the transplanted liver are affected, for alkaline phosphatase, SGOT and SGPT are altered, as already noted[1,3] Hexadecanoyl dehydrogenase, the enzyme which acts on the acyl Co *A* derivatives of the long chain fatty acids, may therefore also be altered

Dog HHM-5 was the one which exhibited a rise in the shorter chain unsaturates, notably in the phospholipid fraction This dog died of acute pneumonia a little more than 100 days after the operation Further research will be necessary to clarify this interesting observation, for pneumonia is one of the major causes of death in liver transplants

Temporary plasma lipid changes in liver transplant dogs seem to be caused by immunogenic and operative trauma Plasma lipids of control animals (without transplant livers) were not obviously affected by the immunologic therapy but there may be subtle changes in fatty acid metabolism

In the hepatic homograft, mobilization of long chain fatty acids from the adipose tissue may be a natural defence mechanism to supply the liver with "essential fatty acids" for phospholipid synthesis Phospholipids in turn play an important part in the reduction of excess fat in the liver and alveoli function in the lung

Numerical Taxonomy and Influenza *B* Virus

by
ANNA M. LEE

Epidemiology Branch,
National Cancer Institute,
National Institutes of Health,
Bethesda, Maryland

Analysis of the reactions of influenza *B* virus with various antisera has clarified the relationships among virus strains

It may not be easy to see immunological relationships within several virus strains from experimental data, such as those in Table 1, which shows titres from a cross-haemagglutination inhibition (HAI) test involving strains of influenza *B* For clarification, these data have been subjected to numerical taxonomic analysis The methods, which may be valuable in predicting pathogenicity of newly isolated strains and in determining polyvalence of vaccines required, should be useful for summarizing information about a variety of other organisms

The values given in Table 1 were "normalized" by a logarithmic transformation Virus strains were then compared two at a time, the reactions of a virus strain with each of the antisera being considered as multivariate observations on that strain Thus row 1 of Table 1 contains eleven observations on virus V_1, row 2 contains eleven observations on V_2, and so on From each replicate of the experiment there would be eleven additional observations on each strain As a measure of the similarity between V_1 and V_2, the sample product-moment correlation coefficient r was computed for the eleven pairs of (logarithmic) observations For V_1 and V_2, $r = 0\ 82$ Correlations calculated from data in Table 1 (after logarithmic transformation) are given in Table 2 V_{10} and V_{11} are most closely related because their correlation coefficient is 0 98, V_1 and V_4 have a correlation of 0 00 and are not related V_1 and V_6 have the strongest negative relationship ($r = -0\ 59$)

S_1 to S_{11} represent antisera from ferrets immunized with virus strains V_1 to V_{11}, respectively Homologous titres are underlined The value <8 was interpreted as 4

This matrix of correlations was analysed for "clusters" or "families" of virus strains One method used was Sokal and Michener's clustering by average linkage (weighted pair-group method, WPGM)[1], by which admission of a strain into a cluster is based on an average of the correlations of that strain with the existing members of the cluster Results of this analysis are represented by a dendrogram (Fig 1) The abscissa is used only to separate virus strains, whereas the ordinate shows the similarity coefficient (correlation) scale from +1 00 to −0 40 For example, V_5 and V_6 are linked at 0 82 and their average correlation with V_7 is 0 78 When correlation is 0 90 there are two clusters and seven individual strains; and when correlation is 0 75 four clusters of viruses are seen (V_1, V_2), (V_4, V_5, V_6, V_7), (V_8, V_9, V_{10}, V_{11}) and (V_3) An investigator wishing to prepare a vaccine against these strains might determine a reasonable level of correlation and include one strain from each of the clusters seen at that level

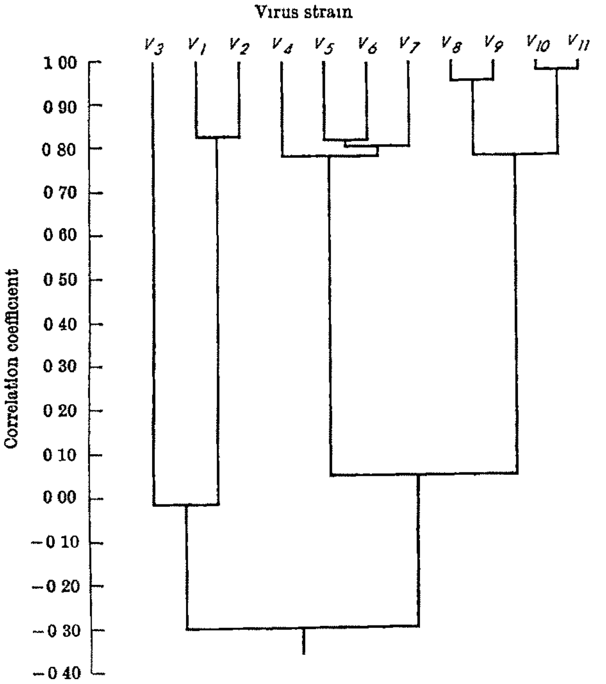

Fig 1 Dendrogram showing relationships between strains of influenza *B* virus from analysis of correlations in Table 2 by Sokal and Michener's clustering by average linkage procedure (WPGM using simple averages)

Table 2 CORRELATIONS BETWEEN VIRUS STRAINS

	V_2	V_3	V_4	V_5	V_6	V_7	V_8	V_9	V_{10}	V_{11}
V_1	0 82	−0 01	−0 00	−0 41	−0 59	−0 37	−0 45	−0 36	−0 18	−0 17
V_2		−0 02	0 04	−0 35	−0 57	−0 22	−0 33	−0 34	−0 31	−0 35
V_3			−0 56	−0 24	−0 37	−0 14	−0 46	−0 36	−0 11	−0 17
V_4				0 75	0 73	0 78	0 23	0 23	−0 23	−0 12
V_5					0 82	0 80	0 04	−0 03	−0 32	−0 28
V_6						0 77	0 54	0 51	0 12	0 19
V_7							0 23	0 25	−0 16	−0 07
V_8								0 96	0 74	0 77
V_9									0 77	0 84
V_{10}										0 98

Principal components analysis[2] provided a second means of identifying clusters of virus strains From data in Table 1 each virus strain was considered as a point in eleven dimensional space the co-ordinates of which correspond to the eleven observations (titres) for the virus Analysis of correlations in Table 2 revealed that most of the variation (87 per cent) in the original data occurs in a three dimensional space, which corresponds to the first three principal components of the correlation matrix Fig 2 depicts the eleven virus strains with respect to these principal component axes Four clusters of virus strains are seen (V_1, V_2), (V_4, V_5, V_6, V_7), (V_8, V_9, V_{10}, V_{11}) and (V_3) These clusters are essentially the same as those appearing in the dendrogram, which is reassuring because principal components analysis is mathematically far more sophisticated than the average-linkage procedure

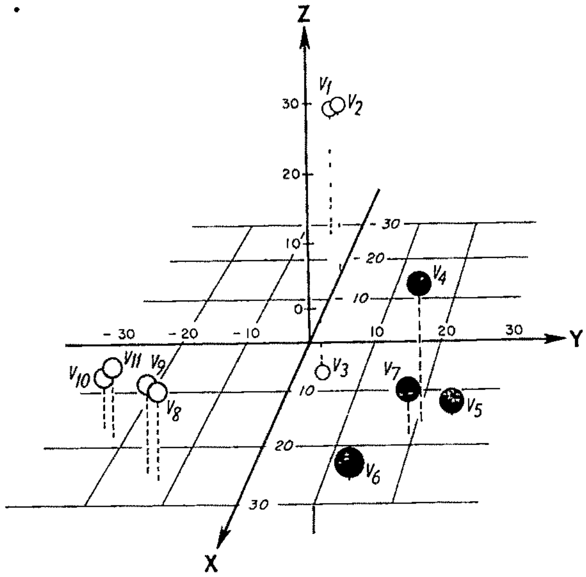

Fig 2 Graph of first (*X*), second (*Y*) and third (*Z*) principal components for eleven strains of influenza *B* virus The *Z* scale has been elevated 0 05 units above the *X*–*Y* plane to simplify presentation of "virus" points the *Z* co-ordinate of which is less than zero

The results indicate that these strains of influenza virus fall into groups according to the date of their isolation This is not a new observation, of course, but the relationships are more clearly visualized by numerical taxonomy

Computer-simulated experiments were conducted to evaluate these two methods of cluster analysis and two further methods (*a*) McQuitty's elementary linkage analysis[3] and (*b*) Sneath's clustering by single linkage[4] Artificial data, resembling real data from HAI experiments involving seven or ten virus strains, were obtained by sampling from twenty-one different multivariate normal populations The computer experiments were planned so that the "virus strains" could be expected to cluster in given patterns, correlations between strains within the same cluster ranged from about 0 60 to 0 95 in normal populations from which samples were drawn The four methods of cluster analysis were compared on the basis of the proportion of samples from each population for which the "virus strains" were "correctly" clustered.

Ease of computation was another basis for comparison of methods, and both two-replicate and unreplicated computer experiments were examined

Several conclusions were drawn from the analysis of computer experiments (*a*) When the correlation coefficient is used to measure similarity between virus strains, classifications based on two-replicate experiments are more reliable, as might be expected, than those based on unreplicated experiments regardless of the method of cluster analysis employed (*b*) Sokal and Michener's average-linkage analysis and principal components analysis are comparably "accurate" in classifying the number of virus strains used in this study (up to ten) when the correlation coefficient is the measure of similarity (The methods of average-linkage analysis and principal components analysis seem to complement each other, although the end results of the two differ somewhat in appearance, while the former method is simpler computationally, one might perform both analyses if possible) (*c*) McQuitty's elementary linkage analysis tends to yield too many clusters and is the least satisfactory of the four procedures investigated

Sneath s clustering method, which bases admission of a virus strain to a cluster on a single linkage of the virus with any individual member of the cluster, is logically less appealing than Sokal and Michener's technique, which admits a virus strain to a cluster on the basis of an average linkage with members of the cluster

Numerical taxonomic methods other than those presented here seem to be useful in the study of influenza Of the many types of cluster analysis, only four of the more widely known were included in the present study Various measures of similarity between virus strains, among them a normalized Euclidean distance function, have been considered instead of the correlation coefficient The mean titre ratio[5], a commonly used measure of serological similarity between two strains of influenza virus, is not recommended for numerical taxonomic studies, because it utilizes little of the available information in making a comparison

Numerical taxonomy affords a means for simplifying visualization not only of the results of serological tests, as presented here, but also of other biological entities on which a number of quantitative measurements have been made

This research was supported by a grant from the US Public Health Service I thank Dr Schork and Dr B Berlin for their advice and Miss E Minuse for supplying data

Biological Phase Relationships

by

MARTIN MACKLIN

Bioengineering Group,
Case Western Reserve University,
Cleveland, Ohio

By treating hydra as a multi-phase system with each cell type constituting a separate biological phase the minimum number of components necessary to control cell differentiation can be determined

BURNETT[1] has suggested that growth and cell differentiation in hydra are regulated by two factors which he called stimulator and inhibitor He further suggested that the relative concentrations of these two factors account for the morphological changes which occur along the body column of the hydra Webster[2] has proposed a slightly different model in which he suggested that the interrelation of two factors—"level of inhibition" and "threshold for inhibition"—controls hypostome formation in hydra Others (for example, ref 3) also suggest that polarity in hydra is controlled by the interrelation of two factors or materials

Recent experiments[4-6], however, have suggested that inorganic ions control differentiation in some situations The authors have suggested that cellular control can be effected by the modification of membrane properties by hormonal substances or growth factors. A change in membrane selectivity caused by growth factors would cause intercellular ionic compositions to change A change in ionic composition is then assumed to cause a change in cell properties, that is, differentiation or growth I do not intend to argue this hypothesis, but rather to indicate a possible method for determining the minimum number of controlling factors for cell differentiation The argument to be presented relates specifically to hydra, but it is applicable to other biological systems as well, and the reference to hydra was selected primarily for convenience

Biological Phases

Biological systems can be characterized as heterogeneous systems composed of separate and distinct elements called cells, spaces and fluids If we take all of the elements of a particular type (say, epithelial cells) they might be said to constitute a single biological phase Each biological phase must be distinct and must be separated from the other phases, but a given phase may itself be broken into parts as long as each portion of a phase is the same as every other portion of that phase This is analogous, for example, to an ice–water system in which ice constitutes a single phase whether it is a single piece of ice or many pieces It will be assumed that the state of a biological system is determined by the phases and the controlling components which determine the phases The controlling components are the constituents of one or more of the phases which are responsible (that is, causal factors) for the presence of the various phases That is, they are the minimum set of constituents the relative concentrations of which determine the relative amount of each phase The constituents, including the special set called components, constitute the entire biological system Each biological phase is recognized as being distinct morphologically because of the presence of distinct constituents For a biological system in steady state the mole fractions of the components in the phases can be assumed to determine completely the state of the system For the co-existence of two biological phases I assume that one independent component is required to describe the state of the system Water is assumed to have a constant concentration throughout the biological system Two solutes, with the mole fraction of one dependent on the mole fraction of the other, are therefore required to establish the relationship between two phases Implicit in this argument is the assumption that by changing the mole fractions of the components the relative amounts of the two phases will correspondingly change just as ice becomes water when the temperature or pressure changes

If three phases co-exist, then the number of independent components required is two, or a system of co-existing biological phases is specified by a minimum of one less independent component than the number of phases Furthermore, it should be noted that the same components could be responsible for the regulation of more than one phase interaction in the same system Before discussing how the phase relations apply to hydra a more precise derivation of the deductions presented here will be given

Derivation of Steady State Phase Relationship

The phase rule was derived by Gibbs[7] to apply to equilibrium systems, and other authors[8-10] in extensive discussions of the derivation or the application of the phase rule consider only equilibrium situations Biological systems, however, are not in thermodynamic equilibrium and therefore, to describe cell differentiation or other biological phase relationships, it is necessary to derive a relationship in which equilibrium is not assumed This is now done

The Gibbs function for constant temperature and pressure is given by

$$dG = \sum_{i=1}^{q} \mu_i dn_i \qquad (1)$$

where G is the Gibbs free energy, μ_i is the chemical potential of the ith component and n_i is the number of moles of the ith component If time derivatives are used, then

$$dG/dt = \sum_{i=1}^{q} \mu_i dn_i/dt \qquad (2)$$

Because G is an additive property, if the system is considered to be composed of r distinct phases with q components then

$$G = \sum_{j=1}^{r} G_j, \text{ and } dG/dt = \sum_{j=1}^{r} \sum_{i=1}^{q} \mu_{ij}\, dn_{ij}/dt \qquad (3)$$

where the double subscript refers to the ith component in the jth phase

A biological system, such as a single hydra polyp, which has a constant shape and a relatively constant composition with time is said to be in steady state That is, any accretion of material is exactly balanced by a corresponding loss of material New cell divisions occur at an approximately uniform rate and are balanced by a loss of cells at the body extremities and food input is balanced by waste product outflow The steady state situation is considered to occur when the average flow of materials, including cell division and cell death, is constant with time Analytically, this is described by saying that the change in the flow or the change in the flux of a material with respect to time is zero, that is, flows are constant At steady state therefore the time derivatives become equal to zero and

$$dG/dt = \sum_{j=1}^{r} dG_j/dt = 0, \text{ or } dn_j/dt = \sum_{j=1}^{i} dn_{ij}/dt = 0 \qquad (4)$$

Thus the flow of the ith component is assumed to be constant throughout the animal and flow between any two phases j and $j+1$ is also constant For constant flow to exist the driving force for the flow or the difference in chemical potential between two phases $(\Delta\mu^{i}_{j\rightarrow j+1})$ for the ith component must be constant There are r phases, and so this gives $r-1$ restricting conditions for each of the q components Or there is a total of $q(r-1)$ internal restricting conditions on the system relating to the distribution of the components which control the biological state

If instead of moles (n) mole percentage composition is used to describe the composition of each phase, then there are $q-1$ independent composition variables required to describe each of the r phases or $r(q-1)$ composition variables for the systems We define the number of degrees of freedom (DF) for the system as the difference between the number of restrictive conditions and the number of composition variables or

$$DF = q(r-1) - r(q-1) = r - q \qquad (5)$$

The degrees of freedom give the number of composition variables that must be arbitrarily selected so that the state of the system may be defined

Phase Relations in Hydra

For hydra the r phases consist of cell types with each cell type being a distinct phase, but all cells of the same type constitute only a single phase The q components are the factors controlling cell differentiation and growth, that is, growth factors, hormones or inorganic ions In hydra there are eleven principal cell types which are contained in two epithelial layers The two layers called the epidermis and gastrodermis are separated by a cell-free mesogloea All the cell types seem to derive from two stem cells, the interstitial or neoblast cell and the epithelial cell The two cell lines have never given evidence of interchanging, that is, a cell in one line differentiating into a cell of the other line The two cell lines seem therefore to be essentially independent, and we are probably dealing with two distinct systems This independence is related to differentiation capabilities and is not meant to suggest that certain positional or gradient effects do not act simultaneously on both cell lines

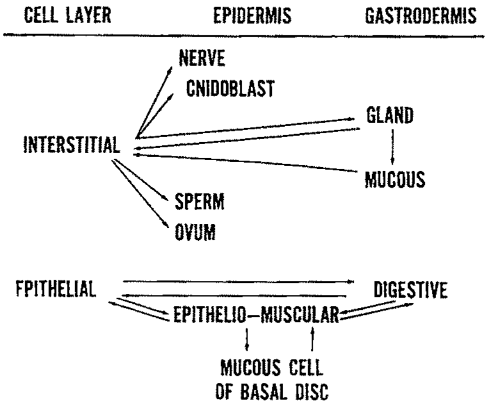

Fig 1 Pathways of cellular differentiation and dedifferentiation in hydra showing location of event by cell layer Cell divisions for both stem cells occur in both cell layers

The stem cells divide and provide a continuing supply of cells which differentiate into all of the other cell types along the pathways shown in Fig 1 The particular cell layer in which each cell type is found is also indicated in Fig 1 We have assumed that there are two distinct cell lines, and so Fig 1 could be redrawn into two figures with triangular co-ordinates (Fig 2), one for each cell line Fig 2 is drawn so that cell types found adjacent in the animal are adjacent in the phase diagram, correspondingly, cell types which do not occur in juxtaposition on the phase diagram also do not usually occur in immediately adjacent areas in the animal Cell division is included as a distinct phase because it can be considered to be a state of differentiation[1] Each cell type (phase) is represented by an area, and cell (or phase) transformations occur across boundaries An intersection of boundaries in Fig 2 represents an invariant association of cell types (phases) Moving away from an intersection along a boundary

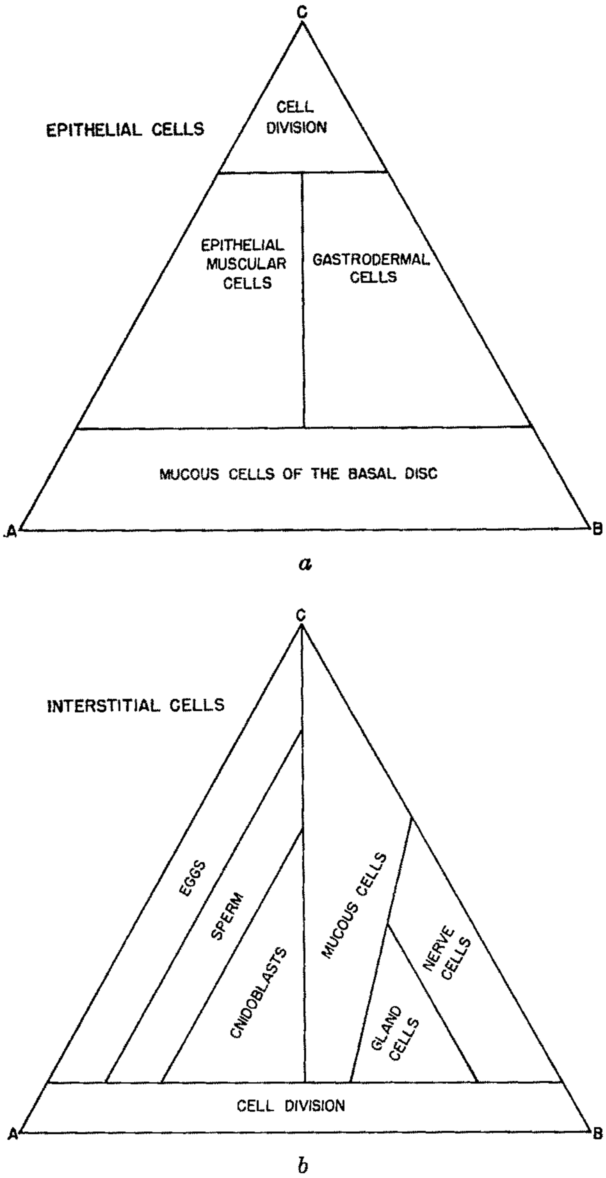

Fig 2 Phase diagrams for epithelial cell and interstitial cell lines An area on the phase diagram represents a single cell type and transformations occur across boundaries The factors *A*, *B*, *C* are shown to indicate how three components may interact to control the phase behaviour (differentiation and division) of the two cell lines The composition at any point on the diagram is found by the intersection of lines drawn perpendicular to the sides of the diagram, the proportion of *B* being read from the side opposite apex *B*, and so on

represents a state with one degree of freedom, that is, one composition variable can be arbitrarily chosen An area represents a state with two degrees of freedom The three variable factors or components, which is the minimal set for zero degrees of freedom, are represented along the three sides of the phase diagram Fig 2 represents the actual situation in hydra, in which three cell types of a given cell line jointly exist only within a very restricted area but two cells from the same cell line co-exist in a much larger area. For each cell line, for DF $=0$, we therefore have $r=3$ for the three co-existing phases at an intersection on the phase diagram; therefore $q=r=3$, or, to explain the observed phase behaviour, at least three components are necessary There is no way of predicting whether or not the same components will be active in controlling both cell lines If the interstitium between cells or the mesogloea is considered as another phase, then a four-dimensional phase diagram would be required and $q=r=4$ at an intersection on the phase diagram Thus three or four components are required to describe the biological phase behaviour in hydra depending on the part played by the interstitium in cell regulation

An alternative way of analysing the phase behaviour of the hydra cells is to ascribe properties to the stimulator (x) and inhibitor (I) substances[1] similar to those usually given in thermodynamics to temperature and pressure Now equation (5) becomes

$$\mathrm{DF} = r-q+2 \tag{6}$$

where 2 includes the variables x and I, and q includes the composition variables This system cannot be easily represented graphically, but we can imagine the x and I substances exerting a thermodynamic stress on a cell, thereby causing a change in $\Delta\mu_i$ between two phases The change in chemical potential causes $dn_i/dt \neq 0$ until a steady state is re-established This effect can be likened to the effect of temperature and pressure on phases under Le Chatlier's principle The two factor system of Burnett or Webster is therefore clearly inadequate to explain the phase behaviour of hydra cells We are therefore fully justified in searching for a three or four component system (which may be mediated by two growth factors) which exerts control over cell differentiation and division in hydra

Evolutionary Rate at the Molecular Level

by
MOTOO KIMURA

National Institute of Genetics,
Mishima, Japan

Calculating the rate of evolution in terms of nucleotide substitutions seems to give a value so high that many of the mutations involved must be neutral ones

Comparative studies of haemoglobin molecules among different groups of animals suggest that, during the evolutionary history of mammals, amino-acid substitution has taken place roughly at the rate of one amino-acid change in 10^7 yr for a chain consisting of some 140 amino-acids For example, by comparing the α and β chains of man with those of horse, pig, cattle and rabbit, the figure of one amino-acid change in 7×10^6 yr was obtained[1].

This is roughly equivalent to the rate of one amino-acid substitution in 10^7 yr for a chain consisting of 100 amino-acids.

A comparable value has been derived from the study of the haemoglobin of primates[2]. The rate of amino-acid substitution calculated by comparing mammalian and avian cytochrome *c* (consisting of about 100 amino-acids) turned out to be one replacement in 45×10^6 yr (ref. 3). Also by comparing the amino-acid composition of human triosephosphate dehydrogenase with that of rabbit and cattle[4], a figure of at least one amino-acid substitution for every $2{\cdot}7 \times 10^6$ yr can be obtained for the chain consisting of about 1,110 amino-acids. This figure is roughly equivalent to the rate of one amino-acid substitution in 30×10^6 yr for a chain consisting of 100 amino-acids. Averaging those figures for haemoglobin, cytochrome *c* and triosephosphate dehydrogenase gives an evolutionary rate of approximately one substitution in 28×10^6 yr for a polypeptide chain consisting of 100 amino-acids.

I intend to show that this evolutionary rate, although appearing to be very low for each polypeptide chain of a size of cytochrome *c*, actually amounts to a very high rate for the entire genome.

First, the DNA content in each nucleus is roughly the same among different species of mammals such as man, cattle and rat (see, for example, ref. 5). Furthermore, we note that the G–C content of DNA is fairly uniform among mammals, lying roughly within the range of 40–44 per cent[6]. These two facts suggest that nucleotide substitution played a principal part in mammalian evolution.

In the following calculation, I shall assume that the haploid chromosome complement comprises about 4×10^9 nucleotide pairs, which is the number estimated by Muller[7] from the DNA content of human sperm. Each amino-acid is coded by a nucleotide triplet (codon), and so a polypeptide chain of 100 amino-acids corresponds to 300 nucleotide pairs in a genome. Also, amino-acid replacement is the result of nucleotide replacement within a codon. Because roughly 20 per cent of nucleotide replacement caused by mutation is estimated to be synonymous[8], that is, it codes for the same amino-acid, one amino-acid replacement may correspond to about 1·2 base pair replacements in the genome. The average time taken for one base pair replacement within a genome is therefore

$$28 \times 10^6 \text{ yr} \div \left(\frac{4 \times 10^9}{300}\right) \div 1{\cdot}2 \doteqdot 1{\cdot}8 \text{ yr}$$

This means that in the evolutionary history of mammals, nucleotide substitution has been so fast that, on average, one nucleotide pair has been substituted in the population roughly every 2 yr.

This figure is in sharp contrast to Haldane's well known estimate[9] that, in horotelic evolution (standard rate evolution), a new allele may be substituted in a population roughly every 300 generations. He arrived at this figure by assuming that the cost of natural selection per generation (the substitutional load in my terminology[10]) is roughly 0·1, while the total cost for one allelic substitution is about 30. Actually, the calculation of the cost based on Haldane's formula shows that if new alleles produced by nucleotide replacement are substituted in a population at the rate of one substitution every 2 yr, then the substitutional load becomes so large that no mammalian species could tolerate it.

Thus the very high rate of nucleotide substitution which I have calculated can only be reconciled with the limit set by the substitutional load by assuming that most mutations produced by nucleotide replacement are almost neutral in natural selection. It can be shown that in a population of effective size N_e, if the selective advantage of the new allele over the pre-existing alleles is s, then, assuming no dominance, the total load for one gene substitution is

$$L(p) = 2\left\{\frac{1}{u(p)} - 1\right\} \int_0^{4Sp} \frac{e^y - 1}{y}\,\mathrm{d}y - 2e^{-4S}\int_{4Sp}^{4S} \frac{e^y}{y}\,\mathrm{d}y + 2\log_e\left(\frac{1}{p}\right) \qquad (1)$$

where $S = N_e s$ and p is the frequency of the new allele at the start. The derivation of the foregoing formula will be published elsewhere. In the expression given here $u(p)$ is the probability of fixation given by[11]

$$u(p) = (1 - e^{-4Sp})/(1 - e^{-4S}) \qquad (2)$$

Now, in the special case of $|2N_e s| \ll 1$, formulae (1) and (2) reduce to

$$L(p) = 4N_e s \log_e(1/p) \qquad (1')$$

$$u(p) = p + 2N_e sp(1-p) \qquad (2')$$

Formula (1′) shows that for a nearly neutral mutation the substitutional load can be very low and there will be no limit to the rate of gene substitution in evolution. Furthermore, for such a mutant gene, the probability of fixation (that is, the probability by which it will be established in the population) is roughly equal to its initial frequency as shown by equation (2′). This means that new alleles may be produced at the same rate per individual as they are substituted in the population in evolution.

This brings the rather surprising conclusion that in mammals neutral (or nearly neutral) mutations are occurring at the rate of roughly 0·5 per yr per gamete. Thus, if we take the average length of one generation in the history of mammalian evolution as 4 yr, the mutation rate per generation for neutral mutations amounts to roughly two per gamete and four per zygote (5×10^{-10} per nucleotide site per generation).

Such a high rate of neutral mutations is perhaps not surprising, for Mukai[12] has demonstrated that in *Drosophila* the total mutation rate for "viability polygenes" which on the average depress the fitness by about 2 per cent reaches at least some 35 per cent per gamete. This is a much higher rate than previously considered. The fact that neutral or nearly neutral mutations are occurring at a rather high rate is compatible with the high frequency of heterozygous loci that has been observed recently by studying protein polymorphism in human and *Drosophila* populations[13–15].

Lewontin and Hubby[15] estimated that in natural populations of *Drosophila pseudoobscura* an average of about 12 per cent of loci in each individual is heterozygous. The corresponding heterozygosity with respect to nucleotide sequence should be much higher. The chemical structure of enzymes used in this study does not seem to be known at present, but in the typical case of esterase-5 the molecular weight was estimated to be about 10^5 by Narise and Hubby[16]. In higher organisms, enzymes with molecular weight of this magnitude seem to be common and usually they are "multimers"[17]. So, if we assume that each of those enzymes comprises on the average some 1,000 amino-acids (corresponding to molecular weight of some 120,000), the mutation rate for the corresponding genetic site (consisting of about 3,000 nucleotide pairs) is

$$u = 3 \times 10^3 \times 5 \times 10^{-10} = 1{\cdot}5 \times 10^{-6}$$

per generation. The entire genome could produce more than a million of such enzymes.

In applying this value of u to *Drosophila* it must be noted that the mutation rate per nucleotide pair per generation can differ in man and *Drosophila*. There is some evidence that with respect to the definitely deleterious effects of gene mutation, the rate of mutation per nucleotide pair per generation is roughly ten times as high in *Drosophila* as in man[18,19]. This means that the corresponding mutation rate for *Drosophila* should be $u = 1{\cdot}5 \times 10^{-5}$ rather than $u = 1{\cdot}5 \times 10^{-6}$. Another consideration allows us to suppose that $u = 1{\cdot}5 \times 10^{-5}$ is probably appropriate for the neutral mutation rate of a cistron in *Drosophila*. If we assume that the frequency of occurrence of neutral mutations is about one per genome per generation (that is, they are roughly two to three times more frequent than the mutation of the viability polygenes), the mutation rate per nucleotide pair per generation is $1/(2 \times 10^8)$, because the DNA content per genome in *Drosophila* is about one-twentieth of that of man[20]. For a cistron consisting of 3,000 nucleotide pairs, this amounts to $u = 1{\cdot}5 \times 10^{-5}$.

Kimura and Crow[21] have shown that for neutral mutations the probability that an individual is homozygous is $1/(4N_e u + 1)$, where N_e is the effective population number, so that the probability that an individual is heterozygous is $H_e = 4N_e u/(4N_e u + 1)$. In order to attain at least $H_e = 0{\cdot}12$, it is necessary that at least $N_e = 2{,}300$. For a higher heterozygosity such as $H = 0{\cdot}35$, N_e has to be about 9,000. This might be a little too large for the effective number in *Drosophila*, but with migration between subgroups, heterozygosity of 35 per cent may be attained even if N_e is much smaller for each subgroup.

We return to the problem of total mutation rate. From a consideration of the average energy of hydrogen bonds and also from the information on mutation of *rIIA* gene in phage T_4, Watson[22] obtained $10^{-8} \sim 10^{-9}$ as the average probability of error in the insertion of a new nucleotide during DNA replication. Because in man the number of cell divisions along the germ line from the fertilized egg to a gamete is roughly 50, the rate of mutation resulting from base replacement according to these figures may be $50 \times 10^{-8} \sim 50 \times 10^{-9}$ per nucleotide pair per generation. Thus, with 4×10^9 nucleotide pairs, the total number of mutations resulting from base replacement may amount to $200 \sim 2{,}000$. This is 100–1,000 times larger than the estimate of 2 per generation and suggests that the mutation rate per nucleotide pair is reduced during evolution by natural selection[18,19].

Finally, if my chief conclusion is correct, and if the neutral or nearly neutral mutation is being produced in each generation at a much higher rate than has been considered before, then we must recognize the great importance of random genetic drift due to finite population number[23] in forming the genetic structure of biological populations. The significance of random genetic drift has been deprecated during the past decade. This attitude has been influenced by the opinion that almost no mutations are neutral, and also that the number of individuals forming a species is usually so large that random sampling of gametes should be negligible in determining the course of evolution, except possibly through the "founder principle"[24]. To emphasize the founder principle but deny the importance of random genetic drift due to finite population number is, in my opinion, rather similar to assuming a great flood to explain the formation of deep valleys but rejecting a gradual but long lasting process of erosion by water as insufficient to produce such a result.

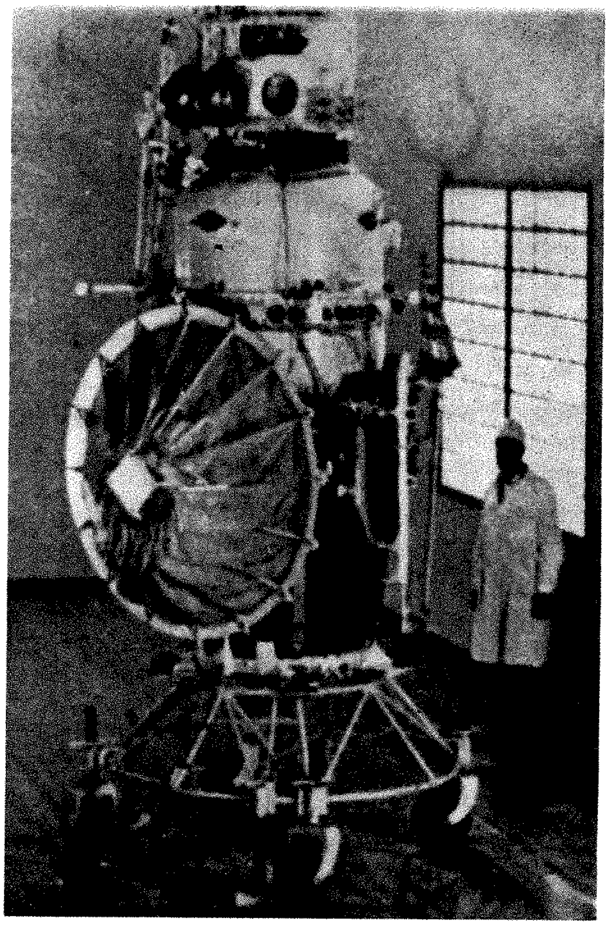
The USSR Venera-4 Probe photographed during Preparation for Flight (TASS)

(see opposite)



The Venera-4 probe, weighing nearly 2,500 lb., was launched from the USSR on June 12, 1967. After 128 days in flight, it was parachuted from the space rocket to make a soft landing on the surface of Venus. Information sent back to Earth from the probe was picked up by the radio telescope at Jodrell Bank and was passed to the Russians for decoding. Some of the results are discussed opposite.

LETTERS TO THE EDITOR

PLANETARY SCIENCE

Superadiabatic Atmospheric Layer on Venus, as inferred from the Venera-4 Probe Measurements

THE USSR Venera-4 probe entered the atmosphere of Venus on October 18, 1967, made the first direct measurements of the physico-chemical characteristics of the lower atmosphere and landed smoothly on the planet's surface[1,2]. The probe's whole descent took place on the night side of the planet, close to the equator and about 1,500 km from the terminator. The probe contained two resistance thermometers, an anaeroid barometer transducer, a densitometer and eleven core gas analysers. Immediately after the probe's parachutes opened at an altitude of 26 km, an atmospheric sample was inserted in five cores. The remaining six cores received samples at an altitude of 23 km. All the analysers operated. The carbon dioxide content turned out to be 90 per cent, with less than 10 per cent error. The water or moisture content turned out to be greater than 0·1 per cent and less than 0·7 per cent. In one analyser the oxygen content was greater than 0·4 per cent. In another analyser the oxygen and water content were less than 1·5 per cent, that is, the oxygen content is somewhere between 0·4–1·4 per cent. Finally, the nitrogen content is less than 7 per cent, for an analyser with this response showed no presence of nitrogen. Table 1, derived from these measurements, presents five atmospheres of differing composition for Venus, depending on the relative amounts of carbon dioxide, between the possible limits 80–99·5 per cent. Probably small quantities of argon and other inert gases are present in the atmosphere of Venus as may be deduced from the composition.

Table 2 presents the temperature and pressure for altitudes from 0 to 25 km. The temperatures are mean values determined from the measurements of the two thermometers; the deviation from the mean in the readings of the two instruments was about ± 7°. From 26 km to the surface, the temperature varied from 313° K to 543° K. The behaviour of temperature with altitude turned out to be almost linear, with a mean temperature gradient of 8·9° km^{-1}. The pressure at the same altitudes varied from 0·7 to 20 atmospheres. The average behaviour of pressure with altitude is shown in Table 2; also, possible errors in its measurement are indicated by minimum and maximum values.

From the data presented in Tables 1 and 2 it is possible to estimate the degree of convective activity in the lower atmosphere of Venus. If the actual temperature lapse rate is represented by γ and the dry-adiabatic rate by γ_d, then there are three possible atmospheric stability conditions

$$\begin{aligned} &\gamma < \gamma_d \text{ stable} \\ &\gamma = \gamma_d \text{ neutral} \\ &\gamma > \gamma_d \text{ unstable} \end{aligned} \tag{1}$$

The necessary condition for the support of vertical motions, up or down, in dry air is a lapse rate greater than the adiabatic rate or a superadiabatic lapse rate ($\gamma > \gamma_d$). The dry adiabatic process operates up to the saturation point of the water vapour. If the greatest possible moisture content of 0·7 per cent obtained by direct measurement of Venera-4 at 23 km is taken, then the condensation level turns out to be about 29 km. If the minimum amount of water vapour (0·1 per cent) is assumed, then the cloud level is about 32 km.

For any gaseous atmosphere,

$$\gamma_d = -\partial T/\partial h = g/C_P \tag{2}$$

where T is the temperature, h the altitude, g the acceleration of gravity and C_P the specific heat at constant pressure of the gas composing the atmosphere. The variation of g with h above any planet can be expressed by

$$g = g_0 R^2/(R+h)^2 \tag{3}$$

where g_0 is the acceleration of gravity at the planet's surface and R is the planet's radius. For Venus[3], $g_0 = 877 \pm 5{\cdot}0$ cm s^{-2} and $R = 6{,}085 \pm 20$ km. The variation of g with altitude is slight in the lower atmosphere of Venus (Table 3). From 1–20 atm, the variation of C_P with pressure is slight for carbon dioxide, molecular nitrogen and argon[4]. The main variation of C_P in equation (2) is therefore caused by its direct variation with temperature. The temperature decreases with altitude (Table 2), and so C_P also decreases with altitude.

Using values of C_P for individual gases accurate to three decimal places[4], calculations were made of the specific heats of the following four mixtures of gases at the temperatures and pressures listed in Table 2: (*a*) 80 per cent carbon dioxide, 7 per cent nitrogen, 13 per cent argon; (*b*) 85 per cent carbon dioxide, 7 per cent nitrogen, 8 per cent argon; (*c*) 90 per cent carbon dioxide, 7 per cent nitrogen, 3 per cent argon; (*d*) 95 per cent carbon dioxide, 5 per cent nitrogen. Calculations were made also for 100 per cent carbon dioxide. These five cases correspond closely to the five Venus atmospheres presented in Table 2. It should be noted that C_P for carbon dioxide and nitrogen are approximately the same for the assumed conditions. The slight amount of water vapour and molecular oxygen was neglected in the calculations.

The value of the specific heat at constant pressure for a gas mixture, consisting of n different gases, C_P, is[5]

$$\bar{C}_P = \frac{1}{\bar{M}} \sum_i^n C_i M_i C_{P_i} \tag{4}$$

where $\bar{M}$ is the average molecular weight of the gas mixture ($\sum_i^n C_i M_i$); C_i is the proportion of constituent gas i; M_i is the molecular weight of constituent gas i and C_{P_i} is the specific heat at constant pressure for constituent gas i.

Table 1. RELATIVE CONCENTRATION (PER CENT) OF CONSTITUENTS IN LOWER ATMOSPHERE OF VENUS (0–26 KM) FOR VARIOUS PERCENTAGES OF CARBON DIOXIDE[2]

Constituent	Carbon dioxide (per cent) 80	85	90	95	99·5
Water vapour	0·1–0·7	0·1–0·7	0·1–0·7	0·1–0·7	0·1
Molecular oxygen	0·4–1·4	0·4–1·4	0·4–1·4	0·4–1·4	0·4
Molecular nitrogen	0·0–7·0	0·0–7·0	0·0–7·0	0·0–4·5	0
Other inert gases, such as argon	10·9–19·5	5·9–14·5	0·9–9·5	0·0–4·5	0

Table 2. TEMPERATURE AND PRESSURE VERSUS ALTITUDE IN THE VENUS LOWER ATMOSPHERE[1,2]

Altitude (km)	Temperature (° K)	Pressure (atm) Minimum	Average	Maximum

Next, using the specific heats calculated from (4) and g from (3), adiabatic lapse rates were computed from (2). The results are given in Table 3, which shows the adiabatic lapse rate in degrees per kilometre in the lower atmosphere of Venus from 0 to 25 km for the five different possible compositions (Table 1).

The actual lapse rate of 8·9° km^{-1} is greater than the adiabatic lapse rates for mixtures in Table 3 containing 90 per cent or greater amounts of carbon dioxide at altitudes up to 10 km. For the 85 per cent carbon dioxide mixture the altitude of the superadiabatic layer is about 5 km, while for the 80 per cent carbon dioxide mixture it is at the surface (0 km). No appreciable changes are made in the values in Table 3 if they are calculated using either the minimum or maximum pressures displayed in Table 2. Likewise, no significant changes result if the calculations are made using temperatures either 10° less or 10° greater at all altitudes.

These detailed calculations therefore indicate that if the lower atmosphere of Venus consists of 85 per cent or more carbon dioxide, as seems probable, then it contains a fairly thick (5–10 km) superadiabatic atmospheric layer at its surface. According to the criterion in (1), the lower atmosphere is unstable and favours large scale vertical motions. These conclusions, based on measurements made on the night side of Venus, should hold even more strongly for the day side. The presence of such a marked convective layer and its influence on dust particles can have profound effects on the dynamics of the lower atmosphere of Venus[6].

Monsoon over the Indus Valley during the Harappan Period

THERE is adequate archaeological evidence[1] that the Harappans, who flourished in the Indus Valley between 2500 and 1700 ± 100 BC, lived in very much moister

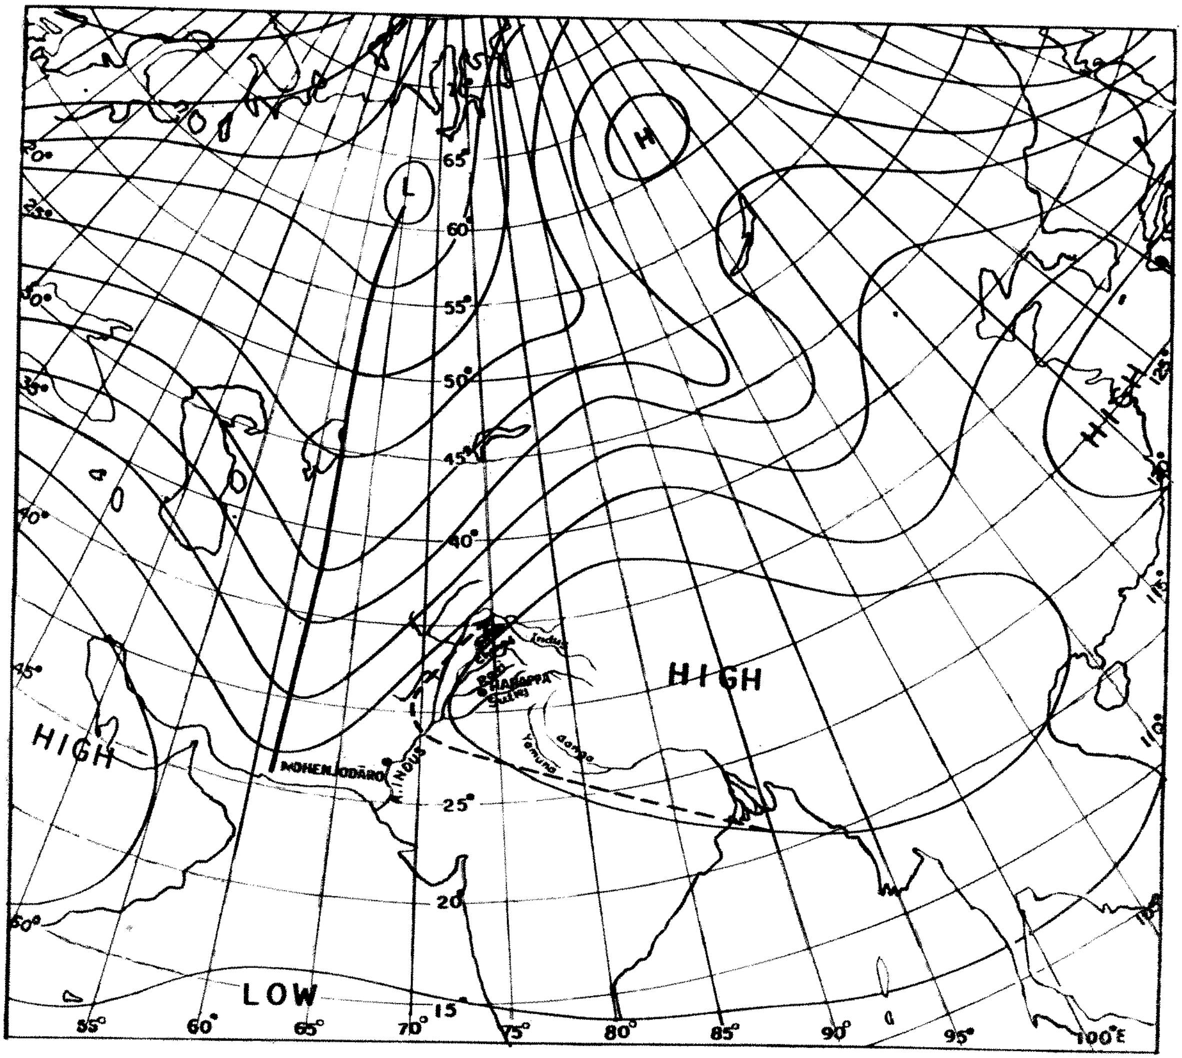

Fig. 1. Schematic 300 mbar flow patterns (approximately 9·0 km above sea level) on a day when a middle-latitude quasi-stationary trough causes a change in the track of a monsoon depression from west-north-west to north or north-east. Note the positions of the famous cities of Mohenjodāro and Harappa and the catchments of the Indus and its tributaries in relation to the middle latitude trough and the track of the monsoon depression before and after it curves to the north. ———, Contours at 300 mbar level; - - - -, track of monsoon depression at sea level.

climatic conditions than those which exist today. Archaeologists[2,3] have also emphasized the occurrence of intermittent floods in the Indus valley during the Harappan period. These conclusions, which are based on archaeological evidence, are also supported by the following meteorological considerations.

The patterns of 1,000–500 mbar thicknesses recently published by Lamb, Lewis and Woodroffe[4] clearly indicate that in 2000 and 500 BC, there was a mean trough in the upper westerlies with its axis along 70° E. and extending from high latitudes to 45° N. in the month of July. These thickness charts do not indicate the existence of such a mean trough anywhere between 0° E. and 160° E. in modern times.

I have made a detailed study of the daily northern hemisphere charts for 1962–66, with good coverage of data to the north of the Indo–Pakistan sub-continent, and have found that quasi-stationary troughs in the westerlies at the 500, 300 and 200 mbar levels occasionally extend into north-west Pakistan and induce monsoon activity ahead of such troughs[5]. They are deep enough to alter the configuration[6] of the sub-tropical high to their east and are thus indirectly responsible for causing any monsoon depressions moving in a west-north-westerly direction towards longitude 78° E., to curve to the north or north-east towards the Punjab (Pakistan), Punjab (India) and Kashmir (Fig. 1). Before the depression curves to the north, the area of heavy rainfall lies in the left front quadrant[7] of the depression. After the depression has curved to the north, however, this area of heavy rainfall shifts to the northern sector of the depression, with the active monsoon area chiefly determined by the area of high level divergence ahead of the trough in the upper westerlies[5,8]. In the later stages of its north-eastward movement, the monsoon depression causes floods in the upper reaches of the Himalayan rivers to the west of 78° E. An example of this can be seen in the monsoon depression of September 2–9, 1966. Such depressions curving to the north or north-east were, however, only very occasional during 1891–1960 (ref. 9).

It follows that during the south-west monsoon seasons around 2000–500 BC deep troughs in the upper westerlies must have extended into west Pakistan far more frequently than they do now, inducing monsoon activity and also causing any monsoon depressions from the Bay of Bengal moving towards longitude 78° E., to curve to the north or north-east. These developments would have caused frequent active monsoon conditions over the entire Indus Valley, which is basically a fertile region[10]. Thick vegetation and marsh jungles inhabited by fauna as described by archaeologists[1], and intermittent floods in the Indus and its tributaries, would therefore have characterized the period of the Harappan civilization.

These conclusions are further supported by the recent discovery of considerable reserves of ground water[11] in the arid region of extreme west Rajasthan close to the Indus Valley. Carbon-14 tests carried out[12] by staff of the Tata Institute of Fundamental Research in Bombay, at a place called Palana, 14 miles south of Bikaner (28° 00′ N., 73° 18′ E.) indicate that the ground water there is about 5,000 yr old, this being the upper limit of the true age of the water.

Ultra-low Levels of Terrestrial Ionization

Neher has suggested[1] that the approximate lower limit of the exposure rate resulting from soil radioactivity be taken as 1·4 μr./h, an unpublished value measured by Millikan in Manitoba. Subsequent surveys in Europe and the United States[2,3] reported minimum values for the intensity of terrestrial ionization which averaged approximately 4·5 μr./h. Millikan's value was also less than that found in the exhaustive study by Hultqvist[4], in which the lowest indoor gamma level, as measured in wooden houses, was about 5·5 μr./h.

In 1962, however, during another survey organized by the Health and Safety Laboratory of the US Atomic Energy Commission, Beck *et al.*[5] measured 1·6 μr./h at Copperopolis, California. At a nearby asbestos mine (Pacific Asbestos, Inc.) a value of 0·5 μr./h was measured. The credit for pointing out the diminished radioactivity in this region must go to Wollenberg and Smith[6], who during a search for low-activity materials for counting room enclosures "discovered" not only the Copperopolis site but also an underground facility, the abandoned Red Mountain magnesite mine in the Diablo Mountains in Santa Clara County, California.

In the late summer of 1965 we visited the Red Mountain mine with a thin-walled (0·5 g/cm^2 'Plexiglas') air-filled ionization chamber. This type of chamber has been described elsewhere[7]. After subtracting the cosmic ray contribution, estimated at 0·01 μr./h, the magnitude of the ionization measured in this mine was 0·05 μr./h, with approximately a 100 per cent error (Table 1). Even 0·1 μr./h is a remarkably low value for terrestrial ionization. In New York City, for example, the average background is at least two orders of magnitude larger. Oddly enough, radon was detected during these measurements, and there is the possibility that it originated outside the mine[8], in which case the ionization levels associated with this mine may be even lower.

We also conducted ionization measurements at the Pacific Asbestos open-strip mine at Copperopolis and obtained a value of 3·94 μr./h. This is the same (to within the ±0·09 μr./h error) as the value reported by Shamos and Liboff[7] for the cosmic ray ionization at this pressure (734·7 torr), again implying quite small terrestrial levels.

Table 1. SELECTED IONIZATION INTENSITIES OVER SOIL, NOT INCLUDING COSMIC RADIATION

Location	Exposure rate (μr./h)	Reference
Manitoba	≧1·4	1
Red Mountain mine, Santa Clara County, California	∼0·05	
Pacific Asbestos mine, Copperopolis, California	≲0·09	
Ruberoid mine, Eden Mills, Vermont	1·04 ± 0·21	
Jeffrey mine, Asbestos, Quebec	≲0·09	
Jeffrey mine (after heavy rain)	0·57 ± 0·14	
King Beaver mine, Thetford, Quebec	0·10 ± 0·17	
Salt mine, Houston	∼0·2	*
Denver, Colorado	12·4 ± 1·7	5
Pelham, New York	6·8 ± 0·4	6
Courtright Reservoir, California	20·7 ± 1·4	8
Guarapari, Brazil (monazite sand beaches)	≲2,000	9

All sites are above ground except for the Red Mountain mine, which is 400 ft. below the surface.

* Personal communication from W. Lowder, describing measurements made by H. Beck and W. J. Condon in 1965.

Three other asbestos strip mines have been studied, the Ruberoid mine in Hyde Park, Vermont, the Johns Manville (Jeffrey) mine in Asbestos, Quebec, and the (King Beaver) mine in Thetford, Quebec. These sites, too, exhibited far less than "normal" exposure rates. A summary of the findings is given in Table 1. The comparatively higher reading at the Ruberoid mine may reflect the fact that data were obtained for only 1 day at this location, and this in rainy conditions. Furthermore, the practice at this mine is to rebuild the excavated areas with processed rock and soil, with the inherent possibility of including foreign materials. Compare the two readings for the Jeffrey mine. The second set was taken after an extended rainy period.

As well as these sites, underground salt mines apparently also exhibit rather low levels of radiation. For example, in a mine near Houston, an approximate level of 0·2 μr./h has been determined. It is interesting that the contribution of potassium-40 was negligible, and that there was a substantial concentration of bismuth-214.

To scale the set of values in Table 1 properly, we have included some others. The first, an average of readings taken at an Atomic Energy Commission site in Pelham, New York, is a representative sample of the magnitude encountered over soil. The next value listed, on the other hand, is rather high. It was obtained over a granite outcrop at Courtright Reservoir in the Sierras. (This site serves as a standard for the University of California LRL Health Physics group.) In addition there are, of course, "hotter" regions, the best example of which is the monazite sands area on the Brazilian East Coast, where levels up to 2,000 μr./h are observed[9].

The ultra-low levels listed in Table 1 are almost certainly associated with ultramafic rocks. This is entirely reasonable considering that the concentrations of the principal radioactive contaminants, uranium, thorium and potassium, vary, in the words of Wollenberg and Smith[8], "with the acidity of igneous rocks, being practically nil in the ultramafic rocks". Davis and Hess[10] showed that as the mafic nature of igneous rocks varied between felsic and ultramafic, the concentration of uranium changed from $3·0 \times 10^{-6}$ to $0·03 \times 10^{-6}$ g/g of rock. Included in their samples, coincidently, were specimen rocks from Belvidere Mountain in Vermont, the site of the Ruberoid mine already mentioned. In addition to reporting that gravimetric determinations show "generally between 0·00 and 0·03% for the alkalis in ultramafic rocks", Hamilton and Mountjoy[11] also list the results of an extensive series of flame spectrophotometric analyses on alpine ultramafic rocks, in which the median concentration of potassium oxide was 0·003 per cent. Dunite and serpentine were said to be virtually free of potassium[12]. It is interesting that a constant ratio of potassium to uranium is said to occur[13] in ultramafic rock. In addition, the fact that relatively large regions, either on the Earth's surface or close to it, show ultra-low radioactivity may have significance in connexion with (*a*) the hypothesis[14,15] that the mantle immediately below the Mohorovičić discontinuity consists chiefly of ultra basic (peridotitic) rock, and (*b*) the fact that there are probably "quite severe restrictions . . . on the absolute concentrations of radioactive elements existing in the earth's upper mantle"[16].

Apart from geochemical considerations, perhaps the most interesting aspect is the possible exploitation of such areas for research which requires extremely low backgrounds. Consider, for example, what information can be derived from Fig. 1, which shows the ionization level in Red Mountain mine recorded for 10 min. Full scale is approximately equivalent to 4·0 μr./h. The electrometer zero is shown at the end of the record. Zero drift was measured during this period and found to be negligible.

The large spikes represent bursts of ionization from alpha particles emitted by contaminants in the chamber walls. Some are shown in greater detail in Fig. 2, in a portion of record taken at a higher speed. For those times long after an alpha emission and before another, the mean signal level approaches a net deflexion of about 3/4 of a small division. The cosmic ray level at the mine elevation (3,040 ft.) is 4·3 μr./h, but is greatly attenuated by the 400 ft. of vertical thickness of rock above the ionization chamber. Assuming a specific gravity of 2·5, this corresponds to a depth of $3·1 \times 10^{5}$ g/cm^{2}, enough to reduce the cosmic ray contribution to the order of 0·01 μr./h, and the net magnitude to the previously stated 0·05 μr./h.

By direct counting of pulses for 30 min it was established that there were 0·036 ± 0·003 alphas/sec. This, divided by the interior surface area of the chamber, is equivalent to $1·2 \times 10^{-5}$ alphas/cm^{2}/sec. Sharpe[17] has reported that aquadag coatings (which constituted the interior electrodes in our chamber) emit about $1·9 \times 10^{-5}$ alphas/cm^{2}/s. It is seen, therefore, that the residual contaminantion of the chamber itself is determined in a straightforward way. More elaborate schemes have been used in the past, notably the extrapolation techniques of Hess and Vancour[18].

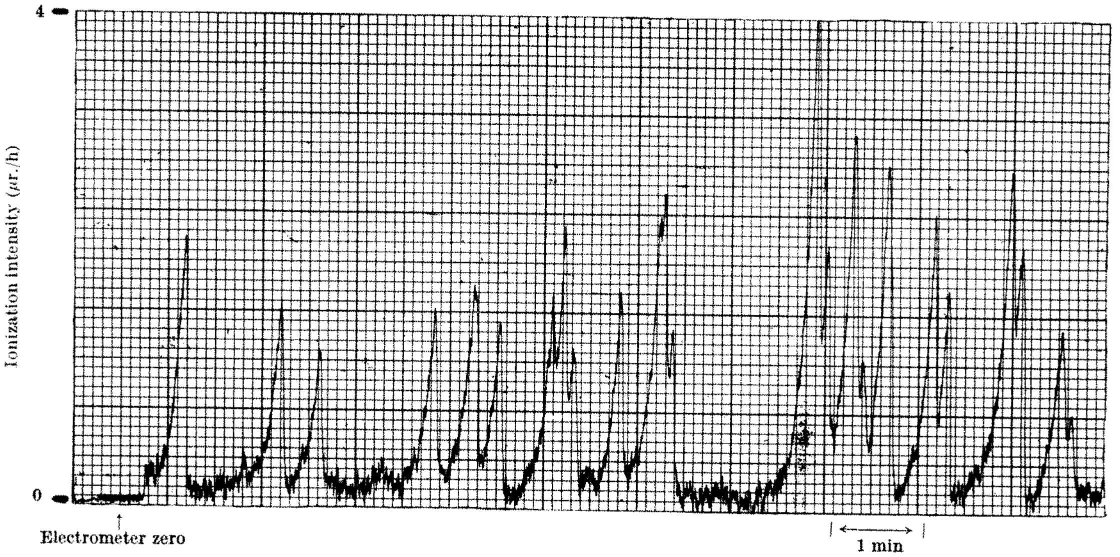

Fig. 1. Intensity of background ionization in the Red Mountain mine, showing the effect of wall alphas.

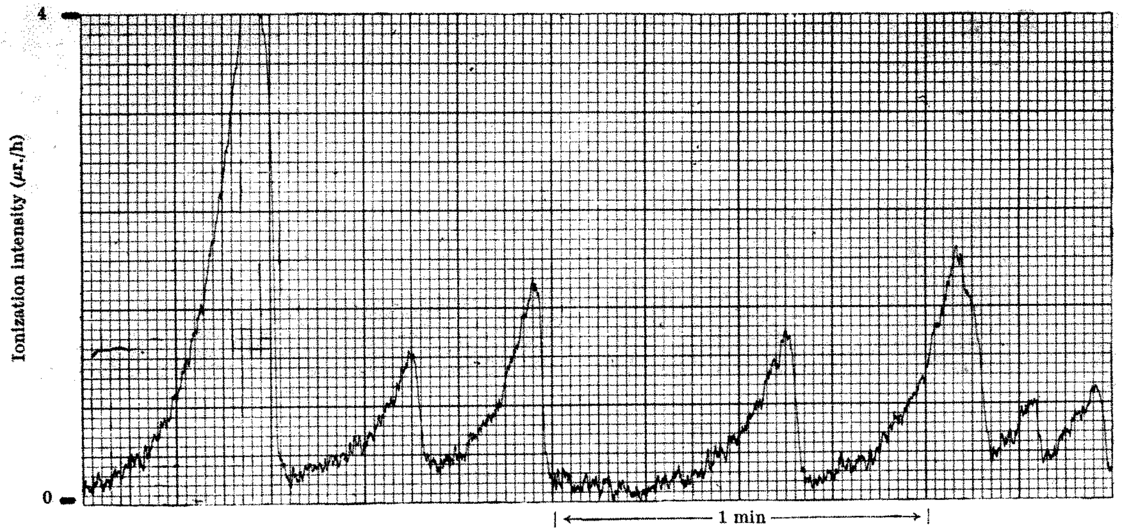

Fig. 2. The resolution of alpha activity in an ionization chamber.

As an example of the sort of experiment which could be carried out in the Red Mountain mine or, for that matter, in the mines in the Thetford region of Quebec, it has been shown[19] that certain anomalous results in the cosmic ray depth-intensity relation below ground[20] can be explained as resulting from multiple Geiger counter coincidences caused by local gamma radiation. A substantial decrease in local background would enable such work to be carried out with much less shielding, which, as an added benefit, would yield more data about the low energy end of the underground cosmic ray spectrum. Cosmic ray surface measurements could probably be performed over such regions with little or no shielding, and with perhaps little in the way of anticoincidence protection. Other possibilities include the use of such areas for research in those problems in genetics and archaeological dating where very low background levels are required.

PHYSICS

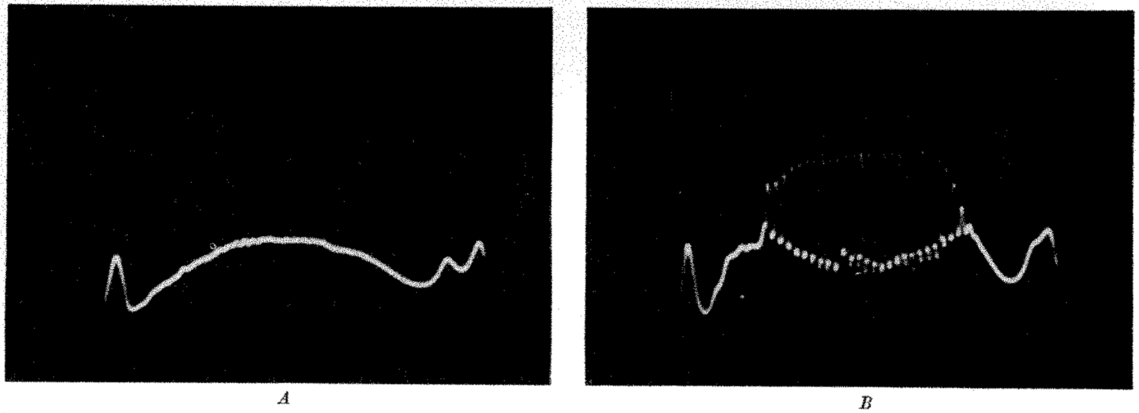
Stimulated Emission and Laser Action from the Organic Ligand of Gadolinium Chelates

WE wish to report evidence for stimulated emission and laser characteristics from liquid solutions of gadolinium organic chelates at room temperature. To our knowledge this is the first time that electronic transitions in organic chromophores have performed laser action under direct flash in liquid solution. The stimulated emission is reproducibly obtained at room temperature in conditions in which no fluorescence or phosphorescence is usually detected. With identical pumping energy, the coherent emission from the organic ligand in the Gd chelate is comparable with that obtained from solutions of europium[1-3] and terbium[4] chelates in which the emitting species is the complexed lanthanide ion.

Three gadolinium chelates exhibited laser action at room temperature in solution: *tris*(theonyltrifluoroacetonate)-Gd III (GdT$_3$), α,α′-dipyridyl-*tris*(theonyltrifluoroacetonate)-Gd III (GdT$_3$Dipy), and 1,10-phenanthroline-*tris*(theonyltrifluoroacetonate)-Gd III (GdT$_3$Phen). The procedures for their preparation have been described previously[5-7]. Solutions of 1×10^{-3}–3×10^{-3} M in spectrograde acetonitrile (Columbia Organic Chemicals) were prepared and tested for laser action at room temperature. Removal of oxygen (deaeration) or prolonged storage did not significantly change the laser performance of the material.

The liquid laser cavities and the alignment techniques employed in this work have been described in detail before[4,8].

Fig. 1 shows the relaxation oscillations (spiking) observed above threshold from GdT$_3$Dipy in acetonitrile. The optimum concentration (lowest threshold) was found to be around $2{\cdot}5 \times 10^{-3}$ M for GdT$_3$Dipy, the most efficient of the three chelates reported here. The spectral distribution of the laser lines is displayed in Fig. 2. The broad band centred at 394 mμ is caused by the background light from the xenon flash lamp corresponding to a "window" in the filter system and is easily reproduced when the liquid cell is empty or filled with pure solvent. The very narrow laser lines are superimposed on the background emission. Beam collimation has also been observed above threshold on far-field images of the output obtained on Polaroid film. These results are reproducible.



A *B*

Fig. 1. Relaxation oscillations in the output of the GdT_3Dipy laser, $2·5 \times 10^{-3}$ M, in acetonitrile at room temperature. *A*, Oscilloscope trace below threshold, 100 μs/cm sweep; *B*, same, above threshold.

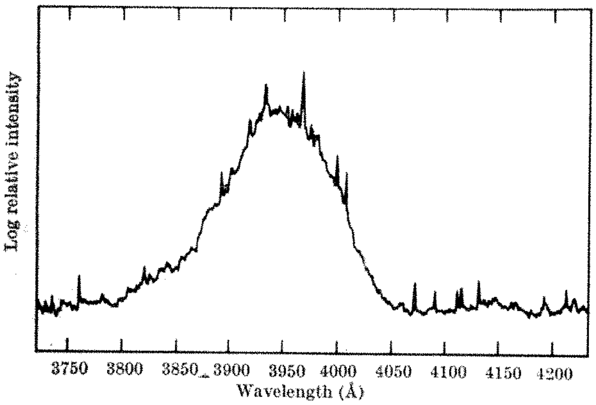


Fig. 2. Microdensitometer trace of the spectral output from the GdT_3Dipy laser. The broad band centred at 3940 Å is from the flash lamp; the narrow laser lines are superimposed on the background.

The same solution can be flashed repeatedly up to about twelve times before its laser activity diminishes. Between the flashes we allowed several minutes for cooling by equilibration with environmental temperature. The time elapse between flashes can be reduced using external cooling with cold nitrogen gas or recirculation[8].

There are at least fourteen clearly defined laser transitions detectable in the spectral range 3750–4200 Å. At present we are unable to make definite assignments of these transitions, but a brief discussion of the existing possibilities is warranted. The stimulated emission does not originate in the Gd^{3+} ion, which has the lowest resonance level at about 32,100 cm^{-1}. Emission spectra of the chelates investigated in this work have been reported recently[7]. The phosphorescence and phosphorescence excitation spectra illustrated in Fig. 3 were obtained in rigid matrix (EPA) at liquid nitrogen temperature. A detailed analysis of Fig. 3 can be found in ref. 7. It is obvious that the laser lines do not coincide with the phosphorescence of either T or Dipy chromophores (curves *A* and *C*, respectively). But the triplet–singlet emission in Fig. 3 was obtained in a different environment and at much lower temperature. It is possible that in acetonitrile the lowest triplet of the Dipy ligand is destabilized more than the ground singlet, in which case the laser lines would correspond to stimulated emission originating at the lowest triplet in the Dipy chromophore. The $n \rightarrow \pi^*$ transition in some compounds has been blue-shifted as much as 725 cm^{-1} in acetonitrile[9]. Nothing is known about the polarity or solvation properties of the excited states in the Gd chelate. But the possibility of a hypsochromic shift of the $0 \rightarrow 0$ band in the Dipy phosphorescence such as to overlap with the observed laser lines cannot be ruled out. Usually only very few compounds exhibit phosphorescence in liquid solution because of collisional deactivation (or chemical reaction) by solvent molecules or other cosolutes. This is a result of the relatively long lifetime of the lowest triplet. In a Fabry Perot resonator, however, the population inversion attained under a powerful flash may well lead to a stimulated radiative deactivation of the triplets.

The second alternative seems to be a stimulated emission from the lowest excited singlet in the T chromophore, for the lines in Fig. 2 could form a "mirror image" band with the excitation (absorption) curve *D* in Fig. 3. Nonetheless, we do not consider this alternative very probable because the rate of intersystem crossing in aromatic β-diketones is several orders of magnitude above the rate of emission from S_1, and in Gd chelates the crossover to the triplet should be even faster.

The third possibility is a photochemical process in which the intermediate or product is formed in an excited state which can be the origin of the lasing transitions. The decrease in lasing activity after repeated (about ten to twelve times) flash pumping tends to support this possibility. But the same effect may be the result of other photo-degradative processes.

The vibrational structure of the lines in Fig. 2 cannot be satisfactorily correlated with the absorption and emission spectra of the two organic ligands in the infrared (and Raman) and ultraviolet-visible. We are also considering the energy transfer between the two different

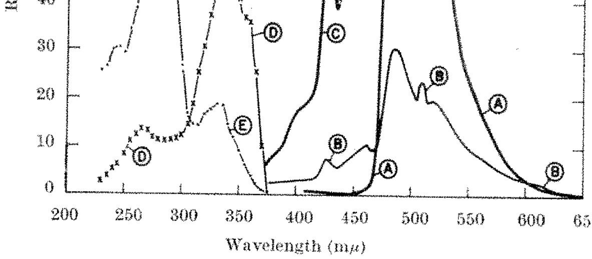

Fig. 3. Phosphorescence and excitation spectra of GdT_3Dipy 10^{-5} M in ethanol-2-methylpentane-ether (EPA) at 77° K: (*A*) phosphorescence of T excited at 345 mμ where only T absorbs; (*B*) excitation at 234 mμ in the Dipy absorption band, emission from both Dipy and T chromophores; (*C*) Dipy phosphorescence excited at 280 mμ; (*D*) excitation (corrected) of the T phosphorescence at 489 mμ; (*E*) excitation (corrected) of the Dipy phosphorescence at 426 mμ.

ligands[7] as well as other flash-induced alternatives in a detailed study to elucidate the origin of the lasing transitions.

Cavitation induced by Vorticity at a Smooth Flat Wall

An interesting example of cavitation, apparently induced by vorticity, has arisen at the plane side walls of a small cavitation tunnel during studies primarily concerned with the behaviour of large cavitating eddies.

A cylinder in a water tunnel has been made to generate, at high frequency and from alternate sides, a stream of cavitating eddies[1]. When viewed under stroboflashing light, cavitation bubbles are seen to stem from one or other side of the cylinder and in each case are carried by the stream into a rapidly growing but relatively short-lived eddy with a large amorphous central cavity. Each elongated, large-cavity eddy ultimately becomes detached from the cylinder; the amorphous core subsides quickly into two (or occasionally more) minor eddies of high angular momentum and each of these eddies briefly sustains a mist, or cloud, of minute cavities. Eventually each cloud collapses with extreme rapidity and may cause severe damage at adjacent boundaries[1].

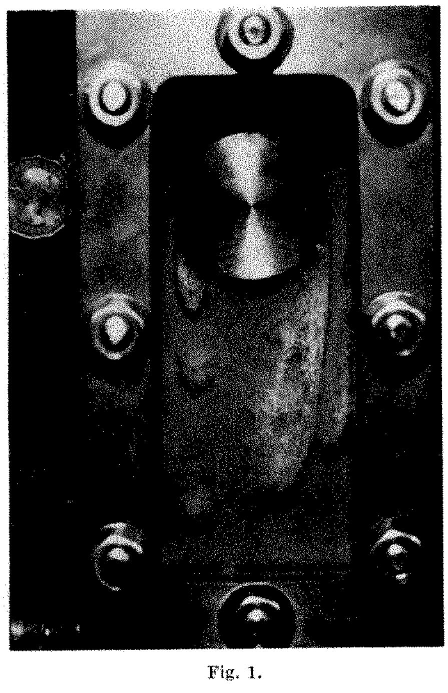

Fig. 1.

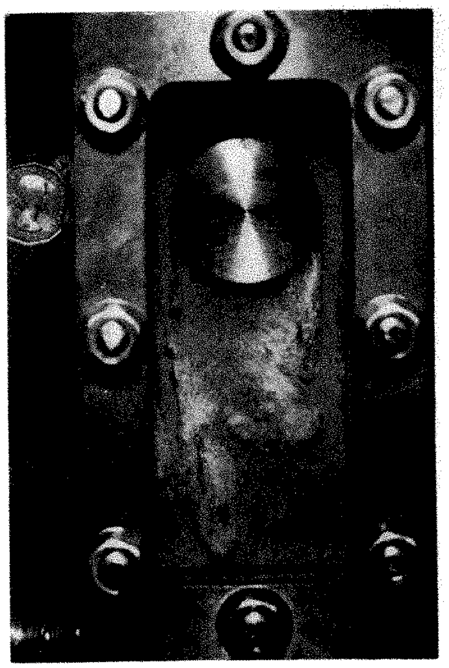

Fig. 2.

With the formation of each of the large cavity eddies, additional (and concurrent) cavitation has been observed, downstream of the cylinder, at the tunnel side wall adjacent to the large-cavity eddy. Flow is contained momentarily by the tunnel wall and by the free streamline of the large-cavity eddy. The free streamline, which is at cavitation pressure, curves away from the tunnel wall and the radial pressure gradients associated with the eddy might therefore be expected to keep the tunnel wall pressures above cavitation pressure. But substantial vorticity seems to be generated within the boundary layer at the tunnel wall and it seems that this vorticity is responsible for the low pressures actually occurring near the tunnel wall and observed by means of the induced tunnel-wall cavitation.

Figs. 1 and 2 show cavitation induced by vorticity near the tunnel walls downstream of the cylindrical obstruction. In this test, water at 66·5° Fahrenheit flowed past a 1·50 in. diameter cylinder in a tunnel which was 9 in. long and $2{\cdot}00 \times 0{\cdot}25$ in. in cross-section. The measured eddy-shedding cycle frequency was 6,600/min when the water approached the cylinder with a mean velocity of 17·2 ft./sec and a pressure of 74·7 ft. of water (absolute).

Tunnel-wall cavitation with associated cylinder-wake cavitation has also been observed (for example, Fig. 3) in the relatively steady flow situation obtained by closing one of the flow passages between the cylinder and the tunnel side walls. It thus seems that cavitation can be induced at a plane surface by the vorticity generated within the boundary layer and the vorticity may be detected and viewed, for example, under stroboflashing light, by its induced cavitation.

Cavitation inception at the centre of a boundary layer near a smooth wall has been reported by Daily and Johnson, who found that such cavitation always occurred when the wall pressure was greater than the water vapour pressure. This was attributed to pressure reductions in the boundary layer caused by vortical eddies and turbulence[2]. Arndt and Ippen have also observed cavitation inception in the centres of turbulent boundary layers at

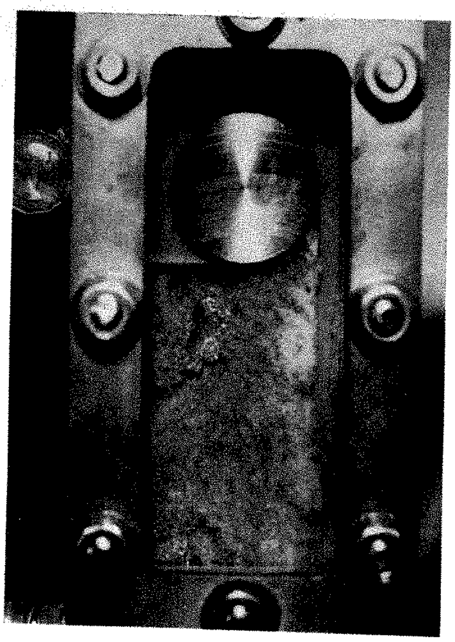

Fig. 3.

smooth and rough surfaces and have correlated the cavitation inception with the wall shear[3]. Cavitation has also been observed and studied at other regions of high shear, for example, by Rouse in the mixing zone of a submerged water jet[4]. Such regions of shear generate vorticity and may therefore be expected to produce local zones of low pressure and, in appropriate conditions, cavitation.

THE SOLID STATE

Mechanisms of Fatigue Damage in Face Centred Cubic Metals

The work of Wood *et al.*[1,2] has shown that fatigue damage occurs by different mechanisms in different regions of the *S/N* curve, these being designated as the *H* mechanism at high stress levels where fatigue life increases slowly with decreasing stress amplitude, and the *F* mechanism at lower stress levels where fatigue life increases rapidly with decreasing stress. There is also a pseudo-safe or *S* region. A number of workers[3-6], however, have suggested that there is a less clear-cut distinction between the mechanisms occurring at the different stress levels than the results of Wood *et al.* indicate, and we discuss here the role of material properties such as texture and ductility on the operative mechanisms of fatigue damage.

Fatigue tests have been carried out on three face centred cubic (FCC) materials, an aluminium–magnesium alloy (Alcan *CA*-57*S*), 99·99 per cent pure aluminium, and electrolytically pure tough-pitch copper, the plate being first cold-rolled by approximately 90 per cent to obtain sheets with a high degree of preferred orientation, the texture approximating to the $\{110\}<112>$ ideal orientation. Sheet with cube texture ($\{100\}<001>$) was produced by annealing the cold-rolled, high-purity aluminium and the copper, and material with a random texture by annealing the cold-rolled 57*S* alloy. Fatigue tests were made on all materials, the specimens first being carefully finished and checked to ensure that they were free from scratches. Stressing was by reversed bending and tests were made over a wide range of stress levels. After testing to failure, the specimens were examined under the optical microscope to determine the nature of the fatigue damage which had occurred.

The damage to the cold-rolled material tested at high and low stress amplitudes occurred by the formation of sub-boundaries and pores corresponding to Wood's *H* mechanism normally found at high stress amplitude, and Fig. 1 shows such damage on the surface of a sample of high-purity aluminium tested at a low stress amplitude, the photograph having been taken some distance from the main crack. In this sample the surface has been electro-polished and lightly etched to show the structure more clearly. It was noted that the fatigue cracks, which developed by the continued production and linking of the pores, propagated in a direction approximately normal to the specimen axis in all the cold-rolled samples. In the sheet metal specimens with cube texture, fatigue damage at all stress amplitudes occurred along slip bands, which broadened until cracks formed and propagated at approximately 45° to the specimen axis. This corresponds to Wood's *F* mechanism, and the surface of a specimen of annealed high-purity aluminium tested at a high stress amplitude and exhibiting damage along slip bands is shown in Fig. 2: again the specimen has been electro-polished and lightly etched and the region shown is some distance from the fracture. It is also of interest that the annealed material with random texture did not show a distinct difference between the mechanisms of fatigue at high and low stress levels, damage occurring predominantly by the *H* mechanism at high stress and by the *F* mechanism at low stress with a gradual transition at intermediate stress levels. The observations made from all the tests are summarized in Table 1, the high and low stress levels being defined in terms of the number of cycles to failure (*N*).

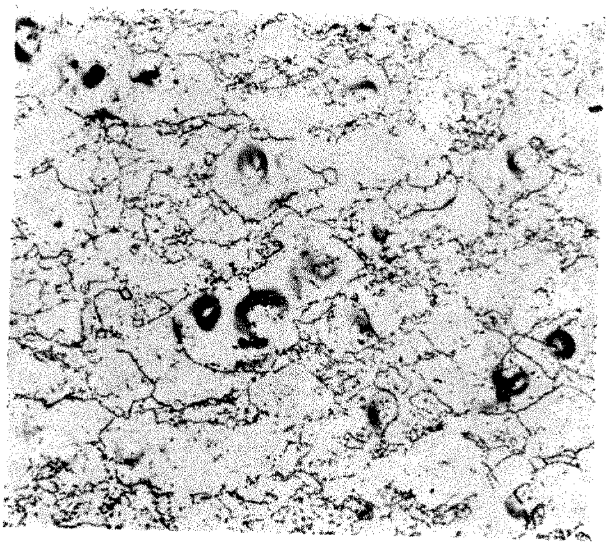

Fig. 1. Cold-rolled, high-purity aluminium fatigued at a low stress amplitude showing Wood's *H* mechanism of fatigue damage (× 240).

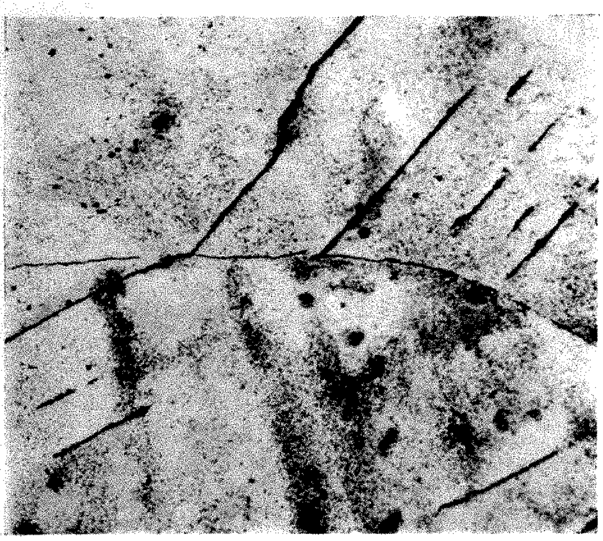

Fig. 2. Annealed, high-purity aluminium fatigued at a high stress amplitude showing Wood's *F* mechanism of fatigue damage (× 240).

The results indicate that there is not necessarily a correlation between high stress amplitude and *H* mechanism, and low stress amplitude and *F* mechanism, and that the operative mechanisms of fatigue damage may be influenced to a great extent by texture and ductility. Although it is difficult to assess the separate effects of these two factors, because the ductility depends on texture to a large extent, it may be seen from Table 1 that the annealed aluminium 57*S* with random texture and the annealed high-purity aluminium with cube texture have similar ductility, but the fatigue damage at high stress occurred predominantly by the *H* mechanism in the former and by the *F* mechanism in the latter. We are now making a more detailed correlation between fatigue mechanisms and texture.

Table 1

Material	Condition	Tensile ductility (% elongation at fracture)	Texture	Fatigue damage mechanism	
				High stress ($N = 10^4$–10^5 cycles)	Low stress ($N = 10^6$–10^7 cycles)
Al 57*S*	Cold-rolled 93%	6	{110} < 112 >	*H*	*H*
Al 57*S*	Annealed	28	Random	*H* > *F*	*F* > *H*
Al (99·99%)	Cold-rolled 90%	6·5	{110} < 112 >	*H*	*H*
Al (99·99%)	Annealed	30	{100} < 001 >	*F*	*F*
Cu (tough pitch)	Cold-rolled 90%	6	{110} < 112 >	*H*	*H*
Cu (tough pitch)	Annealed	49	{100} < 001 >	*F*	*F*

MOLECULAR STRUCTURE

NMR Studies of Gramicidine *S* in Solution

GRAMICIDINE *S* is a cyclic polypeptide containing ten amino-acid residues arranged in two identical groups. This molecule has attracted considerable interest as a model related to the more complex globular proteins.

Recently attempts have been made[1,2] to derive a model of gramicidine *S* on the basis of energy considerations. The two models are schematically drawn in Fig. 1*a*, *b* and *c*. The two conformations are markedly different in spite of the similar overall shape and dimensions of the molecules. The difference probably arises because the energy criterion was applied in different ways. Sheraga *et al.* have tried to calculate the potential energy of the molecule as a function of all the angles of rotation about the non-conjugated bonds (including the side chains), but Liquori *et al.* used their own stereochemical code for the amino-

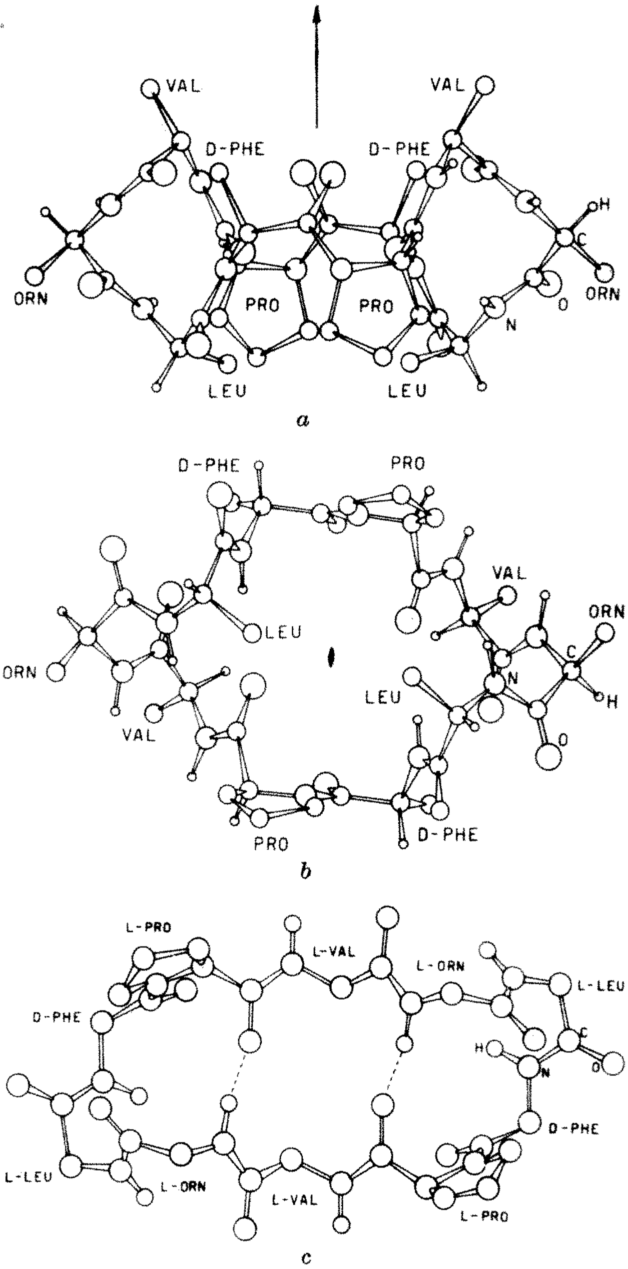

Fig. 1. Models of the molecule of gramicidine *S* due to Liquori *et al.*[1] (*a*) and (*b*) and Sheraga *et al.*[2] (*c*).

acid residue with standard bond lengths and bond angles* which can only have five conformations defined by the angles of rotation $\Psi_{C\text{-}C}$, $\Psi_{N\text{-}C}$, $\omega_{C\text{-}N} = 0$, about the skeleton bonds Cα–C, N–Cα, and C–N. These conformations are indicated by *Ra*, *b*, *c*, *d*, *La* for an L-residue (or Ra^+, b^+, c^+, d^+, La^+ for a D-residue). Identical repetitions of these five conformations generate the five helices *R*α, β, γ, δ, *L*α energetically allowed for a homopolypeptide chain.

The problem of deriving the conformation of gramicidine *S* was therefore treated as a "stereochemical translation" which involves assigning to each amino-acid residue a "stereochemical codon" with the restrictions imposed by the closure of the ring and by the condition of conformational equivalence between identical residues. As a result the skeleton of the molecule was "coded" as follows

$$\begin{array}{ccccccccc} d & & Ra & & Ra & & Ra & & c^+ \\ \text{Pro} & - & \text{Val} & - & \text{Orn} & - & \text{Leu} & - & \text{DPhe} \\ | & & & & & & & & | \\ \text{DPhe} & - & \text{Leu} & - & \text{Orn} & - & \text{Val} & - & \text{Pro} \\ c^+ & & Ra & & Ra & & Ra & & d \end{array}$$

The two segments Val–Orn–Leu can therefore be described as two anti-parallel right handed α-helical segments which are connected by two "non-helical" segments DPhe–Pro. Two hydrogen bonds between the C=O groups of two Val and the N–H groups of the two DPhe are present in this structure as in an α-helix. As well as testing this conformation by X-ray diffraction, we have carried out NMR studies in solution. One aim of this investigation was to estimate the relative ability of the peptide hydrogens present in the molecule to exchange for deuterium. Furthermore, we have tried to obtain NMR data about the correctness of our stereochemical codification of the skeleton of gramicidine *S*. This test is based on the very close similarity between the local conformation of an amino-acid residue of gramicidine *S* corresponding to a given stereochemical codon in the proposed model and that of the same amino-acid residue in the corresponding helix. It has been shown (unpublished work of Liquori, Conti and Ferretti) that the chemical shift of a CH proton in a homopolypeptide seems to be strongly dependent on the backbone conformation of the amino-acid residues, to a smaller extent on the nature and conformation of the side chains, and it is fairly insensitive to the solvent. Thus the chemical shift of the CHα of α-helical poly-L-leucine, α-helical poly-L-ornithine and δ-helical *trans* poly-L-proline (polyproline II) should not differ much from the chemical shifts of the CHα protons of leucine, ornithine and proline residues in gramicidine *S*, which, according to our model, should have local conformations *Ra*, *Ra* and *d* respectively.

The preliminary results obtained on a sample of gramicidine *S* (Mann Research Lab.) using an *HA* 100 Varian NMR spectrometer are summarized here.

(*a*) *Deuterium exchange experiments*. In Fig. 2 are shown the NMR spectra of gramicidine *S* recorded in pure dimethylsulphoxide (DMSO) and 10 min after addition of different amounts of D_2O and trifluoroacetic acid. This region contains peaks corresponding to phenyl and NH protons. The CH protons of the benzene rings of the two groups of DPhe (7·25 p.p.m.) are magnetically equivalent This effect implies that the two rings are probably free rotating in solution and is fully compatible with the presence of a dyad axis relating the two amino-acid residues. In pure DMSO, the NH protons give rise to three different signals respectively at 8·05, 8·30 and 8·60 p.p.m., which are called HN_I, NH_{II} and NH_{III}. It can be deduced from the peak areas that the ratio $NH_I : N_{II} : NH_{III}$ between these peaks is 4 : 2 : 2. The low peak at ~9·1 p.p.m. is probably caused by an impurity, as may be judged from the value of the peak area and from the unusual chemical shift. On progressive additions of D_2O, the peak NH_I tends to disappear, and in the presence of traces of trifluoroacetic acid the peak NH_{II} also disappears and NH_{III} is the only peak left. There are therefore two equivalent NH protons which exchange at a significantly slower rate than the others. Such a conclusion is fully consistent with our model of gramicidine *S* which contains two hydrogen bonded NH groups. It should, however, be noted that this does not rule out Sheraga's model, as can be seen in Fig. 1*c*. The NH_I peaks at higher field might be identified with the NH protons of two Leu and two Orn residues in Liquori's model which are less accessible and the NH_{II} peak might be identified with the NH protons of two Val residues which are more readily accessible and are magnetically equivalent.

(*b*) *Tentative assignments*. The 0–5 p.p.m. region of the NMR spectrum of gramicidine *S* in DMSO is shown in Fig. 3. The positions of the peaks corresponding to the protons in the NMR spectra of α-helical leucine and ornithine and of polyproline II (δ-helical) (unpublished results) are indicated schematically at the top of Fig. 3. It can be seen that the position of the CHα peak of polyproline II agrees very closely with the band at 4·80 p.p.m. in gramicidine *S* which according to the integral of the peak area contains two protons. The positions of the CHα peaks of α-helical poly-L-leucine and poly-L-ornithine fall within the band at 4·25 of the NMR spectrum of gramicidine *S*.

This peak corresponds to six protons and the shoulder, and so at a lower field (at 4·50) corresponds to two protons; the assignment of the two CHα protons of Phe and of the two CHα protons of Val presents some ambiguity.

It should be mentioned that the addition of $CDCl_3$ gives better resolution of the αCH regions in gramicidine *S* and that the shoulder at 4·50 becomes much more obvious. There is, however, a strong indication that an intermolecular association takes place and this is being studied.

This preliminary assignment therefore seems to be consistent with Liquori's model of gramicidine *S*, and we hope to reach more definite conclusions on the basis of NMR spectra at higher resolution.

Very little can be said about the consistency of Sheraga's model with the αCH proton region of the NMR spectra of gramicidine *S* because of the lack of data concerning suitable reference systems. The marked broadness of all CH protons, except the phenyl and methyl protons, which is commonly observed in the NMR spectra of α-helical homopolypeptides in solution, however, is in more general agreement with a compact conformation like the Liquori model than with an open structure like the Sheraga model.

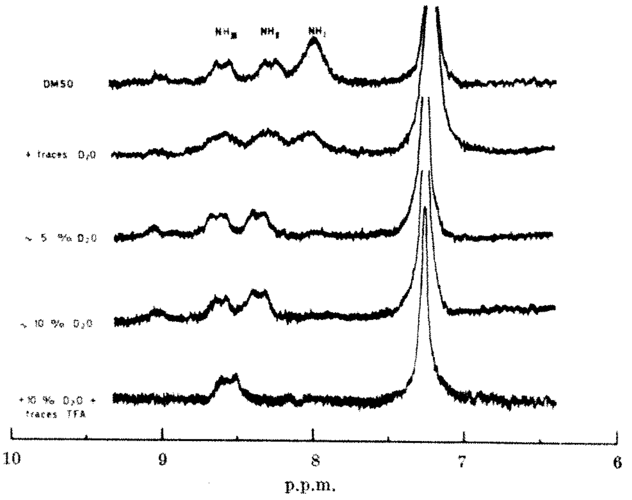

Fig. 2.

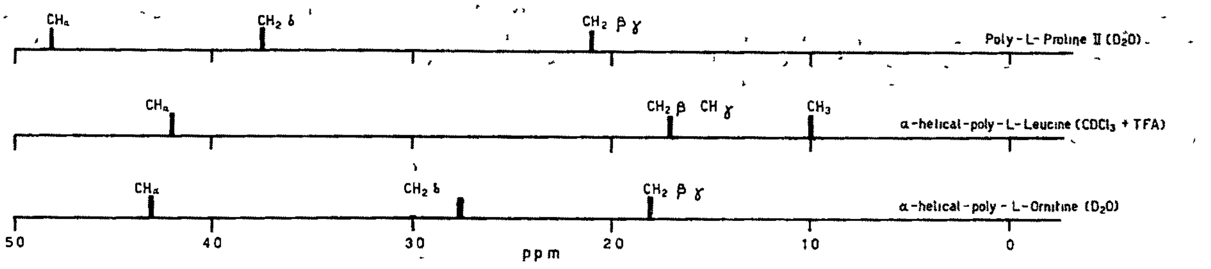
---

* Whereas previously[1] the best set of Corey and Pauling[3] for the bond angles and bond lengths could be adopted for all the amino-acid residues, the model has now been slightly refined by using bond angles found by Leang and Marsh[4] for the geometry of the L-proline residues (unpublished work of Liquori and Santis).



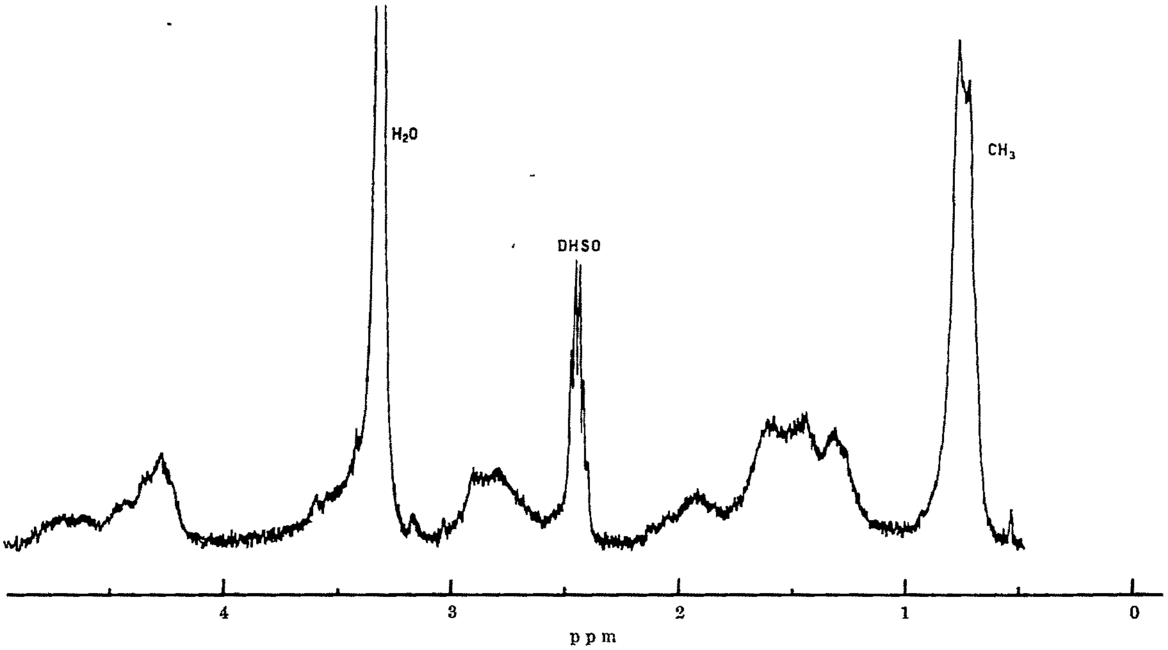


Fig 3

All our conclusions therefore contrast with those of Balasubramanian[5] and are in line with the results of optical rotation studies[6] It should, however, be mentioned that Balasubramanian's discussion of the experimental results reveals that he has not inspected the molecular models Typical in this connexion is the claim that Liquori's model is not compatible with the infrared data, because it contains peptide bonds in a *cis* conformation, which is not true[1]

The NMR experiments were carried out at the Istituto Superiore di Sanità We thank Dr G Conti for technical assistance

Note added in proof A recent calculation of the chemical shifts of the protons of gramicidine *S* carried out in our laboratory (to be published) gives results which confirm this tentative assignment of the NMR spectra according to Liquori's model and seem to be entirely inconsistent with Scheraga's model

CHEMISTRY

Laser Raman Spectra of Sorbed Species

WE have previously reported[1] that spectra of adsorbed species can easily be obtained with a laser excited Raman spectrometer We now wish to extend the field to the case in which there is the possibility of chemisorption

Young and Sheppard[2,3] have used infrared techniques to study a series of aliphatic aldehydes adsorbed onto silica gel and have concluded that at room temperature they are, at least initially, physically adsorbed Spectra obtained after desorption were not identical with those of the clean gel They showed neither aldehydic ν C—H nor carbonyl ν C=O bands and were considered to be caused by a new surface species It was thought that two distinct types of species might be formed, the first of these would have an alkoxide type structure (Fig 1) and the second would be either a linear or cyclic polymeric aldehyde, but Young and Sheppard were unable to discriminate between the various possibilities

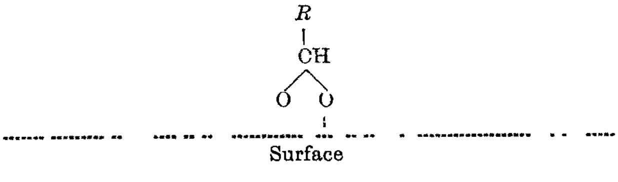

Fig 1

Using the sampling arrangements described earlier[1], we have investigated the Raman spectrum of acetaldehyde adsorbed onto silica gel The spectrum showed seven bands between $\Delta\nu = 80$ cm^{-1} and 2,000 cm^{-1}, none of which were found to coincide with the emissions caused by liquid acetaldehyde[4] and in particular the absence of the carbonyl ν C=O band at 1,720 cm^{-1} was most noticeable (Table 1)

Table 1

* Due to the instrument[5]

The spectrum was found to resemble that due to paraldehyde (Fig 2) because the stronger emissions of this cyclic molecule occur in the adsorbate–adsorbent system Subsequent desorption into a cold trap produced a liquid the spectrum of which is consistent with the circumstance of it being a mixture of acetaldehyde and paraldehyde

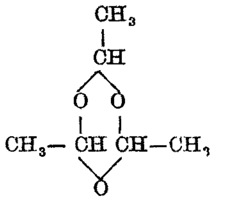

Fig 2.

Although overall similarities between the spectra of the structures shown in Figs 1 and 2 would be expected, the close resemblance between the spectra of paraldehyde and the adsorbate–adsorbent system strongly suggests that condensation of acetaldehyde has been catalysed at the surface, leaving a physically adsorbed cyclic product

It may be objected that the laser beam itself could raise the temperature of the sample locally and evaporate off the adsorbate and its reaction products This possibility has been discussed[1], but it is considered significant that the spectrum of the adsorbed layer is not identical with that of the distillate and bands characteristic of the volatile acetaldehyde are absent from it

It is evident that the use of Raman spectroscopy has considerable potential in the study of adsorbed species The small amount of interference from the substrate does not prevent the convenient recording of data over a wide and continuous frequency range ($\Delta\nu = 3,600$ cm^{-1} to 80 cm^{-1})

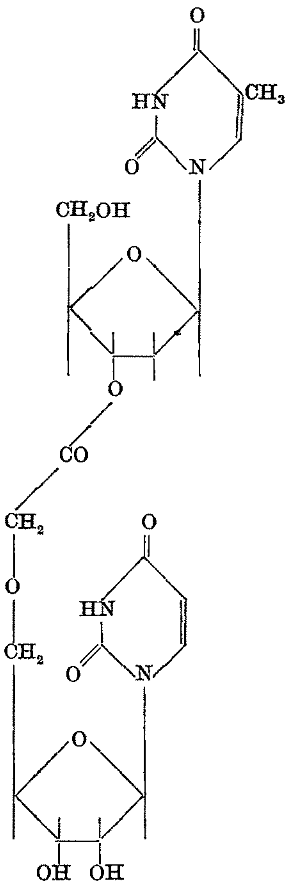
Synthetic Analogues of Polynucleotides

Analogues of purines and pyrimidines have been used as antimetabolites[1] Some of these have been converted into their nucleosides or nucleotides which also act as antimetabolites[2] Analogues of nucleosides in which D-ribose or 2-deoxy-D-ribose is replaced by another carbohydrate or carbohydrate analogue have also been extensively studied[2] Some of the nucleotide analogues have been converted into polynucleotide analogues by the use of suitable enzymes[3–6] and by taking advantage of the fact that certain micro-organisms will incorporate the nucleotide analogue into DNA or RNA (refs 7–13) The synthesis of polynucleotide analogues in which the purine or pyrimidine side chains are linked by a type of backbone different from the sugar phosphate backbone of the natural polynucleotides has been reported in previous work from this laboratory One type was obtained by copolymerizing 5′-*O*-acryloyluridine with acrylamide[14] and another by reacting adenosine dialdehyde with polyacrylic acid hydrazide[15] Both these polymers contained a fraction which hybridized with denatured DNA trapped in agar and with denatured DNA in solution

Another type of polynucleotide analogue is one in which the carbohydrate and purine and pyrimidine bases are the same as those of natural polynucleotides but in which the internucleoside linkage is not a phosphodiester linkage A dinucleoside phosphate analogue of this type has been synthesized in which the nucleoside units were linked by a phosphorothioate group[16] We were interested in synthesizing analogues in which the linkage between the nucleoside units was a carboxylic ester linkage This would give an uncharged molecule which might be expected to penetrate membranes of living cells more easily than a charged oligonucleotide From the chemical point of view, one of the easiest types of monomeric derivatives to prepare seemed to be the carboxymethyl derivatives of the nucleosides The linkage obtained by joining units of this type contains one more atom than does the phosphodiester linkage Examination of molecular models has shown, however, that the carboxymethyl ester linkage is fairly flexible so that the nucleoside units can become similarly spaced to those of the natural polynucleotides (7 1 Å) (ref 17)

As a first stage, an analogue of a dinucleoside phosphate was synthesized The carboxymethylnucleoside chosen was 5′-*O*-carboxymethyl-2′,3′-*O*-isopropylidineuridine (I) This was obtained as the sodium salt by treating the disodio-derivative of 2′,3′-*O*-isopropylidineuridine with sodium chloroacetate in dimethylsulphoxide In addition to the desired product, small amounts of 3-carboxymethyl-2′,3′-*O*-isopropylidineuridine (II) and 3-carboxymethyl-5′-*O*-carboxymethyl-2′,3′-*O*-isopropylidineuridine were formed If the monosodio-derivative of isopropylidineuridine was used the major product was II I, as the pyridinium salt, was condensed with 5′-*O*-tritylthymidine in the presence of dicyclohexylcarbodiimide and the trityl and isopropylidine protecting groups removed with 80 per cent acetic acid to give the dinucleoside phosphate analogue, 3'-*O*-(uridin-5'-yl-glycollyl)-thymidine (III).

III had λ_{max} 264 mμ in 0.01 N hydrochloric acid and an extinction coefficient of 18.3×10^3. The corresponding value for 5'-*O*-carboxymethyluridine (obtained from I by removal of the isopropylidene group with dilute acid) was 10.3×10^3, and those for uridine and thymidine were 10.1×10^3 and 9.65×10^3, respectively. Thus the extinction coefficient of III is 7–8 per cent lower than that calculated by summation of the corresponding values for the constituents of the molecule. This hypochromic effect is larger than that of about 3 per cent found for dithymidine phosphate in acid solution[18], and greater than the value of about 5 per cent found for polyuridylic acid[19]. This can be explained by the fact that the internucleoside linkage in III is more flexible than the phosphodiester linkage and therefore allows greater interaction between the bases than is the case with the oligonucleotides. It may be noted that the hypochromic effect for p^1,p^2-diadenosine-5'-pyrophosphate is considerably greater than that for diadenylic acid and that this has been attributed to the same effect[20].



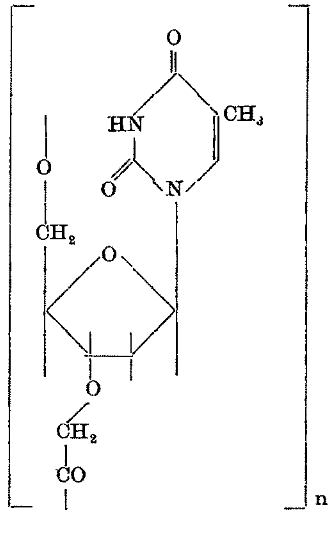
III

3'-*O*-(uridin-5'-yl-glycollyl)-thymidine

Solutions of III and polyadenylic acid in buffer, *p*H 6.3, of various ionic strengths showed no hypochromic effect when mixed. This result was not surprising because thymidine-containing oligonucleotides of chain length less than five showed no hypochromic effect with polyadenylic acid[21].

Because of these results we decided to synthesize a polymer of a carboxymethylnucleoside. We used 3'-*O*-carboxymethylthymidine, which was obtained as follows. The disodio-derivative of 5'-*O*-tritylthymidine was treated with sodium chloroacetate in dimethyl sulphoxide to give the sodium salt of 3'-*O*-carboxymethyl-5'-*O*-tritylthymidine (IV) as the major product. Some 3-carboxymethyl-5'-*O*-tritylthymidine was also produced.

The compound IV was obtained pure by fractional crystallization and the trityl group removed with dilute acetic acid to give 3'-*O*-carboxymethylthymidine. This was polymerized in the presence of a tenth molar proportion of IV (to act as a chain terminator) in concentrated solution in pyridine by the use of dicyclohexylcarbodiimide. The terminal trityl group was removed by treatment with dilute acetic acid, and the product dissolved in dimethylformamide, dialysed exhaustively against dimethylformamide and finally against water or salt solution to give a polymer of structure V. Although the solubility of the polymer in aqueous solution was low (about 4 μg/ml), this was sufficient for hybridization experiments with polynucleotides. The extent of hybridization was determined by measuring the hypochromic effect obtained on mixing solutions of the polymer with solutions of the polynucleotide. With polyadenylic acid a hypochromic effect of about 8 per cent was shown at room temperature in 1 M sodium chloride and in water, but there was no effect with polyuridylic acid or with denatured DNA.



V

A solution of the polymer in dimethylformamide was fractionated on 'Sephadex *LH*-20'. The results showed that part of the material was excluded and part just included in the gel. The material that was excluded therefore had a molecular weight greater than about 4,000. Both the fraction excluded from the 'Sephadex' and that included showed a hypochromic effect of 7–8 per cent with polyadenylic acid in water. A solution of the excluded fraction in water was allowed to stand at room temperature for two weeks. On refractionation in dimethylformamide solution on 'Sephadex *LH*-20', all the material was still excluded from the gel which showed that the polymer was stable in these conditions.

These results indicate that the polymeric thymine derivative was interacting with polyadenylic acid probably by means of specific hydrogen bonding as in the case of natural polynucleotides. An interesting feature was that this interaction occurred in water as well as in salt solution, in contrast with the natural polynucleotides which do not interact at low ionic strengths[19,22]. This suggests the possibility that polymers of this type might interfere with the function of messenger RNA in biological systems.

Laser Heating of Coal Particles in the Source of "Time-of-Flight" Mass Spectrometer

During general investigation of the processes that occur in the combustion of pulverized coal, experiments have been undertaken to develop methods for determining the nature of products formed by the rapid thermal decomposition of coal particles, especially those evolved in the very early stages of decomposition In previous work[1] the yields of the stable decomposition products evolved from small coal particles during the first millisecond of flash heating were determined by quenching the products in an inert atmosphere Using this method, however, it was not possible to determine whether free radical fragments constituted part of the primarily evolved species Recent work on the pyrolysis of lump coal using a laser beam has suggested that free radicals of molecular weight of about 100 are evolved[2], but in these experiments the products arose both from complete vaporization within the crater formed by the direct beam and from relatively slow low-temperature pyrolysis around this crater

In the experiments reported here, coal particles were heated in the source of a Bendix time-of-flight mass spectrometer and the spectra of the materials evolved have been recorded

A thin layer of particles of coal (Coal Rank Code No 902· C, 80 9, H, 4 8, O, 12 1 per cent dmmf basis), smaller than 10 μm in size, was placed on the upper polished end of a quartz rod that projected vertically through a vacuum seal in the base of the source-housing of the spectrometer, the upper end of the rod being located just below the ion grids of the source A ruby laser was mounted above the housing and the focused beam entered the source vertically through a quartz window and passed between the grids to strike the coal particles within a circular area of about 1 mm diameter The output from the laser was about 0 7 J which corresponded to a radiant flux falling on the surface of about 100 kW/cm² The weight of coal heated in this way was approximately 1 μg

The pyrolysis products from the coal travelled only about 1 cm in the high vacuum of the mass spectrometer before reaching the ionizing electron beam, thus minimizing the chance of secondary reactions occurring before analysis The mass spectra of the reaction products were shown on an oscilloscope and recorded using a high-speed drum camera, the interval between successive recorded spectra was 200 μs The first spectrum of the products of laser pyrolysis, recorded within 200 μs of the laser pulse, showed an unusual distribution of peaks that could not be satisfactorily explained by the cracking pattern of the low molecular weight decomposition products that are normally found in coal carbonization, and it was noted that the higher molecular weight materials normally found in coal tars were absent A typical example of such a spectrum, obtained at 70 eV, is shown in Fig 1*a* From this spectrum, and from others produced at lower electron energies, the following observations have been made about the nature of the initial products from the laser pyrolysis of the coal

(1) *Radicals and atoms* In the spectrum produced at an electron energy of 70 eV the peak at mass 15 (CH_3) was higher than that at mass 16 (CH_4); at the much lower electron energy of 13 eV (Fig 1*b*), at which the mass 16 has almost disappeared from the spectrum, the 15 peak persisted This suggests that the 15 peak is derived from methyl radicals and not from the cracking of CH_4 or methyl substituted hydrocarbons because at 13 eV the ionization voltage was too low to rupture the C—CH_3 or C—H bonds Similarly, the peaks at masses 1 and 2, which are caused by H and H_2, show a much higher mass 1/mass 2 ratio than is usual for molecular hydrogen The conclusion is that some of the mass 1 peak is caused by hydrogen atoms in the pyrolysis products The peak of mass 12 (carbon atoms) is too high to be accounted for by the cracking patterns of the hydrocarbons present and it is concluded therefore that carbon atoms generated during the pyrolysis also contribute to this peak

(2) *Polyacetylenes* The 26 peak, attributed to acetylene, is the principal hydrocarbon product and is accompanied by peaks at 50 (diacetylene) and two peaks

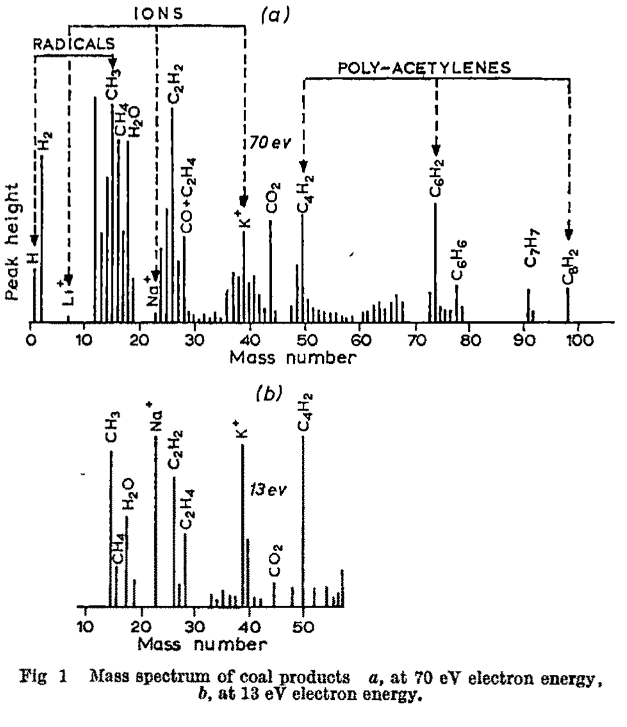

Fig 1 Mass spectrum of coal products *a*, at 70 eV electron energy, *b*, at 13 eV electron energy.

at 74 and 98 which are tentatively assigned to tri- and tetra-acetylene

(3) *Ions* The peaks at masses 7, 23 and 39 were detected even at zero electron energy and these are attributed to ions of the alkali metals, lithium, sodium and potassium Confirmatory experiments, in which carbon black and phenanthrene were heated with and without sodium and potassium salts, showed that these ions did not originate from the surface of the quartz rod

The results show that reactive species are evolved from coal on laser heating, but the temperature reached by the particles during the heat treatment is not known The height of the peak of mass 12 suggests the presence of a relatively high concentration of carbon atoms and indicates therefore that at some stage in the heating, temperatures of several thousands of degrees centigrade may have been reached The technique has, however, been shown to be suitable for detecting radicals and atoms, if present, and will therefore allow critical examination of spectra obtained by heating solids at a range of energies of laser radiation

We thank Professor J C Robb for many stimulating discussions

Preparation and Use of Porous Sheets with Enzyme Action

Two of the most important factors affecting the rate of catalysis by "insolubilized" enzymes are the rate of diffusion of substrate molecules from the bulk of the solution to the attached enzyme[1,2] and the interaction between the charged groups on the support material and the charged groups of the substrate molecules[3]

Many methods[4] are now available for coupling enzymes to insoluble supports, but they usually result in a support with a net negative charge Preparations of enzymes which attack neutral or negatively charged substrates such as ATP or NADH have activities which often seem to be low This is generally caused by electrostatic repulsion between the substrate and the support which results in the attached enzyme having a high apparent Michaelis constant compared with that of the free enzyme[1] It is therefore an advantage for such enzymes to be attached to supports with net positive charges In preparing these types of support, we have found that for attachment of enzymes to cellulose and cellulose derivatives it is an advantage if the net charge on the support is of opposite sign to that carried by the enzyme at the *p*H of attachment In most cases attachment is carried out in slightly alkaline medium (*p*H 7–9) Because the isoelectric points of many enzymes are less than *p*H 7, they are negatively charged above this *p*H and the support should therefore be positively charged

Kay and Crook[5] have attached chymotrypsin to mono and dichloro-*s*-triazinyl celluloses By modification of their technique it is possible to prepare support materials with net negative or positive charges and, if necessary, to alter the sign of the charge on the support after enzyme attachment, for example, by reacting the remaining chlorines of the support with a suitable amine Using the original method of Kay and Crook we have attached chymotrypsin to a dichloro-*s*-triazinyl cellulose paper (prepared from Whatman No 1 filter paper) and to a dichloro-*s*-triazinyl filter cloth To attach β-galactosidase and pyruvate kinase to these papers, however, it was first necessary to react the dichloro-*s*-triazinyl cellulose with a 0 2 N solution of N-(3-aminopropyl)-diethanolamine (Aldrich Chemical Co) at *p*H 7 0 for 7 5 min This results in a positively charged cellulose derivative It also has the effect of removing any free cyanuric chloride still remaining in the dichloro-*s*-triazinyl cellulose Very small amounts of cyanuric chloride can inactivate some enzymes presumably by reacting with certain groups (for example, sulphydryl) in their active sites After this pre-treatment, the paper was reacted with the enzyme for 10 min at *p*H 7 2 and 25° C

We have also attached β-galactosidase, creatine kinase and lactate dehydrogenase to chloro-amino-*s*-triazinyl derivatives of DEAE-cellulose paper (Whatman *DE* 81) Dichloro-carboxymethyl amino-*s*-triazine was reacted with *DE* 81 paper at *p*H 11 0 for 3 min and, after thorough washing at *p*H 2 0, the resulting product was reacted with β-galactosidase at *p*H 8 for 2 h at 25° C This technique was slightly modified for the attachment of creatine kinase Lactate dehydrogenase was attached to *DE* 81 paper by a similar technique (unpublished work) using dichloro-*s*-triazine 'Procion' dye 'Brilliant orange MGS' (Mayborn Products) The behaviour of these sheets has been investigated by passing substrates through them in various conditions Some examples are shown in Fig 1 All these preparations, with the possible exception of pyruvate kinase, were stable for at least several months

In most conditions, packed beds with enzyme action are theoretically more efficient than continuously fed stirred tanks for performing biochemical conversions[2] Porous sheets are a particular case of packed beds and have many operational advantages Reactors using several sheets stacked in series are easily set up and

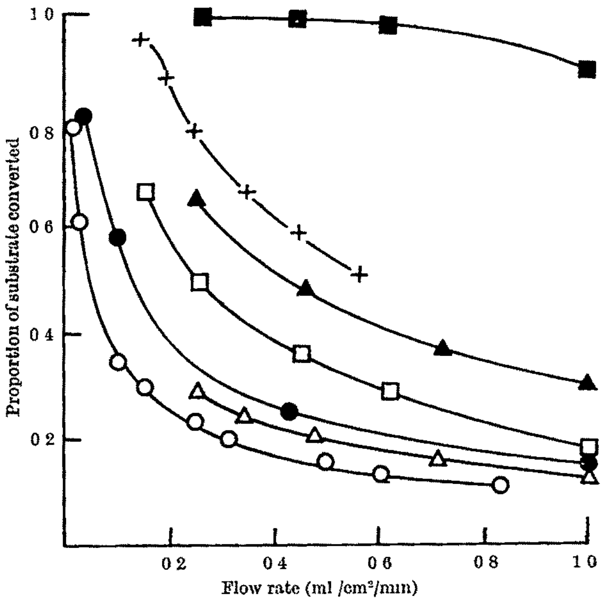

Fig 1 The effect of flow rate on the proportion of the rate-limiting substrate converted to product during passage through an enzymatically active paper sheet or filter cloth

Enzyme	Concentration of rate-limiting substrate	*p*H	Temperature (°C)
+ Lactate dehydrogenase	0 14 mM sodium pyruvate	7 4	25°
■ β-Galactosidase	2 5 mM *o*-nitrophenyl-galactoside	7 2	25°
□ β-Galactosidase	4 mM lactose	7 2	40°
▲ Pyruvate kinase*	0 26 mM ADP	7 4	25°

○ Chymotrypsin	1 per cent (w/v) casein	8 5	22°

* Two sheets
† Attached to filter cloth

operated On an industrial scale, filter cloths with enzyme action can be mounted in a plate-and-frame filter press, in the laboratory scale, small pieces of active paper can be used by mounting them in a filter holder (Gelman Instrument Co , Michigan) In this way, good flow rates can be obtained without plugging or channelling, and the bed size can readily be altered by adding or removing sheets By using several sheets with different enzymes attached, it is possible to build a "multi-enzyme" reactor

De-esterification using Ion Exchangers

Ion exchangers, as the name implies, are used principally for the removal of unwanted ions. but they have also been used for ionic catalysis. In particular, cation exchangers in the H^+ form have been employed to catalyse reactions requiring H^+ in which the product is required free from acid

The hydrolysis of esters can be catalysed by acids or bases, but the latter are more effective Esters of different types of alcohol (primary, secondary, hemiacetal) have different stability to base-catalysed hydrolysis This property was employed in the selective hydrolysis of peracetylated sugars with acetonic potassium hydroxide to give compounds which are esterified at the primary hydroxyl groups only[1-3] The sugar products of these reactions were accompanied by potassium acetate from which they had to be separated

This communication describes the use of anion exchange columns to accomplish two tasks first, to catalyse the hydrolysis of esters and, second, to absorb the acid so formed Peracetylated sugars and sugar alcohols were used as starting materials Preliminary experiments indicated that weak anion exchangers such as 'Dowex 3' or 'Duolite *A*6' were not effective and so 'Dowex 1' was used A column of this material effectively hydrolyses β-glucose pentacetate or β-galactose pentacetate to the free sugar, or sorbitol hexacetate to the alditol at room temperature If, however, the temperature is below 5° C, then the deacetylation is not completed Thus 'Dowex 1' × 1 50–100 mesh (400 g) was equilibrated with normal sodium hydroxide, washed three times with water and twice with actone water 1 1 and placed in a cooled Liebig condenser measuring 200 × 2 cm and washed with acetone–water until the *p*H of the eluant was below 8 Ten grams of β-glucose pentacetate or β-galactose pentacetate in 20 ml acetone was then applied to the column, which was maintained below 5° C The column was eluted with acetone–water The first 650 ml of eluate contained the products, which were a mixture of several acetates of the sugars, with 6-*O*-acetyl glucose or 6-*O*-acetyl galactose, respectively, predominating These were crystallized and identified When sorbitol hexacetate was applied, thin layer chromatography of the eluate (silica-gel *D*5 from Camag developed with chloroform methanol, 88 12, and made visible with iodine), showed the product to be a mixture of acetates Of these, the 1,6-di-*O*-acetyl sorbitol predominated Also present were monoacetyl sorbitol, esterified at a primary alcoholic group, and triacetyl sorbitol (esterified at C1, C6 and C2 or possibly C5) and some tetraacetyl sorbitol

At both room temperature and in the cold, the column absorbed the acetate that was formed Attempts to use the column for a third task, namely, that of separating the sugar–ester products from each other, were unsuccessful

Preliminary experiments indicate that the method of ion exchange de-esterification would be widely applied, not only for sugar esters but also for lipids Thus glyceryl tripropionate was hydrolysed to a mixture of glycerol and monoglycerate A paper chromatogram of the latter reacted slowly with alkaline permanganate–periodate spray[4] (for glycols), and weakly with the alternate periodate–*p*-anisidine spray[5] but strongly with alkaline hydroxylamine–acidic ferric chloride spray[6] (for esters) Quantitative periodate oxidation confirmed that it was a mixture of α- and β-monopropionin The mixture could have arisen as a result of acyl migration[7]

Polyacetylated oligosaccharides can also be deacetylated in this fashion, for the 'Dowex 1' column does not affect most glycosidic linkages Even the relatively labile β-fructofuranoside linkage is not hydrolysed, and, on deacetylation, sucrose octacetate gave sucrose admixed with sucrose monoacetate On the other hand, in suitable conditions, 'Dowex 50' and other cation exchangers hydrolysed glycoside bonds but not acetyl bonds

RADIOBIOLOGY

Attenuation in the Chest Wall of 20 keV X-rays from an Inhaled Radioactive Aerosol

External counting of the low intensity *L* uranium X-rays (energies 13 6, 16 9 and 20 2 keV) is a promising technique for the estimation of insoluble compounds of plutonium in the human lung These low energy radiations are, however, very easily absorbed in the tissues of the chest wall, the half-value thickness (HVT) is about 0 7 cm of soft tissue and only 0 03 cm of bone The effects of variations in body build are clearly important and difficult to assess, and calibration of the counting equipment is a severe problem One approach has been the use of a phantom[1] or cadaver[2] In neither of these cases is there any certainty that the radiation from plutonium inserted into the chest cavity will undergo the same attenuation by surrounding tissues as *in vivo*

There are now techniques for the preparation of monodisperse aerosols of polystyrene particles, labelled with radio-nuclides, and suitable for inhalation by volunteers[3]. This has made it possible to study the plutonium calibration problem *in vivo*, using radio-nuclides which decay by orbital electron capture, and so emit characteristic X-rays. As the first radio-nuclide for investigation we chose 17 day palladium-103, which emits the characteristic K X-rays of rhodium (K_α at 20·2 keV, K_β at 22·8 keV) and is thus very suitable as a component of "mock plutonium"[4].

Irradiated palladium was purified and converted into the bis-diethyldithiocarbamate, which was dissolved in xylene containing 0·2 per cent of polystyrene. Because the palladium-103 emits no significant gamma-radiation we used 27·9 day chromium-51 to provide a "label" (0·323 MeV gamma-rays). This was added to the polystyrene solution as the acetylacetonate, to give a mixture of approximately equal activities at the beginning of the experiments. A monodisperse aerosol of polystyrene particles 5 μm in diameter was generated by the spinning disk technique[3].

Seven healthy adult men volunteered to inhale the radioactive aerosol; the weights and heights of the subjects covered a wide range as shown in Table 1. The lung contents of chromium-51 were determined by gamma-ray spectrometry using two collimated crystals of NaI(Tl), 15 cm diameter by 8·9 cm thick, placed above and below the chest of the supine subject as described elsewhere[3]. From the estimated contents of chromium-51 (Table 1) the contents of palladium-103 were calculated from the known initial activity ratio and the half-lives.

The X-rays from the palladium-103 were measured inside a lead shield with a gas-flow (90 per cent Ar, 10 per cent CH_4) proportional counter, approximately 30 cm square, placed about 1 cm above the highest point of the chest of the supine subject. This counter, which will be described in detail elsewhere, uses the multi-wire method of internal anti-coincidence for background reduction[5]. The main counting volume of 9 l. is defined on four sides by 103 wires which also form the cathodes for thirty-nine anti-coincidence counters; these reduce the background response from about 725 c.p.m. to 13 c.p.m. above a threshold of 8 keV. A further reduction to 4 c.p.m. results from the use of pulse rise time discrimination[6], which also reduces the contribution at low energies from the chromium-51 gamma-rays, but without affecting significantly the response to 20 keV X-rays. For these experiments, an energy band of 14–29 keV was used and the background in this band was 2·3 c.p.m.

The counting rate per microcurie of palladium-103 was determined at various times after the inhalation, and in Fig. 1 the results are plotted as a function of the ratio of weight to height (a measure of the average cross-section area of the body) for the seven subjects. Two sets of results are shown—those obtained from the first measurement after inhalation and the average of those obtained after 48 h and up to 14 days, when the early phase of elimination from the lung was complete. At 48 h the average retention was 69 per cent (range 62–76 per cent), and in all subjects the retention was decreasing only slowly.

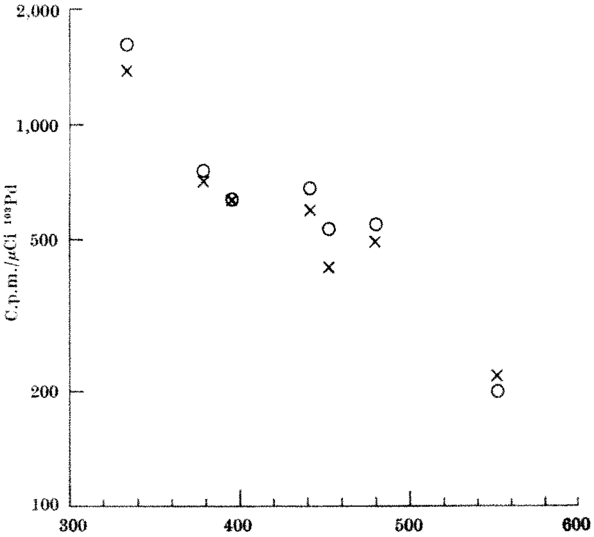

Fig. 1. Variation of counting efficiency with the ratio weight/height. ○, Measurements at about 30 min after inhalation; ×, average of measurements made between 2 days and 14 days after inhalation.

Table 1

Subject	Age	Weight (kg)	Height (cm)	Chest circumference (cm)	Radioactivity inhaled, μCi ^{51}Cr	Radioactivity inhaled, μCi ^{103}Pd
D.V.B.	46	61·5	184	88·6	0·304	0·226
D.N.	30	64·5	170	93·5	0·098	0·081
R.P.R.	40	70·5	178	95	0·278	0·172
J.E.M.J.	56	79·5	180	96·3	0·260	0·171
J.R.	42	80·6	178	99·7	0·367	0·273
N.G.S.	51	88·0	183	105	0·311	0·205
J.W.C.J.	47	107·0	194	114	0·315	0·195

There is a remarkable degree of correlation between the counting efficiency and the crude measure of body thickness represented by the ratio of weight to height. A very similar correlation was observed when the results were plotted against the chest circumference. There was only a small change in the counting efficiency as a result of the removal of some 30 per cent of the activity, presumably from the ciliated region of the lung. There was no significant systematic change after 2 days; when we ignore effects of statistical fluctuations, the range of all the values for any one subject corresponds to a change in average absorption of only 5 mm of soft tissue (about half one HVT at 20·2 keV).

The factor of eight between the efficiencies for the subjects at the extremes of build corresponds to a difference in absorption of about 3 cm of soft tissue, and this is in very good agreement with the results of investigations using ultrasonics for subjects of similar builds[7]. In that method, however, only the soft tissue thickness external to the rib cage was measured, whereas our measurements give results which include the effects of the ribs, and of differences in the size of the lungs which affect the geometrical efficiency.

Because the uranium L X-rays emitted by plutonium-239 have energies between 13·6 and 20·2 keV, the variations in absorption of that radiation among subjects will be even bigger than observed by us. It should also be pointed out that the fraction of counts attributable to K_β radiation (22·8 keV) from palladium-103 in the lung is higher than that from a bare source, so that this method probably under-estimates the effects of absorption at 20·2 keV. We propose to carry out further experiments using other radio-nuclides which emit X-rays of lower energies and with more efficient counters being developed commercially from our design.

Influence of Micro-organisms on the Distribution in Roots of Phosphate labelled with Phosphorus-32

MICRO-ORGANISMS have been shown to affect profoundly the uptake of phosphate by plant roots, especially from dilute solutions[1-6]. The way in which they influence the distribution of phosphate between different tissues of roots has now been examined in autoradiographs.

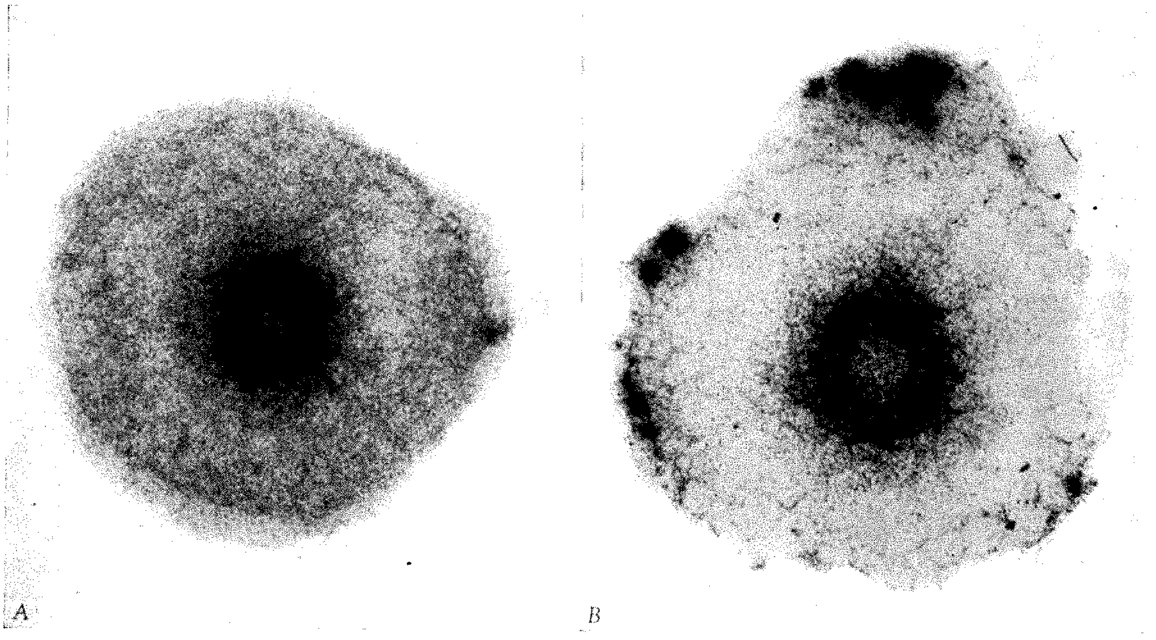

Fig. 1. Autoradiographs showing the distribution of phosphate in transverse sections of roots from barley plants which had been supplied for 6 h with 3×10^{-6} molar potassium phosphate containing 1 mc. of phosphorus-32/l. *A*, Plant grown in the absence of micro-organisms; *B*, plant infected at the ambient laboratory level.

Fig. 1 shows typical results for transverse sections of roots of 3 week old barley plants which were grown under sterile and non-sterile conditions and which were supplied for 6 h with 3×10^{-6} molar solutions of potassium phosphate containing 1 mc. of phosphorus-32. The procedures for plant culture have been described by Barber[4]; autoradiographs were prepared by the method of Crossett[7].

In roots which were grown in sterile conditions, phosphate was distributed relatively uniformly throughout the cortex and there was a marked accumulation in the stele. The presence of micro-organisms, however, led to considerable concentration of phosphate in irregular zones close to the root surface. These are attributed to the accumulation of the ion in colonies of bacteria, for microscopic examination showed that there was no fungal invasion of the cortex. This accumulation of phosphate in micro-organisms is readily compatible with the observation that nucleic acids account for a considerably larger fraction of the recently absorbed phosphate in infected than in uninfected roots[2,3,5].

The extent of microbial infection in the root (Fig. 1*B*) is likely to be less than the infection which frequently occurs in water culture because, in order to ensure comparability between sterile and non-sterile plants, all the seedlings were initially grown in sterile conditions, infection being brought about by aeration with unfiltered air. Autoradiographs in which the peripheral accumulation of phosphorus-32 was continuous have been prepared by Crossett[7] from the roots of maize plants which had been grown from germination without any attempt to exclude micro-organisms; he suggested that concentration of the ion in bacteria might be responsible.

It is thus evident that unless plants are grown under rigidly sterile conditions the observed distribution of phosphate between the root cortex and other tissues cannot be regarded as resulting solely from the metabolism of the plant. The extent to which the distribution of other ions is influenced by micro-organisms is not known, but a number of investigations have shown patterns of accumulation which are compatible with the view that microbial effects could be at least a contributory factor; for example, highly localized sites of accumulation of caesium in young barley roots[8] and the concentration of iron in the superficial tissues of pea roots[9].

MICROBIOLOGY

Stimulative Vaporization of Phenylmercuric Acetate by Mercury-resistant Bacteria

PHENYLMERCURIC acetate (PMA) has been widely used as a fungicide and as a disinfectant. It is well known that the antibacterial action of mercuric compounds results chiefly from their interference with essential

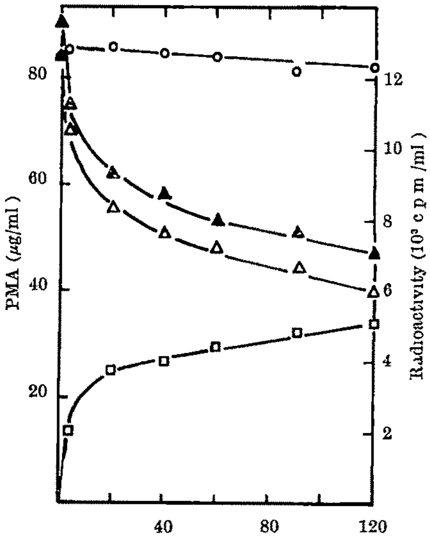

Fig 1 Uptake of ^{203}Hg-PMA by mercury-resistant bacteria The washed cells of the organism (8 8 × 10^8) were incubated in 1 ml cf 0 02 M phosphate buffer, *p*H 7 2, containing 90 p p m PMA Radioactivity in the whole medium (○), supernatant fluids (△), and cells (□) was assayed PMA in supernatant fluids (▲) was also assayed colorimetrically

sulphydryl groups of organisms There are, however, reports that some micro-organisms are resistant to mercuric compounds Russell[1] showed that a mercury-resistant strain of *Penicillium roqueforti* Thom was able to absorb a large amount of mercury from nutrient media containing PMA Stutzenberger and Bennett[2] have shown that *Staphylococcus aureus* is more resistant to mercuric compounds in the presence of *Escherichia coli* which produces extracellular glutathione and hydrogen sulphide This communication describes an experiment in which a large amount of PMA was absorbed by mercury-resistant bacteria The PMA was located chiefly on the bacterial surface and it was biologically stimulated to cause vaporization there

The mercury-resistant micro-organism was isolated from soil by enrichment culture containing glucose, mineral salts, vitamins and PMA The soil from which the micro-organism was isolated was heavily contaminated with PMA The micro-organism produced water-insoluble red pigment and possessed general characteristics of the genus *Pseudomonas* The growth of the organism was inhibited at concentrations of 450 p p m in mercuric chloride, 120 p p m in PMA and 20 p p m in ethylmercuric phosphate These concentrations were about a thousand times greater than those of other bacteria like *Escherichia coli* and *Pseudomonas aeruginosa*

The organism was grown in medium containing glucose, mineral salts and vitamins on a shaker When the washed cells of the organism were incubated in 0 02 M phosphate buffer, *p*H 7 2, containing PMA labelled with mercury-203, PMA was taken up by the organism (Fig 1) PMA was assayed by the colour formed from reaction with dithizone in chloroform[3] Radioactivity in the cells, supernatant fluids and the whole medium was assayed with a scintillation counter The PMA-bound organism was disrupted by Braun's cell homogenizer with beads for 5 min so that the intracellular distribution could be studied, and then it was differentially fractionated by centrifugation Results obtained showed that 76 per cent of radioactivity was present in the pellet obtained after centrifuging at 2,000*g* for 15 min, although 12 per cent of protein was present in this fraction (Table 1) Bound PMA could be easily extracted with 0 1 M acetic acid A mercuric compound extracted from the cell was compared with standard PMA by thin-layer chromatography—no difference could be found between them

Table 1 DISTRIBUTION OF ^{203}Hg-PMA TAKEN UP BY MERCURY-RESISTANT BACTERIA*

Fraction	Radioactivity 10³ c p m	%	Protein mg	%
Homogenate	384	100	45 0	100
2,000*g*, 15 min, pellet 1	264	76	5 2	12
14,000*g*, 15 min, pellet 2	34	10	6 8	15
37,000*g*, 15 min, pellet 3	49	14	7 7	17
100,000*g*, 60 min, pellet 4	15	4	1 6	4
Supernatant 4	6	2	23 0	51

* The organism was disrupted after incubation for 2 h in the same conditions as in Fig 1

Table 2 ABSORPTION OF VAPORIZED RADIOACTIVE MERCURY BY ACTIVE CARBON

Organism	Added PMA		Radioactivity Medium		Carbon	
	c p m /ml	%	c p m /ml	%	c p m /ml	%
Not added	4,220	100	4,054	96	129	3
Added	4,220	100	1,527	36	2,800	67

To find the fate of cell-bound PMA, the PMA-bound organism was transferred to a fresh culture medium containing glucose, mineral salts and vitamins The composition of this medium was as follows 2 5 g of glucose, 0 2 g of KH_2PO_4, 1 6 g of K_2HPO_4, 1 g of $(NH_4)_2SO_4$, 0 2 g of $MgSO_4$ $7H_2O$, 0 02 g of $CaCl_2$ $2H_2O$, 0 1 g of NaCl, 0 01 g of $FeSO_4$ $7H_2O$, 0 5 mg of Na_2MoO_4, 0 5 mg of Na_2WO_4, 0 5 mg of $MnSO_4$, 400 μg of Ca-pantothenate, 200 μg of *p*-aminobenzoic acid, 400 μg of pyridoxine hydrochloride, 400 μg of thiamine hydrochloride, 400 μg of riboflavine, 2 μg of biotin, 0 5 μg of vitamin B_{12}, 1 l of distilled water, *p*H 7 2

It was found that cell-bound radioactivity disappeared rather rapidly from the culture before the beginning of growth (Fig 2) The *p*H of the culture medium changed only from 7 2 to 6 7 during this 53 h of incubation Free PMA, however, hardly disappeared from the solution in the same conditions When the organism was incubated directly with radioactive PMA in culture medium, the disappearance of radioactivity from the culture was also observed A modified type of Conway's microdiffusion apparatus[4] was used to trace this vaporized radioactive mercury It consisted of a glass container resembling a Petri dish (83 mm in inner diameter and 26 mm deep), within which was placed a smaller dish (50 mm in diameter and 13 mm deep) 1 g of active carbon was introduced into an inner dish In an outer dish which was tightly sealed, the organism was incubated in 10 ml of culture medium with 15 p p m PMA for 24 h at 25° C The result showed that the vaporized radioactivity was completely recovered by carbon (Table 2) It is obvious therefore that PMA was bound to the bacterial surface and then it was biologically stimulated to cause the vaporization of mercury The vaporization, however

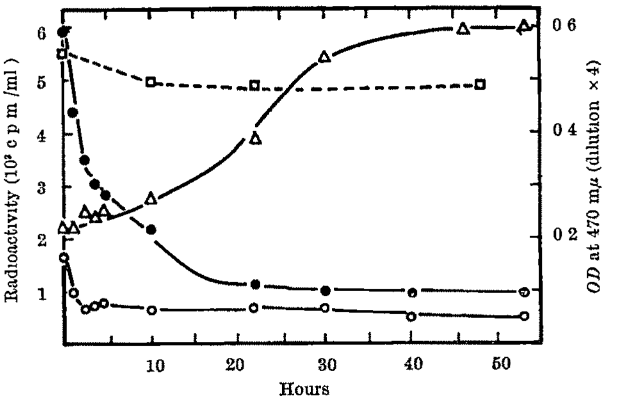

Fig 2 Vaporization of cell-bound ^{203}Hg-PMA PMA-bound cells were transferred to fresh culture medium and incubated Free PMA was also incubated in the same conditions as described here Radioactivity in the whole medium (●) and supernatant fluids (○) and in free PMA solution (□) was assayed The specific activity was 232 c p m per μg of PMA Growth (△) was measured by reading the optical density at 470 mμ

was not stimulated by heated cells, by cells treated with acetone or toluene, nor by disrupted cells The vaporization was inhibited at concentrations of PMA higher than 150 p p m and it was enhanced by cells pre-incubated with PMA The mechanism of the vaporization is not clear, but there are two possibilities The first is that the vaporization is stimulated by a gaseous substance evolved from the bacterial surface on which PMA is bound The second possibility is that there is a chemical conversion of PMA to a substance which is more volatile than PMA Evidence was obtained which suggested that the vaporized mercuric compound was different from PMA This idea was suggested when the vaporized compound absorbed to ferric hydroxide was examined by thin-layer chromatography after extraction with ethylacetate in the presence of hydrochloric acid This, however, does not preclude the first possibility It seems to be interesting that the environment contaminated with PMA is purified by the organism capable of removing PMA from its environment This then results in the proliferation of the organisms

Action of Hydroxyurea on Multiplication of Influenza Virus in Mammalian Cells

HYDROXYUREA has been reported to be a specific inhibitor of DNA synthesis *in vitro* and *in vivo*[1,2] Inhibition results from interference with the reduction of ribonucleotides to deoxyribonucleotides[1,3,4] Hydroxyurea has also been shown to inhibit the multiplication of vaccinia virus[5] and T_4 bacteriophage[6] There has been some controversy concerning the part played by the host cell genome in the multiplication of the influenza virus[7,8] Hydroxyurea was used in this study to gain insight into this question

In 1961 Wong and Kilbourne[9] described a clone of a morphological variant of Chang's conjunctival cell which supported the complete growth of influenza virus These cells (clone 1-5c-4), grown in 60 × 15 mm Petri dishes[10], were used throughout our investigations Influenza *A/NWS* adapted to this cell line was provided by Dr E D Kilbourne The virus was propagated in embryonated eggs and stored at −70° C In all experiments, the input multiplicity was 8–10 PFU/cell and the monolayers were maintained under Eagle's medium containing two times vitamins, amino-acids, glutamine and 0 1 per cent bovine serum albumin fraction V After infection the cultures were incubated at 37° C in a humidified atmosphere containing 5 per cent carbon dioxide for 24 h The supernatant fluids were then removed, cleared by low speed centrifugation and titrated for haemagglutinating activity, using serial two-fold dilutions, and infectivity using half-log dilutions in embryonated eggs Hydroxyurea was found to inhibit the haemagglutinin production of virus infected cultures This effect was observed in cultures that were frozen and thawed (total virus) as well as those in which only the supernatant fractions (extra-cellular virus) were analysed

Table 1 EFFECT OF VARIOUS CONCENTRATIONS OF HYDROXYUREA ON THE HAEMAGGLUTINATION AND INFECTIVITY TITRES OF INFLUENZA *A/NWS* GROWN IN 1–5*c*–4 CELLS

Concentration of hydroxyurea (molar)	Haemagglutination* titre	Infectivity EID_{50}/ml †
10^{-2}	1 4	$10^{-7\ 13}$
10^{-3}	1 4	$10^{-7\ 13}$
10^{-4}	1 8	$10^{-7\ 25}$
10^{-5}	1 32	$10^{-7\ 25}$
10^{-6}	1 64	$10^{-7\ 38}$
Control	1 64	$10^{-7\ 25}$

* Two-fold dilutions using 0 5 per cent fowl red blood cells
† Negative logarithm to the base ten

The optimal concentrations of hydroxyurea producing this effect were 10^{-2} and 10^{-3} M as shown in Table 1 Both concentrations seemed to be equally effective in reducing the haemagglutinin yield, without an appreciable effect on the infectivity titre of the virus produced in this tissue culture system Higher concentrations of hydroxyurea were toxic to the cells during the experimental period, and lower concentrations did not produce an optimal effect When a sample of a standard preparation of virus was incubated with 10^{-2} M hydroxyurea for 1 h at 37° C and a similar sample without hydroxyurea was titrated, the haemagglutinating activity and infectivity titres were the same.

Fig 1 shows that the pretreatment of the cell culture for 1 h was essential for the inhibition of haemagglutinating activity, longer pretreatment periods did not alter the effect If hydroxyurea was added with the virus or any time after infection, a gradual decrease in the inhibition of haemagglutinating activity production was observed until 4 h post-infection when there was no inhibition of either the haemagglutinin or infectivity yields

The inhibitory action of hydroxyurea on DNA synthesis in this system was investigated by determining the rate of incorporation of ^{3}H-thymidine into acid insoluble material in treated and untreated cell cultures The reduction of ^{3}H-thymidine into hydroxyurea treated cultures was 85–95 per cent of the control cultures This inhibition indicates that DNA synthesis, as measured in this manner, was effectively inhibited by 10^{-2} and 10^{-3} molar hydroxyurea

The results already described and those reported for the action of cytosine arabinoside[11] suggest that DNA synthesis in the host cell is not a necessary condition for the replication of influenza virus Although studies with actinomycin *D* have shown that actinomycin *D* does interfere with influenza RNA synthesis[12], they cannot

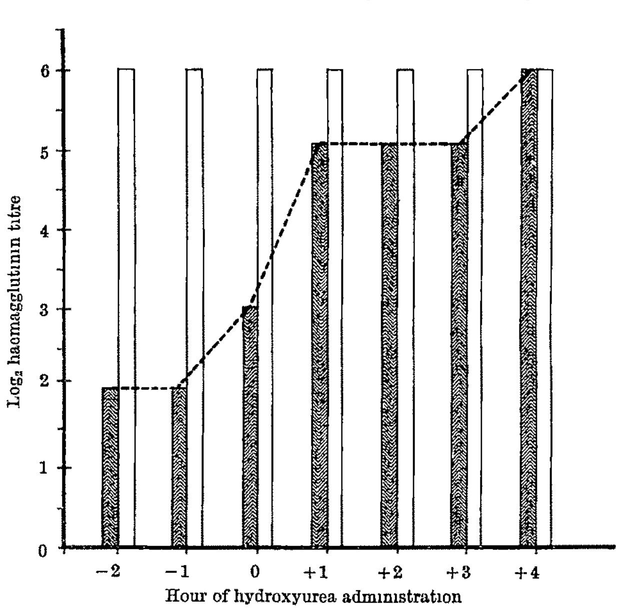

Fig 1 Temporal sequence of inhibition of influenza virus haemagglutinins by hydroxyurea White columns, control, shaded columns, treated

rule out the possibility that host cell genome function may be essential[7,13] This participation of the host cell in influenza replication may perhaps be reflected by the action of hydroxyurea on the production of functional viral haemagglutinin Further efforts at determining the effects of hydroxyurea on the multiplication of influenza virus in the conjunctival cell system are in progress

Cercariae of *Schistosoma mansoni* and Plants: Attempt to penetrate *Phaseolus vulgaris* and *Hedychium coronarium* produces a Cercaricide

DURING the development of a method for evaluating the penetration of the cercariae of *Schistosoma mansoni*[1], a large percentage of the larvae were observed to penetrate the skin of dead as well as living mice. In addition, many cercariae attacked isolated mouse tissue, as had previously been reported[2] Furthermore, similar numbers of cercariae entered the skin of a wide variety of rodents regardless of whether or not the animals were hosts within which the larvae could complete their life cycle[3] It is well known that avian schistosomes penetrate mammalian skin where they die, in man this results in a severe dermatitis known as "swimmer's itch"[4] Thus these organisms seem to be bereft of any discriminatory mechanism in their attack on mammalian tissues In the plant kingdom, cercariae were observed to attempt to penetrate the integument of the green string bean, *Phaseolus vulgaris*, lose their tails in the process and thereby immobilize themselves Investigation of eighty-one aquatic plants failed to reveal a similar penetration phenomenon, but resulted in the discovery of a cercaricidal substance which exuded from the cut stem of the white butterfly lily, *Hedychium coronarium*

The method for evaluating the penetration of schistosome cercariae can be summarized as follows Using a bacteriologist's loop, forty cercariae were placed in non-wetting polystyrene containers After exposure of various materials to the cercariae, the contents of the container were poured into a Petri dish, and the intact cercariae, cercarial heads and tails were counted The number of intact cercariae and heads subtracted from the number of cercariae originally added provided the number of penetrants, the number of intact cercariae and tails provided a check on the cercariae placed in the containers In several hundred individual experiments the original count was verified in more than 90 per cent, and in the remaining 10 per cent it deviated by one or, rarely, two cercariae As well as using this technique, the behaviour of the larvae on contact with the various materials was observed under a dissecting microscope After exposure to large numbers of cercariae, samples of the plant material were preserved in buffered formalin for later sectioning and staining with haematoxylin and eosin

When the tails of anaesthetized living Swiss albino female mice were exposed to forty cercariae of a Puerto Rican strain of *S mansoni* in 5 ml of dechlorinated water for 30 min, penetration approached 90 per cent (Table 1), a high degree of penetration in similar conditions was also observed when the mice had been killed by cervical dislocation 3 days earlier, maintained at −30° C and warmed to room temperature before exposure (Table 1) In addition, the washed, isolated small intestine of freshly killed mice was also invaded by large numbers of cercariae (Table 1) A similar degree of penetration, as indicated by the disappearance of cercarial heads from solution, was observed when the green string bean, *Phaseolus vulgaris*, was exposed in the same conditions (Table 1)

Table 1 PENETRATION OF FORTY *S mansoni* CERCARIAE INTO LIVING AND DEAD ANIMAL AND VEGETABLE MATERIAL DURING A 30 MIN EXPOSURE IN 5 ML OF WATER

Material	No of specimens	Per cent penetration
Tails of living mice	40	87 5 ± 0 70
Tails of dead mice*	10	76 5 ± 2 18
Isolated mouse small intestine	10	61 3 ± 2 36
Green string bean, *Phaseolus vulgaris*	10	67 0 ± 2 32

* Dead 3 days (maintained in freezer), experiment performed at room temperature

Further studies, using the dissecting microscope, revealed that when the cercariae came into contact with the green string bean, they went through the series of penetrating motions described by Stirewalt and Hackey[2] and in the process they lost their tails Stained sections of the beans revealed cercariae in the process of penetration, but no cercariae were observed beyond the superficial outer layers of the vegetable (Fig 1)

In contrast, exposure of ten specimens each of two other vegetables, celery and scallions, and three aquatic plants, *Pomatogeton*, *Myriophyllum* and *Eichornia*, resulted in no penetration, nor did *S mansoni* cercariae attack specimens of seventy-eight other species of aquatic or semi-aquatic plants which were similarly tested *H coronarium*, however, had a profound effect on the cercariae When the stem of this plant was cut off just above the crown (the usual procedure for studying plants with root systems) and inserted into the plastic cup containing forty cercariae in 100 ml of water, the cercariae were attracted to the stem, the tails broke off, and it

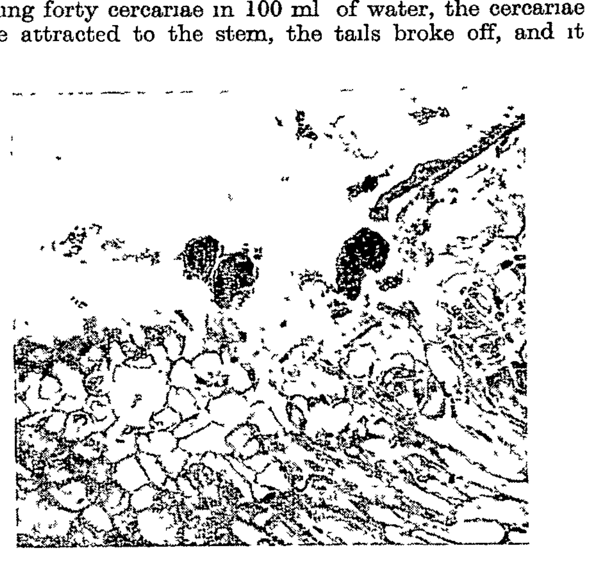

Fig 1 Cercariae of *S mansoni* attempting to penetrate the integument of the green string bean, *Phaseolus vulgaris* Stained with haematoxylin and eosin (×200)

seemed at first as though the heads were disappearing from the solution When a lily stem and the tail of a living anaesthetized mouse were placed at opposite ends of a container, the separated cercarial tails were divided equally between them Further study, however, revealed a situation which was completely different from that which had occurred with the string bean When the intact butterfly lily, complete with root system, was exposed to cercariae, the larvae did not attempt to penetrate the stem of the plant Within a few minutes, however, after cut pieces of stem were added to the water, the cercariae began to break apart, fell to the bottom of the cup and rapidly ceased all movement Even after the solid material had been removed by filtration, the solution remained toxic to the parasite larvae In contrast, when the cut ends of the stems were sealed with silicon stopcock grease, no cercaricidal effect was observed

The plant kingdom has been associated with schistosomiasis in several respects, for (*a*) plants are important in the ecology of snails, (*b*) the fruit of several plants are reported to show molluscicidal activity, and (*c*) various plants are widely used by practitioners of Chinese traditional medicine in the treatment of schistosomiasis and its complications[5] Our investigations reveal further associations between plants and schistosomes which have implications in relation to the distribution and control of the disease

This investigation was supported in part by US Public Health Service grants and by a Rockefeller Foundation grant

Filtration of Arboviruses through 'Millipore' Membranes

CURRENT attempts[1,2] to fit the arboviruses within a universal system of classification have revealed severe deficiencies in the knowledge of the basic physical structural and biochemical properties of these agents, on which proposed systems are chiefly based

Although virus size is not among the properties used for classification in one of the proposed schemes[3], it nevertheless seems logically connected with at least one element used in that scheme, for markedly dissimilar sizes within a collection of viruses may reflect differences in number of capsomeres as well as in the triangulation numbers of agents with cubic or icosahedral symmetry In addition, heterogeneity in size may correspond with heterogeneity in still other properties

The present observations regarding the behaviour of arboviruses on filtration through 'Millipore' membranes were made as part of a continuing investigation in this laboratory Properties other than size may affect the filterability of viruses through such membranes, and the commercially available membranes represent only a limited range of average pore diameter (APD), and so these observations are at best estimates of virus size within rather wide limits rather than accurate size determinations

The technique usually employed was similar in some respects to that used with simian viruses[4] Except for group *C* agents, each virus preparation was made up as a 10^{-2} suspension of infected newborn mouse brain tissue, using an electrical blender, with group *C* viruses (Nos 13, 14 and 15 in Table 1), a similar dilution of infected serum or whole blood was employed The diluent was 0 02 M phosphate buffer in physiological saline, *p*H 7 2, to which was added 0 75 per cent bovine plasma albumin (Armour fraction V) Between 50 and 60 ml of the freshly prepared virus suspension was spun in a Spinco preparatory centrifuge (Model *L*, Type 40 rotor) at 15,000 r p m for 30 min or, in the case of some of the larger viruses (Nyamanini, herpes, Newcastle disease), at 5,000 r p m for 30 min The supernatant fluid was then filtered by pressure (20 p s i) successively through filters of APD 450, 220, 100 and 50 mμ, the diameter of each filter was 47 mm and a microglass prefilter was used in all cases At each stage about 5 ml was reserved for infectivity titration The least volume emerging through the last filter was 10 to 15 ml The original crude suspension, the supernatant fluid and each successive filtrate were titrated by the intracerebral route of inoculation in 2–4 day old mice, eight mice being used for each dilution

* Based on the APD of the two consecutive filters between which dex 1 5 or more of virus was removed

† Expressed in dex/0 02 ml

‡ N indicates no virus recovered

With a few exceptions, the size of the viruses tested was such that they were neither sedimented by the centrifugation employed nor excluded by the filter of APD 450 mμ to a significant degree In nearly all instances, the infective titre of material passing the 450 APD membrane was not more than 0 7–1 0 dex[5] lower than the titre of the original suspension, and this loss was caused as much by centrifugation as by filtration For our purposes, therefore, the 450 APD filtrate has been adopted as the working suspension, and reduction of infective titres resulting from subsequent filtrations has been calculated with reference to it rather than to the crude original 10^{-2} brain suspension

Several viruses not arboviruses (Nos 27, 28 and 29 in Table 1) were included because their sizes have been reported[6–8], usually as determined by electron microscopy, similarly, for some of the arboviruses included there are reports of measurements, by the same and other techniques[9] It was presupposed that the observed degree of filterability of viruses of known size in the present system would permit certain inferences, by analogy, about the relative size of the other arboviruses

The results presented in Table 1 show, not unexpectedly, that the viruses tested differed considerably in degree of filterability, and presumably therefore in relative size, in our experimental conditions Considering a loss of 1 5 dex or more in infective titre as significant, viruses Nos 1–5, represented by group *B* agents and one from group *A* (chikungunya), were not affected by final filtration through the smallest APD used, 50 mμ Viruses Nos 6–9, however, suffered a loss of titre on filtration through the 50 mμ APD membrane, particularly pronounced in the case of *WEE* and Bunyamwera and less so for Sindbis and *EEE* Kemerovo virus (No 11) has been reported[10] to have a virion size, including its envelope, of between 60 and 100 mμ, and its behaviour on filtration corresponds well with this size The behaviour of reovirus type 3 (No. 27) on filtration similarly corresponded with its reported size of 70–77 mμ

The greatest number of viruses (Nos 12–25) experienced a significant loss of infectivity on filtration through the 100 mμ APD membrane but either no loss or only a moderate loss on filtration through a 220 mμ membrane These viruses comprised members of group *C* (Nos 13, 14 and 15), Bwamba (No 12) and tick-borne viruses not of group *B* (Nos 16–25)

Nyamanini virus (No 26) has repeatedly shown considerable loss of titre on filtration through a 220 mμ APD membrane, if particle aggregation can eventually be ruled out, this loss in titre may indicate an unusually large size of arbovirus

These observations seem to provide further evidence that the group of the animal viruses carried by arthropods is heterogeneous in physical properties, inclusion of the arboviruses in a universal scheme will have to acknowledge such heterogeneity

CYTOLOGY

Gene Amplification in the Oocyte Nucleus of Mutant and Wild-type *Xenopus laevis*

During the development of the amphibian oocyte, the germinal vesicle becomes enlarged and can be seen to contain very many nucleoli[1,2] instead of the four which would be expected from the tetraploidy of the egg nucleus The RNA of these nucleoli is similar in base composition to ribosomal RNA[3] and each nucleolus contains a small amount of DNA[4–6] Amphibian oocyte nucleoli can be hypotonically disrupted to reveal DNP rings in the shape of beaded circles or necklaces[2,6] There is compelling evidence in amphibia[2,6,7] as well as in the insect *Tipula*[8] that this DNA is derived from the chromosomal nucleolar organizer region which contains the ribosomal cistrons[9,10] This conclusion is supported by the recent finding that in ovarian tissue of *Xenopus* there is a disproportionately greater synthesis of ribosomal cistrons[11] which leads eventually to a higher proportion of them than that found in DNA of somatic tissues[11,12] In *Bufo*, the nucleolar DNA migrates as granules from the chromosomal bouquet to the periphery of the nucleus where, at later stages, the granules give rise to nucleoli[5] A similar process occurs in *Xenopus* where Feulgen-positive material appears in the oocyte nucleus as a "nuclear cap" at leptotene[13] After zygotene this cap disperses and numerous nucleoli are formed which contain one or several DNA cores or rings[14]

Table 1 OCCURRENCE OF NUCLEOLI, NUCLEOLAR CORES AND NUCLEOLAR DNA IN THE OOCYTES OF MUTANT AND WILD-TYPE *Xenopus laevis*

Cores				
0 3 –1 4	10	36	5,265 ± 145	5,120 ± 125

Oocytes were removed from ovaries of seven wild-type and five heterozygous adult females in 0 1 M potassium chloride 0 1 M sodium chloride (5 1) The germinal vesicles were isolated manually, under a binocular microscope, washed several times in the same medium by repeated gentle syringing in a Pasteur pipette and, when free of all yolk, transferred into a well which contained 0 2 per cent $(NH_4)_2SO_4$ together with a trace of methylene blue The well consisted of a perforated microscope slide to which a coverslip had been fastened with paraffin–wax mixture The nuclear membrane was disrupted by means of two tungsten needles and the well covered with another coverslip to the exclusion of all air The slides were then kept for at least 24 h in the cold to allow settling out of the nucleoli The nucleoli were counted in a Wild inverted microscope fitted with a drawing tubus. In some experiments, in order to reveal the nucleolar cores, the isolated germinal vesicles were disaggregated in 0 02–0 05 per cent $(NH_4)_2SO_4$

We have counted nucleoli and nucleolar cores in *Xenopus laevis* and have found that the *Xenopus* oocyte nucleus contains some 1,400–1,600 nucleoli and some 5,200 nucleolar cores (Table 1) The nucleolar count remains constant for a range of oocyte diameters (0 4–1 0 mm) Contrary to our expectations, the number of nucleoli and the abundance of the nucleolar cores are unchanged in the mutant form of *Xenopus* in which one of the two chromosomal nucleolar organizers is deleted[15,16]

From the microspectrometric quantitation of the Feulgen stain in oocyte nuclei at post-zygotene—a time in development when all incorporation of ^{3}H-thymidine into the nucleus has ceased[13]—we deduce that mutant and wild-type nuclei both contain a similar amount of DNA (Table 2) This amount has been found to be about 42 pg for the wild-type oocyte[13] From this value we subtract 4C (12 pg (ref 9)) DNA in order to obtain a mass for the amplified DNA of 30 pg

Two molecular mechanisms have been suggested for the production of the extrachromosomal nucleolar DNA units[6] (*a*) the chromosomal organizer is the only template and (*b*) the product of endoduplication can serve as further template in this process The results with the mutant *Xenopus* do not exclude possibility (*a*) We now know, however, that in *Xenopus* the number of chromosomal organizers is in itself not a limiting factor in the production of these extra copies The controlling factors for amplification must obviously lie elsewhere The concept of a cascade effect in gene amplification (possibility (*b*)) is strongly favoured by the finding that the rate of incorporation of ^{3}H-thymidine is roughly proportional to the mass of the DNA already amplified[13] According to this scheme, the mutant nucleus could easily achieve the same degree of multiplicity by a single additional round of reduplication (twelve rounds rather than eleven)

In somatic tissues the ribosomal cistrons represent some 0 2 per cent of the genome, or some 0 1 per cent organ-

Measurements were obtained from five preparations Each preparation was made from a different pair of animals

Female *Xenopus* weighing between 0 4 and 1 g were used as a source of material for all photometric observations In each preparation an ovary from a wild-type animal was squashed, before hydrolysis and staining, on the same slide as an ovary from a mutant sib The two ovaries therefore underwent precisely the same hydrolysis, staining, washing, dehydration and mounting procedures Feulgen dye contents were measured in post-zygotene nuclei in which the cap of nucleolar DNA had more or less dispersed Details of the technique are described elsewhere[13]

izer[9,16] If gene amplification in the oocyte were concerned with the replication of the entire block of ribosomal cistrons, the 5,200 cores would be expected to represent 520 per cent of the diploid DNA mass The *Xenopus* nucleus contains some 6 pg of DNA[9], so 5,200 such DNA units would yield some 31 2 pg of DNA This is remarkably close to the amount determined in the spectrophotometric experiments We take this to mean that amplification in the oocyte is concerned with the entire cluster of ribosomal cistrons, and thus with the nucleolar organizer as a whole, resulting in an increase in the number of ribosomal cistrons per cell from 1,600 in somatic tissues to some 4×10^6 in the oocyte

It is easily demonstrated that an increase of this magnitude in the number of ribosomal cistrons is highly advantageous for the oocyte The mature *Xenopus* oocyte contains some $1\ 1 \times 10^{12}$ ribosomal 28*S* and 18*S* RNA molecules (4 µg (ref 17)), the somatic cell, on average, some $3\ 3 \times 10^6$ (12 pg (unpublished results of M L B)) In rapidly proliferating tissue with a generation time of 24 h, a complete set of ribosomes will be synthesized with every cell division, at a rate of the order of 1 4 ribosomes/cistron/min If ribosome synthesis occurred at this same rate in the oocyte, in the absence of gene amplification, some $1{\cdot}7 \times 10^5$ days would be necessary for the production of the oocyte ribosomal RNA Amplification of the genes by a factor of 2,600 would reduce the time interval to some 65 days, which is an interval commensurate with the time necessary for oocyte growth

Epidermal Cell Population Kinetics in Albino Guinea-pig Skin

IN adult mammals the epidermal cell population is in a steady state—continuous cell loss by keratinization is balanced quantitatively by new cell production in the basal layer. We have found that the turnover time of albino guinea-pig epidermis (time required for the replacement of a number of cells equal to that present in the basal, spinous and granular layers) differed from that reported by Platt[1] and also from that found for other mammals[2–5]

To determine the turnover time of the epidermis by the method of Leblond *et al* [6], we needed to know the DNA synthesizing time, t_s Because t_s of many mammalian cells was reported to be 6–8 h, several workers have assumed t_s to be 7 h when calculating the turnover time for the human epidermis[1], rat oesophageal epithelium[5] and human sebaceous glands[7] It should be pointed out, however, that t_s for a number of mammalian cells is shorter or longer than 6–8 h, for example, t_s for mouse ear epidermal cells is 30 h (ref 5) We therefore determined the t_s of guinea-pig epidermal cells using double labelling with ^{3}H and ^{14}C-thymidine Hair was clipped from the flank of albino guinea-pigs when about 4–6 months old and weighing 500–800 g Three hours after intradermal injection of 2 5 µCi of ^{3}H-thymidine (5 0 Ci/mmole) in 0 1 ml of saline, 2 5 µCi of ^{14}C-thymidine (37 9 mCi/mmole) in 0 1 ml of saline was injected into the same sites, and the animals were killed 1 h later at 4 00 to 5 00 p m Labelled thymidine was assumed to remain available to cells synthesizing DNA for less than 1 h (ref 8) Pieces of skin, about 1 cm in diameter, were fixed in 10 per cent formalin, embedded in paraffin, and cut to 6µ thick The slides were dipped in NTB-3 liquid emulsion, dried in a horizontal position, developed with Kodak *D*-19 developer after exposure for 21 days, and stained with haematoxylin (Fig 1). Tritium gave silver grains in one focal plane immediately over the cell nucleus whereas carbon-14 produced a spray of tracks of silver grains in many focal planes above and around the cell nucleus, and so the cells labelled with tritium alone and the cells labelled with carbon-14 alone or with both isotopes were clearly distinguishable from each other The difference between labelling with carbon-14 and with tritium was much clearer under the microscope when there was a film of water between emulsion and cover glass. Two-emulsion autoradiography was also carried out according to the method described by Baserga[9], but we found this method no better than autoradiography with only one emulsion

The time of DNA synthesis, t_s, was calculated by the following formula[10]

$$t_s = \frac{N^{14}{}_{\mathrm{C}}}{N^{3}{}_{\mathrm{H}}} \times t_a$$

where $N^{3}{}_{\mathrm{H}}$ indicates the number of cells labelled with tritium alone, $N^{14}{}_{\mathrm{C}}$ the number of cells labelled with carbon-14 alone or with tritium, and t_a the time interval between labelling, which was 3 h in this study.

Table 1

Animal	Average No of ^{14}C-labelled cells in a section ($N^{14}{}_{c}$)	Average No of ^{3}H-labelled cells in a section ($N^{3}{}_{H}$)	$N^{14}{}_{c}/N^{3}{}_{H}$	DNA synthesizing time in h (t_s)
1	81	29	2 8	8 4
2	73	23	3 2	9 6
3	77	23	3 4	10 2
4	76	25	3 0	9 0
				Mean 9 3

One or two skin sites were used for each animal and at least eight sections were counted for each skin site to obtain the average number of labelled cells

Table 1 shows that the average t_s from four animals was 9 3 h. The 4 h interval between the injection of tritiated thymidine and the killing of animals in our determination of t_s could be too long, for some of the cells labelled with tritium could complete mitosis during this interval We found, however, only a few cells labelled with tritium which entered mitosis in the 4 h interval, and no labelled cells seemed to be the progeny of initially labelled cells This observation was similar to the findings with human and pig epidermis[2–4] in which paired labelled cells were first noted 12–24 h after injection of ^{3}H-thymidine Thus, it is very likely that the postsynthetic period (G_2) in epidermal cells is unusually long as compared with that of other cells[11], and all the cells labelled with tritium which we counted were likely to have been labelled originally

In the next series of experiments, animals received an intradermal injection of ^{3}H-thymidine in a dose of 5 μCi (5 Ci/mmole) in 0 1 ml of saline at various times between 1 h and 12 days before they were killed Autoradiographs of skin were made as already described

In the tissues obtained 1 h after injection of ^{3}H-thymidine, most labelled cells were found in the basal layer although there were a few in the transitional layer The total number of cells and the number of labelled cells in the interfollicular epidermis of these 1 h specimens were counted, and the values are shown in Table 2

The turnover time was calculated by the following formula[5]

$$T = \frac{N}{n_s} \times t_s$$

where T indicates the turnover time, N/n_s the ratio of the number of total cells to that of labelled cells in the slides obtained 1 h after injection of ^{3}H-thymidine, and t_s is the time of DNA synthesis

The average turnover time of guinea-pig epidermis obtained from six animals was 8 5 days (Table 2) Although this was very close to the turnover time for hairless mouse epidermis, 9–10 days (ref 12), it was shorter than that of human epidermis, 14–17 7 days (ref 2), or rat and mouse epidermis, 19–34 days (ref 8) The difference in epidermal turnover time between guinea-pig epidermis and other mammals was also obvious in the autoradiographs of skin specimens obtained at various time intervals after injection of ^{3}H-thymidine We found that by 6 days after injection of ^{3}H-thymidine some labelled cells had already appeared in the granular layer, and by 12 days most of the heavily labelled cells were in the granular layer (Fig 2), whereas labelled cells are reported to appear first after 10–14 days in the granular layer of human epidermis[1] and after 14 days in pig epidermis[3] Thus it seems that, contrary to previous conclusions of others[1,11], the turnover time of similar organs in different species is not always the same

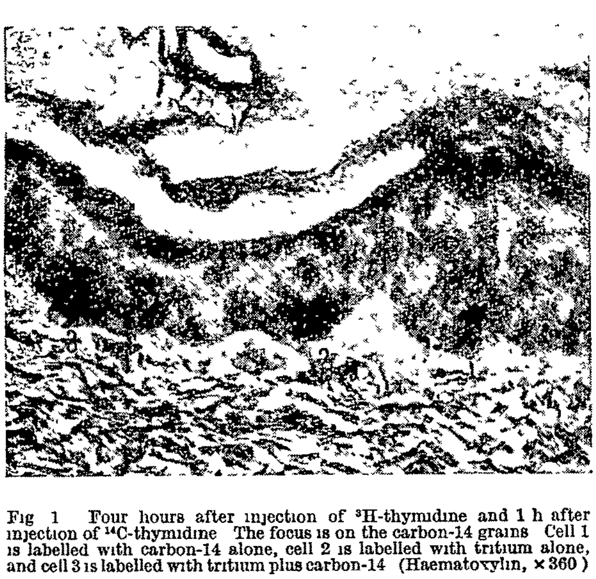

Fig 1 Four hours after injection of ^{3}H-thymidine and 1 h after injection of ^{14}C-thymidine The focus is on the carbon-14 grains Cell 1 is labelled with carbon-14 alone, cell 2 is labelled with tritium alone, and cell 3 is labelled with tritium plus carbon-14 (Haematoxylin, × 360)

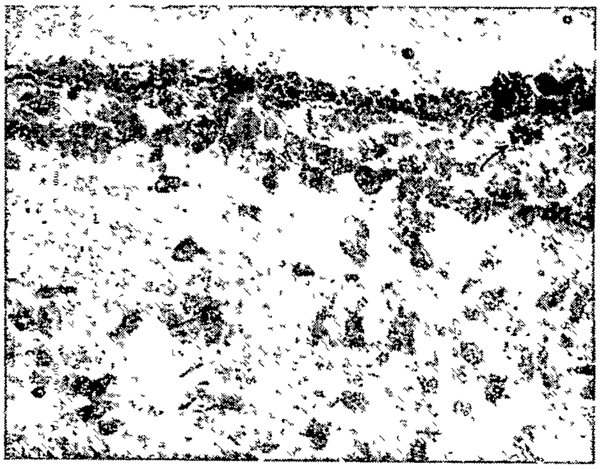

Fig 2 Twelve days after injection of ^{3}H-thymidine Heavily labelled cells are in the granular layer, and lightly labelled cells in the basal, spinous and granular layers are the progeny of the initially labelled cells (Haematoxylin, × 360)

Table 2

Animal	Average total No of cells in a section (N)	Average No of ^{3}H-labelled cells in a section (n_s)	N/n_s	Turnover time (h)	Turnover time (days)

Lens Soluble Proteins: Correlation with the Cytological Differentiation in the Young Adult Organ of the Chick

THE lens of the eye is an outstanding example of cellular differentiation. At any moment the organ shows the complete sequence of its cellular ontogeny from epithelial cells to equatorial, cortical and nuclear fibre cells[1,2].

The protein components of the whole lens have been extensively analysed during pre-natal and post-natal development. This research has made available more knowledge of the molecular structure of this organ.

The lens therefore appears to be an ideal model for analysing the correlation between structural and biochemical differentiation. Some data on the correlation between developmental differentiation of the lens and its protein biosynthesis have been reported[3]. Information on the structural and cytological organization of the lens, synthesis of structural proteins, *m*RNA stability, oxidative metabolism and patterns of lactic dehydrogenase isozyme activity has also been collected[2,4–7].

Most immunological studies on chicken lenses have been on pre-natal development in order to establish the sequence of appearance of structural lens antigens[8–13]. In the adult chick the data on the correlation between cytological and macromolecular differentiation are very limited. This investigation was carried out to look for a correlation between the differentiating cells of the lens and their proteins and structural antigens. We attempted to interrelate the immunological results with data provided by other techniques of protein analysis.

Lenses from 6 week old White Leghorn chickens were separately dissected in the following way. A tungsten needle was used to make a circular cut along the equator of the capsule. The anterior portion of the capsule was pulled off together with the epithelial cells. The equatorial region, which histologically corresponds to the annular pad, was removed joined to the rest of the capsule. Superficial cortical and nuclear fibre cells were isolated and the intermediate cells were discarded. The material collected therefore corresponds to the cytological differentiation sequence: epithelial cells corresponding to the epithelium, elongating equatorial cells to the annular pad zone, superficial fibre cells to the cortex and the deeper fibre elements corresponding to the nucleus. Lens tissues from the different regions of the organ were identified by phase contrast analysis (Fig. 1).

The material was pooled, weighed and homogenized in 0·85 per cent sodium chloride solution at 4° C, and centrifuged at 17,000*g* for 15 min at the same temperature. The protein content of the supernatants was evaluated according to Lowry *et al.*[14]. Extracts gave a protein concentration of 32 mg/ml for the annular pad cells, 42 mg/ml for the cortical fibre cells, and 78 mg/ml for the nuclear fibre cells. These concentrations refer to a 25 per cent dilution of the tissue wet weight. Thus the normal differences in protein content of annular pad cells (129 mg/g), cortical fibre cells (168 mg/g) and nuclear fibre cells (312 mg/g) were maintained in all the subsequent electrophoretic procedures. Because of technical difficulties epithelial cells were directly diluted and the protein concentration was adjusted to 30 mg/ml. Antisera to the complete adult chick lens were produced by subcutaneous injections of a mixture of chick lens extract, containing 50 mg/ml., and Freund's adjuvant into rabbits. A sample (5 ml.) of this suspension was separately injected and this was repeated at weekly intervals for a month. The antisera were collected from the rabbits 5 days after the last injection. Three electrophoretic techniques were used.

Agar immunoelectrophoresis was carried out in barbital buffer (0·1 molar, *p*H 8·6) in a field strength of 6 V/cm and starch gel electrophoresis was carried out in a *tris*-discontinuous system for 16 h at 12 V/cm according to Poulik[15]. Lens extracts (50λ) were electrophoresed in cellulose acetate medium using barbital buffer (0·1 molar, *p*H 8·6), using a Beckman Microzone electrophoresis cell for 30 min. Strips were scanned on a model *RB* Beckman 'Analytrol'.

Protein nomenclature used follows the recommendations of Zwaan and Ikeda[16]. According to these authors, the chick lens contains three chief groups of soluble proteins, alpha, beta and delta crystallins. Delta crystallin, found only in the Sauropsida, has often been considered as beta crystallin[11] and it has also been called FISC (first important soluble crystallin)[12].

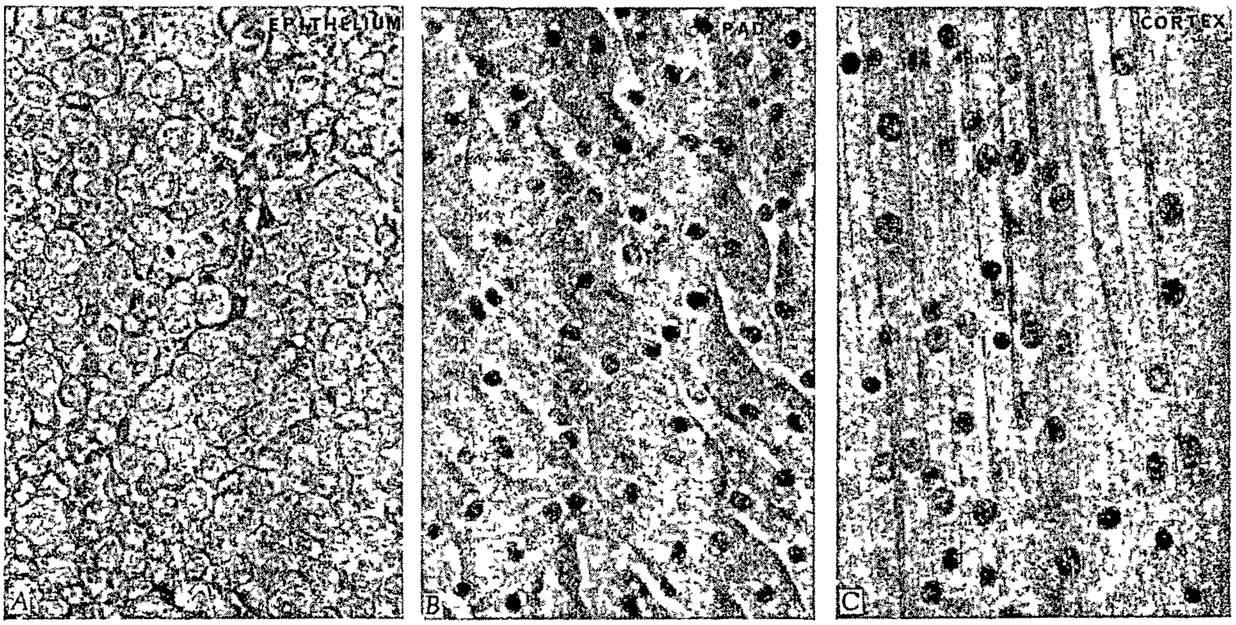

Fig. 1. Phase contrast analysis of lens tissues from different regions of lenses from 6 week old chicks (× 200). *A*, Epithelium; *B*, annular pad zone; *C*, cortex.

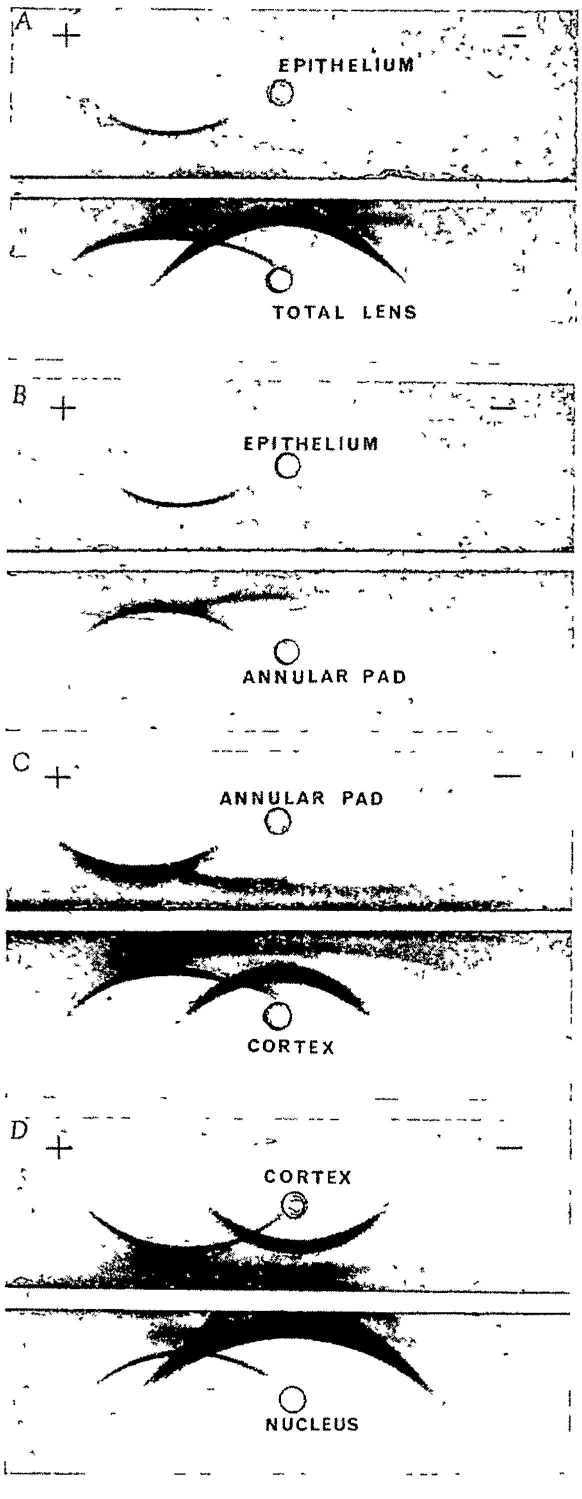

Fig 2 Immunoelectrophoretic patterns of extracts of total lens and differentiating lens parts *A*, Extracts of total lens and lens epithelium, *B* extracts of epithelial and equatorial cells, *C*, extracts of annular pad cells and cortex cells, *D*, extracts of lens cortex and nucleus

In this communication beta crystallin refers to all other protein families, irrespective of electrophoretic mobilities, with the exclusion of alpha and delta crystallin

The immunological pattern of extracts of total lens shows three principal precipitin reactions which correspond to the alpha, beta and delta groups of crystallins The precipitin arc for alpha shows the fastest mobility Beta antigenic determinants give rise to a long line which extends from the anode to the cathode Delta antigenic determinants delimit a sharply defined arc occupying an intermediate position A comparison between the patterns of total lens extracts and those detected in the differentiating lens parts clearly shows that antigenic determinants vary, both qualitatively and quantitatively, according to the cytological differentiation of the lens Thus the extracts of lens epithelium show two main precipitin areas with a mobility corresponding to the alpha and cathodal portion of the long line It also reveals that delta antigenic determinants are not present in the epithelial cells of the lens (Fig 2*A*)

The annular pad cells, which represent a more advanced degree of cytological differentiation and the beginning of cellular elongation, show two antigenic lines, which also correspond to alpha and beta crystallin determinants Differences between the precipitin patterns of the epithelial and equatorial cells are shown in Fig 2*B* The amount and mobility of alpha crystallin antigenic determinants are greater in the equatorial cells The intermediate portion of the long line is predominant in the annular pad cells Similar to the epithelial cells, the equatorial cells lack the reaction for delta crystallin, although a soft but faint antigenic arc with the mobility of delta crystallin was observed in some experiments

The simultaneous immunoelectrophoretic patterns of annular pad cells and superficial fibre cells show clearly that the elongated cells of the lens cortex have a marked reaction for delta crystallin The patterns also reveal a significant predominance of the anodic portion of the long line This is not present in either the epithelial or the equatorial cells The alpha antigenic determinants also have a higher mobility in the equatorial cells (Fig 2*C*) The innermost fibre cells of the lens nucleus show a pointed antigenic reaction for delta crystallin The antigenic determinants for alpha and beta crystallins are also present, but they are in low concentration (Fig 2*D*)

Similar results are obtained by subjecting the different lens extracts to starch gel electrophoresis (Fig 3) Thus band 3, which corresponds to alpha crystallin, is a predominant fraction at the epithelial, equatorial and cortical cells, although it can be detected in smaller quantities in the nuclear fibre cells There are differences in mobility between the alpha fractions of the pad and the other regions Band 4 was identified as delta crystallin This protein is significantly predominant in the nuclear fibre cells No traces of delta crystallin were found in the equatorial or in the epithelial cells Other bands which are present in the protein patterns of starch gel fractionation must be considered as beta crystallin (bands 1 2, 5, 6, 7) These protein fractions show different mobilities Thus bands 1 and 2 are in a cathodal position and predominant in epithelial and equatorial cells Band 5, with an intermediate mobility is mainly detected in

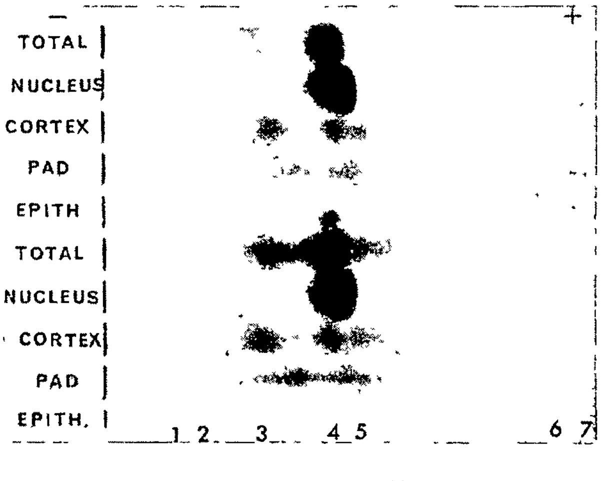

Fig 3 Starch gel electrophoresis of lens extracts

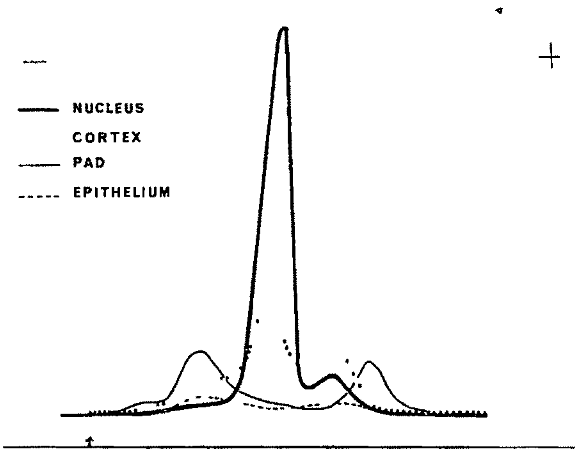

Fig 4 Cellulose acetate electrophoresis of lens extracts

the annular pad and cortical fibre cells Bands 6 and 7, with the fastest migration, can be registered in the cortical and nuclear fibres, but they were never detected in the eipthelial or equatorial cells

In cellulose acetate electrophoresis from the anode to the cathode, corresponding beta, delta and alpha crystallin were detected The nuclear fibre cells showed a marked concentration of delta crystallin (80 per cent) Alpha and beta crystallin were also detected but in low concentration (13 per cent and 7 per cent, respectively) Delta crystallin is still the predominant fraction (69 per cent) in the cortical fibre cells The concentration of alpha crystallin is clearly more than that of the beta fraction (47 per cent and 27 per cent, respectively) In the epithelial and annular pad cells two protein fractions were identified as alpha and beta crystallin, beta crystallin being in the higher concentration (66 3 per cent and 33 7 per cent) As it can clearly be seen, alpha crystallin molecules have a faster migration than alpha crystallin present in the nuclear or cortical fibre cells (Fig 4)

The analysis demonstrates that delta crystallin is mainly contained in the old central fibre cells and superficial cells of young animals, but it is no longer synthesized in the equatorial cells or in the epithelium Alpha crystallin seems to be produced in significant amounts in the epithelial, equatorial and cortical cells It is also present in low concentrations in the inner fibre cells Alpha crystallin is constantly more movable in the equatorial cells, suggesting physicochemical differences from the alpha crystallin of other differentiating lens cells Anodal beta crystallins are a typical characteristic of elongated lens fibres Medium migrating beta crystallins are a consistent feature of early cell differentiation at the equatorial region Cathodal beta crystallins seem to be synthesized in the young epithelial cells

The results, obtained by three different methods, are in general terms consistent They indicate clearly that antigenic determinants and protein patterns vary both qualitatively and quantitatively according to the sequence of differentiation and elongation of the lens cells

Plant Agglutinins and Mitosis

THE ability of saline extracts of certain plants to agglutinate human red cells was first noticed in 1888 (ref 1), and this property has since been found in many plants, particularly in the Leguminosae[2] Some plant agglutinins show blood group specificity[3–5]

Phytohaemagglutinin (PHA)—a plant agglutinin extracted from the red kidney bean, *Phaseolus vulgaris*—also agglutinates white cells[6,7] and stimulates lymphocytes to undergo mitosis when grown in tissue culture[8] Extracts of other leguminous plants[9] and of *Phytolacca americana*[10] also have mitogenic effects The nature of the relationship between the erythro-agglutinating, the leucoagglutinating and the mitogenic properties of plant agglutinins, however, is obscure

Attempts to fractionate the mitogenic and the agglutinating components of PHA have given variable results Punnett and Punnett[11], using fractional precipitation, were able to prepare a mitogenic fraction from PHA which was free from erythro-agglutinating activity, but, as they pointed out, it will not be certain that these two fractions are different components of PHA until a less drastic preparative procedure is developed Nordman *et al* [7], on the other hand, were unable to achieve separation of the erythro-agglutinating and leucocyte-mitogenic activities of PHA using ion exchange chromatography, gel filtration, starch gel and immunoelectrophoresis Similarly, Rigas and Johnson[12] prepared a purified protein fraction of PHA which had both agglutinating and mitogenic activities and which seemed to be homogenous after ultracentrifugation, a variety of electrophoretic and chromatographic techniques and N-terminal amino-acid analysis

Absorption experiments have also given differing results Elves and Israels[13] found that, when the erythro-agglutinating activity of PHA was reduced by absorption with red cells, the mitogenic effect was also diminished On the other hand, de la Chapelle *et al* [14] and Barkhan and Ballas[15] were able to remove most of the erythro-agglutinating activity from PHA by absorption with red cells and yet the mitogenic activity was unimpaired Nordman *et al.*[7], however, were unable to isolate erythro-agglutinins from PHA which lacked mitogenic activity, and they suggested that PHA contains a pure leuco-agglutinin and an erythro-agglutinin which also agglutinates leucocytes, and that both of these agglutinins are mitogenic

In an investigation of the properties of *Phytolacca americana*, Borjeson *et al* [16] were unable to separate chemically the agglutinating and mitogenic activities of the extract, although electrophoretic and chromatographic results indicated that the mitogen from *Phytolacca americana* has different mobility and charge properties from the mitogen of PHA In absorption studies of the extract of *Phytolacca* the haemagglutinin could be selectively removed with red cells or stroma without altering the

mitogen, whereas absorption with leucocytes resulted in loss of both mitogenic and leuco-agglutinating activity

In the present study, the erythro-agglutinating, the leuco-agglutinating and the mitogenic activities of several plant agglutinins, including blood group specific ones, have been compared in an attempt to ascertain the relationship between these different properties

The extracts which were prepared are shown in Table 1. Approximately 400 mg of the plant material was crushed in 7 ml of 0 9 per cent saline, left overnight at 4° C, centrifuged and filtered through a sterile bacteriological filter (porosity 5) The extract of *Dolichos biflorus* was specific for A_1 cells, and that of *Ulex europaeus* was specific for *H* substance, but the other preparations were non-specific Serial saline dilutions were made up to 1 in 800, and were tested against cells from healthy donors Erythro-agglutination was examined by the standard tube method and leuco-agglutination by the method of Killman[17], positive and negative controls were included in each experiment In the agglutination tests four doubling dilutions of the samples were also examined to a titre of 1/16 The erythro-agglutination was assessed macroscopically and graded + to 4+ The leuco-agglutination was read microscopically and graded + to 4+ Most of the samples which gave a positive result did so to a titre of 1/16 The leucocyte cultures were prepared by the method of Hungerford, Donnelly, Nowell and Beck[18], except that PHA was not added in the isolation of the leucocytes A sample (0 1 ml) of the plant agglutinin extracts was added to 2 ml of the leucocyte suspension which contained about $1\ 5 \times 10^6$ leucocytes/ml , and had a serum concentration of 20 per cent A negative control and a positive control with PHA (Difco *M*) were included in each experiment The cells from each culture were treated with a hypotonic citrate solution, fixed with acetic alcohol (one part glacial acetic acid, three parts methanol), spread on a slide and stained In the control and negative cultures, less than three mitoses were seen on the whole slide and when 1,000 cells were counted the percentage of mitoses was less than 0 1 per cent In the positive cultures many mitoses were seen in percentages which varied from 1–14 per cent and were graded + to 4+ The lymphocytes of at least three donors were tested with each extract The extracts of *Ulex europaeus* and *Dolichos biflorus* were tested against the lymphocytes of three donors of group *O* and three donors of group A_1 The results of the agglutination and cell culture tests were all read blind by two observers and were closely reproducible

The results are shown in Table 1 With one exception, all the extracts agglutinated white cells as well as red cells The extract of *Dolichos biflorus* agglutinated group A_1 leucocytes but not those belonging to group *O*, and the extracts of *Ulex europaeus* agglutinated leucocytes from group *O* subjects more strongly than those from group A_1 individuals Similar specific leucocyte agglutination by plant extracts has been described by Hossaini[19] Most of the extracts, including the blood group specific ones, failed to induce mitosis of lymphocytes, however

The present study shows therefore that, although plant agglutinins will commonly agglutinate leucocytes as well as red cells, they seldom also induce mitosis of lymphocytes in tissue culture This suggests that the mitogenic property present in some plant agglutinins is independent both of the erythro-agglutinating and leuco-agglutinating activity

Distribution of Some Dehydrogenase in the Cerebellar Cortex

Eccles and his colleagues have shown us that cerebellar cortical neurones are predominantly inhibitory elements, including those of Purkinje cells which inhibit the neurones of vestibular nuclei[1–4] The only excitatory elements known until now have been granular cells, and the individual structures and systems within the cerebellar cortex cannot be characterized according to their metabolic activity

We have tried to characterize histochemically the distribution of enzymes the functions of which are connected with glycolysis, the pentose shunt, the citric acid cycle, fatty acid oxidation and with a system which destroys gamma aminobutyric acid (GABA) Table 1 shows the methods which we used

Table 1

Enzymes detected	Incubation time (min)	Incubating medium, *p*H 7 2	Density of Purkinje cell/glomerulus / Geometrical thickness
Glucose-6-phosphate dehydrogenase	120	Substrate (0 1 M)	0 89
Isocitrate dehydrogenase	90	NADH/NADP 3 mM	0 95
Malate dehydrogenase	65	NBT/TNBT 0 025%	0 96
α-Glycerophosphate dehydrogenase	65	NaN_3 10 mM	0 65
β-Hydroxybutyrate dehydrogenase	65	$MgCl_2$ 7 mM	0 80
Lactate dehydrogenase	65	0 05 M *tris*-HCl buffer	1 11
Glutamate dehydrogenase	65	Cryostat sections	0 86
Succinate dehydrogenase	90	– 20° C	0 92
NADH-diaphorase	20	3 mM NADH	0 97
GABA-transaminase	90		1 03

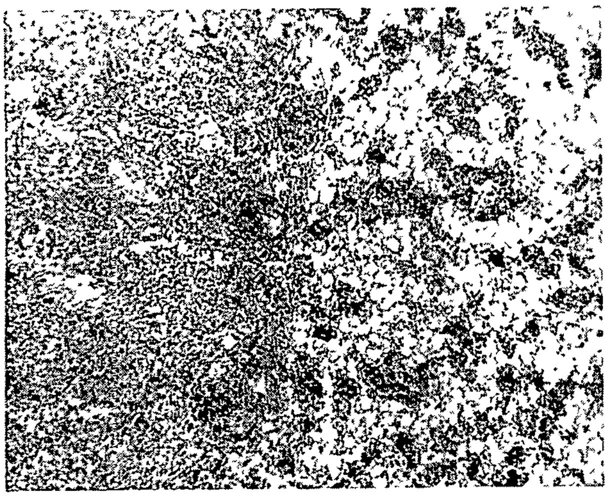

Fig. 1. Glucose 6-phosphate dehydrogenase (stained with TNBT, ×12.5).

Although the general patterns of distribution of the ten enzymes which we studied (in the rabbit cerebellar cortex) are all similar, there are some interesting differences. A high density of formazan deposits was found in the glomeruli of the granular layer as well as in Purkinje cells. The neuropil in the granular layer shows a diffused distribution of formazan deposits with a slightly lower density (Fig. 1). All enzyme reactions which we carried out were positive in Purkinje, stellate and basket cells and also in Golgi neurones. These results contradict the suggestion that succinate dehydrogenase is not active in small neurones of the molecular layer and in the Golgi cells[5]. Most important seems to be the question of whether there are any differences between the metabolic activity of excitatory and inhibitory neurones. While comparing slides which showed different histochemical reactions, we found that this question could be answered only qualitatively. All enzymes which we determined are present in the plasma of the granular cells. In cryostat sections, the cytoplasm of these cells fills a narrow space 0.3–0.5μ wide. The evidence of formazan deposits lies just on the resolution limits of the optical microscope and depends on results of the histochemical technique which is used. This is probably the reason why the ideas which have been published about enzyme activity in granular cells are so different[5–7]. In these cells, the degree of the enzyme activity which is detected histochemically probably depends on the dimensions of the cytoplasm and on its ultrastructural organization. We could find only six to ten mitochondria in the cytoplasm of an ultrathin section of a granular cell. Histochemical evidence methods indicate that there are no qualitative differences in dehydrogenase activity between excitatory and inhibitory neurones.

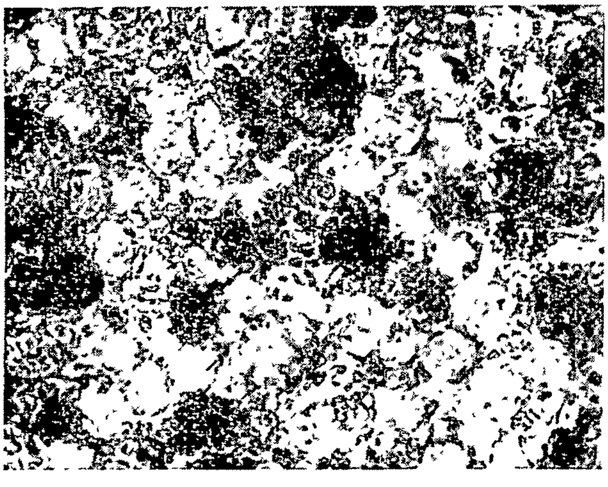

Fig. 2. GABA transaminase, according to Van Gelder (stained with TNBT, ×50). Formazan deposits seen in cytoplasm of granular cells.

The distribution of the enzyme which destroys GABA could be expected to be a reflexion of its function. The GABA transaminase succinic semi-aldehyde system has been assumed to exert its effect on inhibitory neurones postsynaptically, where GABA is destroyed in large quantities. This enzyme was also shown to be absent from granular cells[8–10]. We have used the same histochemical technique and been able to show evidence of significant activity of this enzyme in granular cells (Fig. 2). At least a part of this enzyme might be localized in the mitochondria. (The same picture was obtained with TNBT and NBT.) The enzyme shows remarkable activity in the glial cells of the white and grey matter (Fig. 3). This pattern of distribution of enzyme activity is very similar to that of other hydrogenases of the Krebs cycle.

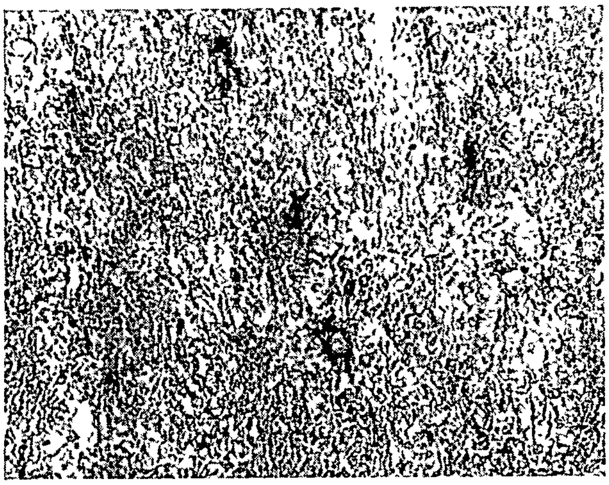

Fig. 3. Activity of GABA transaminase in glial cells of cerebellar white matter (×20).

Very high activity of dehydrogenases was observed in the spaces of the granular layer—the glomeruli cerebellosi. These glomeruli are structures where fibre terminals form a large presynaptic block which has contact with numerous granular cell dendrites and with dendrites of Golgi cells. Enzyme activity in these spaces seems to be an example of metabolic activity in a multisynaptic space. We tried to obtain more exact information about the activity of dehydrogenase in this space and in the cytoplasm of Purkinje cells, using a cytophotometer (wavelength 5600 Å) to compare the distribution of activity with the density of formazan deposits in these places. The extinction value divided by the measured geometrical thickness gives the degree of the density of formazan. Results are recorded in Table 1 and are expressed as the ratio of the density of Purkinje cells to that of glomeruli. The ratio of densities is very similar for the different dehydrogenases which are functionally connected with the citric acid cycle and NADH diaphorase. The activity of these enzymes is also very similar in Purkinje cells and glomeruli. (The ratio is near to 1.0.) Glutamate dehydrogenase, glucose-6-phosphate dehydrogenase and β-hydroxybutyrate dehydrogenase show higher activity in glomerular structure whereas GABA transaminase and chiefly lactate dehydrogenase show higher activity in the cytoplasm of Purkinje cells. The activity of α-glycerophosphate dehydrogenase in Purkinje cells is low, and this enzyme usually shows less activity in neurones and glial cells than in the neuropil

These results indicate that there are differences in the generally similar distribution pattern of different dehydrogenases Histochemical evidence is that glomerular structures show more activity of the dehydrogenases which we have investigated The relatively high activity of lactate dehydrogenase in the cytoplasm of neurones is interesting

IMMUNOLOGY

Passive Sensitization of *Salmonella adelaide* to the Bactericidal Action of Antibody and Complement

Red blood cells, onto which various unrelated antigens have been adsorbed or coupled chemically, may become sensitized to lysis by antibody against the adsorbed antigen in the presence of complement[1] In other words, lysis of red cells in this manner results from a heterologous antigen–antibody reaction with fixation of complement occurring on its surface The component requirements for cell damage by this system of antibody and complement seem to be identical irrespective of the nature of the cell involved, whether it is a red cell, a tissue cell or a Gram negative bacterium Passive sensitization to complement-induced lysis has been achieved using red cells coated with lipopolysaccharides or with bovine serum albumin (BSA)[2], with mast cells[3–5] and with lymphocytes[6,7] among others

We wished to know whether the similar behaviour of Gram negative bacteria as regards their killing and lysis by antibody and complement also extended to passive sensitization The plan was to couple various proteins to the surface of *S adelaide* through the agency of *bis*-diazotized benzidine in a manner analogous to that used by Rangel and Repka[2] with sheep red cells The sensitivity of the organisms to killing by the antibody–complement system was then determined by an assay similar to that described by Michael *et al*[8] Fresh guinea-pig serum was used as a source of complement and was absorbed for 60 min in an ice-water bath each day before use with approximately 10^9 living *S adelaide*/ml to remove any specific *S adelaide* antibodies After absorption the serum was sterilized by filtration through a 0 8 mμ 'Millipore' membrane Rabbit antisera against bovine serum albumin, mouse gamma globulin and aggregated human gamma globulin were all absorbed in this way to remove any naturally occurring anti-*S adelaide* antibodies The antibody contents of the various antisera were assayed by quantitative precipitation in the conventional manner[9]

Crystalline BSA was purchased from the Commonwealth Serum Laboratories, Australia, the mouse gamma globulin was prepared by fractionation on DEAE cellulose[10] of the serum globulins precipitated at 16 per cent sodium sulphate and the aggregated human gamma globulin by heating human gamma globulin (immune serum globulins from the Commonwealth Serum Laboratories) at 63° C for 20 min[11] Bacteria were coupled to proteins in the way described by Rangel and Repka[2] A volume (100 mg) of benzidine dihydrochloride was dissolved in 10 ml of 0 25 normal hydrochloric acid The solution was cooled to 0° C and 2 0 ml of precooled 0 5 normal sodium nitrite was slowly added with continuous stirring which continued while the solution was maintained at 5° C until no test for free nitrite was obtained with potassium iodide and starch This solution (*bis*-diazotized benzidine) was then diluted 1 30 with chilled 0 15 molar phosphate buffer, *p*H 7 4, and 5 ml was immediately added to 5 ml of a suspension in the same buffer of 10^8 *S adelaide*/ml which contained 10 mg of the protein to be coupled The suspension was stirred for 15 min at 4°–7° C, centrifuged once and the deposit diluted to a concentration of 2×10^4 bacteria/ml in 0 15 molar phosphate buffer, *p*H 7 4, containing 0 02 per cent magnesium chloride

After coupling in this manner, bacteria showed large and inexplicable variations in viability, in some instances only 1 per cent remained viable while in other experiments 90 per cent viability was obtained The only bactericidal assays considered to be satisfactory were those in which the original coupling reaction allowed more than 10 per cent of the organisms to survive

For the bactericidal assays, a suspension of 10^4 protein-coupled bacteria in 0 5 ml of a 1 10 dilution of absorbed guinea-pig serum was added to 0 5 ml dilutions of the appropriate antiserum at 4° C All dilutions were made in the 0 15 molar phosphate buffer, *p*H 7 4, containing 0 02 per cent magnesium chloride Plate counts of the numbers of bacteria/ml in each dilution were prepared at this time and again after 150 min at 37° C The number of colonies appearing after overnight incubation of the agar plates at 37° C was noted The magnitude of killing was assessed by comparison with dilutions of control coupled bacteria incubated for 150 min in the absence of antisera In order to establish that the killing of coupled bacteria in the presence of complement involved antibody directed specifically against the foreign protein, normal *S adelaide* was incubated as before with dilutions of the *S adelaide* absorbed rabbit anti-BSA

Fig 1 shows a typical relationship between the killing of both BSA-coupled and normal *S adelaide* as a function of the concentration of rabbit antiserum against BSA Although 50 per cent of the coupled bacteria were killed at a dilution of 1/5,000 the uncoupled bacteria required a dilution of 1/380 for the same degree of killing Coating the bacteria with BSA, however, did not impair the efficiency of killing by rabbit antiserum to *S adelaide* plus complement

The average results obtained from three separate experiments for each antiserum are shown in Table 1 Two findings emerged from these results first, that passive sensitization to complement-induced cytotoxicity occurs with Gram negative bacteria, and second, that the efficiency of killing by antibody plus complement seems to be related to the physical dimensions of the coupled foreign protein

The finding that bacteria, like other cells, can be killed by heterologous antigen–antibody reactions occurring on their surface in the presence of complement serves to emphasize the fundamental similarity by which these reactants act on all susceptible cells Moreover, it strongly

Table 1 BACTERICIDAL STUDIES WITH PROTEIN-COUPLED *S adelaide*

Foreign protein on *S adelaide* Nature	Molecular wt	Rabbit antibody used	Precipitable antibody protein (mg/ml)	Maximum dilution of antiserum producing 2 $\log_{10}$ kill	Conc of antibody (μg/ml at maximum dilution producing 2 $\log_{10}$ kill)
Uncoupled	—	Anti-*S adelaide*	0 26	1/10^7	2 6 × 10^{-5}
BSA	55,000	Anti-*S adelaide*	0 26	1/10^7	2 6 × 10^{-5}
		Anti-BSA	1 1	1/570	1 9
Mouse gamma globulin	160,000	Anti-mouse gamma globulin	4 8	1/270	18
Agg human gamma globulin	1–2 × 10^6	Anti-agg human gamma globulin	7 9	No kill	No kill

suggests that the appearance of holes in red cells or bacteria[12,13] after complement attack is not the result of a direct action on the antigen substrate but is a secondary effect consequent on the antigen–antibody fixation of complement as suggested by Muschel[15] The finding that the efficiency of killing seems to be related to the physical dimensions of the foreign protein is particularly apparent when one considers the concentration of specific antibody in μg/ml necessary to give a 2 $\log_{10}$ kill of the bacteria A 10^5-fold increase in micrograms of precipitable antibody/ml is necessary to kill *S adelaide* if the antibody is directed against the BSA coating rather than against the organism itself This is even more striking when the bacteria were coupled with mouse gamma globulin while coating with aggregated human gamma globulin failed to sensitize the organisms to killing by antibody plus complement

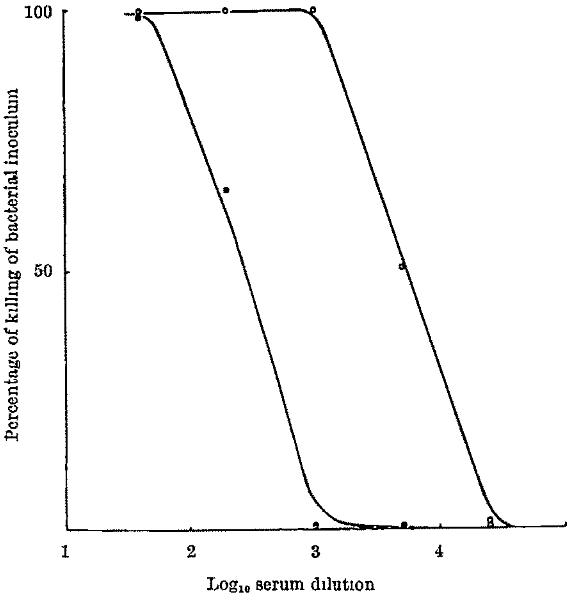

Fig 1 Bactericidal action of rabbit anti-bovine serum albumin serum (absorbed with *S adelaide*) against *S adelaide* (●) and *S adelaide* coupled to bovine serum albumin (○)

It seems unlikely that this great reduction in efficiency using antibody against coupled antigen could be explained by a paucity of antigenic sites In some of our experiments, BSA labelled with iodine-131 was used and this indicated that more than 10^6 molecules of BSA were coupled to each bacterial cell Moreover, with a strain of bacteria highly sensitive to antibody and complement it has been shown that the number of antibody molecules which need to react with the surface in order to kill the bacterial cell may be as low as thirty in the case of γM (ref 14)

These observations suggest that the efficiency of bactericidal effects which are mediated by complement is dependent on the effective distance at which complement is fixed from the bacterial surface Muschel[15] has offered a similar explanation for the fact that, while *P ballerup* is refractory to the bactericidal action of serum, spheroplasts of *P ballerup* are as sensitive to lysis, mediated by the antibody–complement system, as those of the moderately serum-sensitive *S typhosa* 0 901

In vitro Detection of Immunosuppressive Activity of Anti-lymphocyte Sera

THE problem of *in vitro* evaluation of anti-lymphocyte sera (ALS) has not yet been solved The tests used, such as leuco-agglutination, cytotoxicity and lymphocyte stimulation in culture, do not detect small amounts of anti-lymphocyte antibodies and, furthermore, the results of these tests are not regularly correlated with graft survival time[1,2] We propose a new *in vitro* test, based on inhibition of an active function of the lymphocytes

Immunologically active cells can be detected by an immunocyto-adherence technique—rosette formation[3,4] One rosette-forming cell (RFC) is found for every thousand lymphocytes in the spleen of Swiss and *C57Bl6* non-immunized mice incubated with sheep red blood cells (RBC) We have studied the *in vitro* action of ALS on this background of RFC

Ten heterologous anti-mouse ALS from rabbits (Table 1) were obtained as previously described[5] In four cases, immunization was achieved using rabbits which were previously tolerant to blood and kidney of mice[6] (ALS Nos 4, 7, 9, 10) These sera showed no activity or only weak activity against erythrocytes, serum and kidney of mice The technique of immunocyto-adherence was a modifica-

Table 1 INHIBITION TITRES OF TEN ALS

ALS	Antigen used for ALS production	Inhibition titre Without complement	With complement
1	Lymph node cells	1/600	1/10,000
2	,, ,, ,,	1/1,200	1/20,000
3	,, ,, ,,	1/1,200	1/20,000
4	,, ,, ,,	1/2,500	1/20,000
5	,, ,, ,,	1/600	1/1,200
6	,, ,, ,,	1/1,200	1/80,000
7	Homogenized lymph node cells	1/1,200	1/20,000
8	Insoluble fraction from homogenized lymph node cells	1/10,000	1/40,000
9	Thymic cells	1/2,500	1/20,000
10	Splenic cells	1/2,500	1/10,000

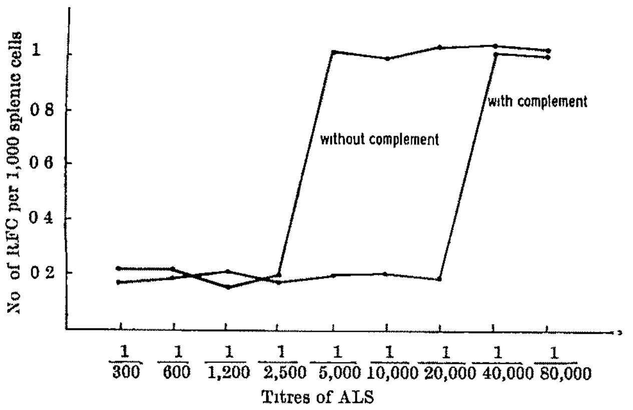

Fig 1 *In vitro* inhibition of rosette-forming cells with ALS ALS 4, leuco-agglutination titre, 1/16, cytotoxicity titre, 1/1,024, rosette inhibition titre without complement, 1/2,500, rosette inhibition titre with complement, 1/20,000

tion of Biozzi's method[7] 6 x 10[6] spleen cells were washed twice in Hanks BSS and were incubated for 90 min at 37° C, with two-fold dilutions of inactivated ALS After addition of 25 x 10[6] sheep RBC and centrifugation (200*g* for 5 min) the number of rosette-forming cells was counted in a haematocytometer

Results are shown in Fig 1 After incubation with ALS the number of RFC is 0 2/1,000 spleen cells as compared with the control value of 1 0/1,000 cells without ALS When ALS is diluted to 1/5,000, the number of RFC increases suddenly to 1/1,000 cells The test could not be performed with serum dilutions of under 1/300 because of leuco-agglutination Identical figures were obtained for all sera but one, the exception was serum 1 for which an intermediary plateau was observed over two dilutions From these experiments, the "inhibition titre" has been defined as the highest dilution for which the number of RFC is 0 3/1,000 cells or lower The inhibition titre was increased by complement (1/500 dilution of guinea-pig fresh serum) which was added before splenic cells were incubated with ALS For example, the inhibition titre of ALS 6 was 1/80,000 with complement as compared with 1/1,200 without complement Inactivated guinea-pig serum did not increase the inhibition titre

The mechanism of the inhibition of RFC by ALS is unknown The anti-sheep RBC antibodies contained in ALS are not concerned because the titre of rosette inhibition was not modified after absorption of these antibodies The anti-mouse immunoglobulin antibodies which are present in ALS do not seem responsible either, first, because anti-immunoglobulin sera inhibit the RFC[7] but not so strongly as ALS, second, because rosette formation is inhibited by ALS without any anti-immunoglobulin precipitating activity (ALS 2, 4, 6, 7, 9, 10), and third, because when complement is added the inhibition of RFC by anti-immunoglobulin sera is not increased Inhibition is not caused by cytotoxicity, as defined by the trypan blue exclusion test, because the titres for cytotoxicity are smaller than the inhibition titres

We are currently studying the possible correlation between this *in vitro* test and homograft survival Human application is feasible because inhibition of human lymphocytes with horse anti-human ALS has been found in preliminary experiments

BIOCHEMISTRY

Inhibition by Lasiocarpine of RNA Synthesis, RNA Polymerase and Induction of Tryptophan Pyrrolase Activity

Lasiocarpine a pyrrolizidine alkaloid derived from *Heliotropium lasiocarpium* or from *Heliotropium europaeum*, produces chronic liver damage and cancer in rats and other laboratory animals[1-3], and it induces nucleolar "capping"[4,5] (Fig 1) The functional significance of nucleolar "caps" is poorly understood They are probably related to alterations in DNA-directed RNA synthesis and RNA polymerase activity[6-8]

The studies of Christie[9] and Gallagher[10] deal with the effect of heliotrine and lasiocarpine on the activity *in vitro* of certain mitochondrial enzyme systems, but no information is available on the effect of pyrrolizidine alkaloids on RNA metabolism or on enzyme induction

During a comparative study of RNA synthesis after administration of selected hepatocarcinogens (unpublished work of J Reddy and D Svoboda), it was observed that lasiocarpine markedly inhibited the incorporation *in vivo* of ^{3}H-uridine into rat liver nuclear RNA and significantly lowered the RNA content of the nuclear and ribosomal fractions (Table 1) To elucidate further the mechanism of inhibition of ^{3}H-uridine incorporation by lasiocarpine and the significance of the concomitant morphological abnormalities in the nucleolus and cytoplasm, the effect of lasiocarpine or tryptophan pyrrolase induced by steroids and RNA polymerase activity was investigated

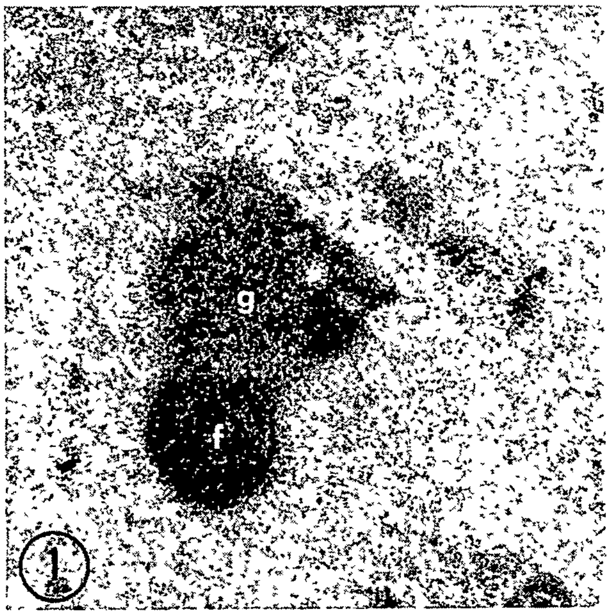

Fig 1 The nucleolus of a rat liver cell, 24 h after the injection of lasiocarpine, showing separation of the granular (*g*) and fibrillar (*f*) components to form two distinct zones (x 49,000)

With intraperitoneal injection (80 mg/kg body weight), lasiocarpine produced characteristic nuclear and cytoplasmic alterations in rat liver as early as 30 min after administration By 24 h, the nucleoli of almost all hepatic cells showed typical separation of the granular and fibrillar components (Fig. 1), which recovered by 72 h (ref 4)

For estimation of steroid-induced activity of tryptophan pyrrolase, adrenalectomized male *F*-344 rats weighing 200–300 g were injected with lasiocarpine (80 mg/kg body weight, intraperitoneally) and killed at 6, 24, 72 and 120 h Hydrocortisone acetate (2 5 mg/100 g body weight, intraperitoneal) was injected 4 h before death Tryptophan pyrrolase assays were performed according to the method of Knox and Mehler[11]

Table 1 EFFECT OF LASIOCARPINE ON LIVER NUCLEAR AND RIBOSOMAL RNA CONTENT, AND INCORPORATION *in vivo* OF ^{3}H-URIDINE

Group	RNA content*		^{3}H-uridine incorporation†	
	Nuclear RNA/DNA ratio (μg/μg)	Ribosomal RNA (mg/g liver)	Nuclear fraction (d p m / μg RNA)	Ribosomal fraction (d p m /100 μg RNA)
Control	0 196 ± 0 001 ‡	6 33 ± 0 06	2,166	1,230
Lasiocarpine 24 h (80 mg/kg body weight)	0 120 ± 0 006 (*P* > 0 001)	4 71 ± 0 08 (*P* > 0 001)	255	540

* Each group consists of five animals

† 24 h after the administration of lasiocarpine, two animals in each group were given 15 μCi of ^{3}H-uridine/g body weight intraperitoneally and killed after 30 min Results are expressed as average of two animals

‡ Mean ± standard error

The activity of RNA polymerase was determined on intact isolated nuclei[12] from livers of rats injected with a single dose of lasiocarpine at 2, 4, 6, 12, 24, 48 and 72 h before death Two rats were used for each interval Pure nuclear preparations were assayed in duplicate at each interval in the presence of 0·32 M ammonium sulphate, using the standard assay mixture for nuclear RNA polymerase based on the method of Gelboin *et al* [8] Nucleic acids were estimated by the method of Schneider[13] and the radioactivity was determined by using a Packard 'Tri-carb' liquid scintillation spectrometer

In the livers of adrenalectomized rats, lasiocarpine caused significant inhibition of steroid-induced tryptophan pyrrolase (Fig 2) at 6 h Even at 72 h after a single dose of lasiocarpine there was substantial reduction of tryptophan pyrrolase activity Recovery was apparent, however, at 5 days

The studies of *in vivo* incorporation of a 30 min ^{3}H-uridine pulse into rat liver nuclear RNA showed marked inhibition 24 h after lasiocarpine administration (Table 1)

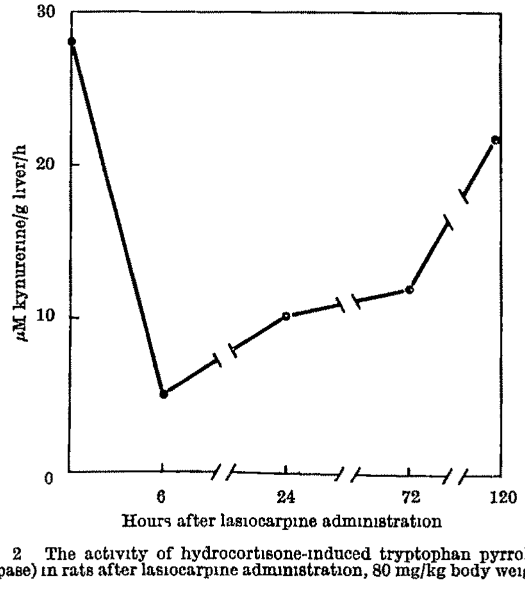

Fig 2 The activity of hydrocortisone-induced tryptophan pyrrolase (T-pase) in rats after lasiocarpine administration, 80 mg/kg body weight

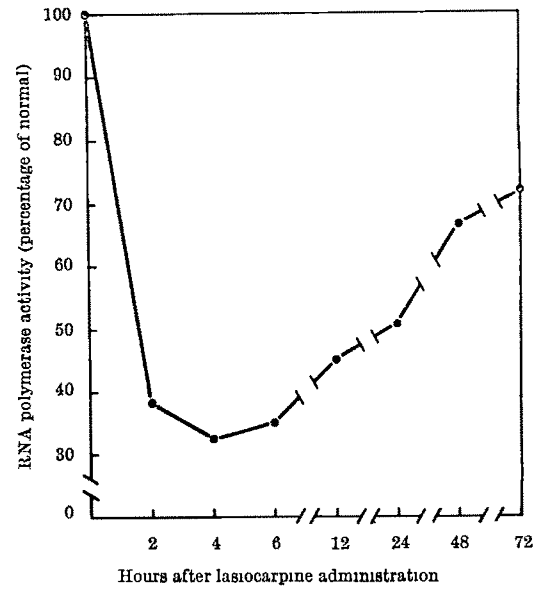

Fig 3 Rat liver RNA polymerase activity after lasiocarpine treatment The animals were injected with lasiocarpine 80 mg/kg body weight and killed at 2, 4, 6, 12, 24, 48 and 72 h

Likewise there was also a significant reduction in the labelled ribosomal RNA The depression of incorporation was accompanied by a 40 per cent reduction in the nuclear RNA/DNA ratio

RNA polymerase activity in the hepatic nuclei of rats treated with lasiocarpine for 2 and 4 h before they were killed was significantly decreased Fig 3 summarizes the data of incorporation of cytidine triphosphate into acid-insoluble material, in terms of percentage of normal Maximum inhibition (about 65 per cent) of RNA polymerase activity was still seen after 24 h, and nearly normal levels were noted by 72 h. Inhibition of RNA polymerase activity by lasiocarpine suggests that this agent, like aflatoxin B_1 (refs 8 and 14) and actinomycin *D* (ref 15), could interfere with transcription of the DNA molecule by inhibiting RNA polymerase activity. The analogy between lasiocarpine, aflatoxin B_1 and actinomycin is extended further by the similarity of the early morphological abnormalities in nucleoli caused by all three[4,16,17]

Because the nucleolus plays a significant part in the synthesis of ribosomal RNA, the derangements of RNA synthetic activity and the inhibition of tryptophan pyrrolase induction after lasiocarpine treatment may be related, in part, to the loss of structural integrity of the nucleolus The reversal to normal of the morphological changes 72 h after administration of lasiocarpine is accompanied by restoration of RNA polymerase activity Steroid induction of tryptophan pyrrolase has been shown to be dependent on intact systems for transcription and translation of protein synthesis[18,19], processes which are reflected in part by nucleolar and cytoplasmic morphology, respectively Significant restoration of tryptophan pyrrolase induction by hydrocortisone accompanies reversal to normal of the cytoplasmic changes 120 h after lasiocarpine This further supports the contention that aberrations in the nucleolar morphology reflect or occur concomitantly with biochemical lesions and decreased RNA polymerase activity related to transcription (DNA-dependent RNA synthesis)

Because the biochemical and ultrastructural effects of lasiocarpine on nuclei of rat liver cells are analogous to those of actinomycin *D* (refs 15, 16 and 19) and aflatoxin[8,14,17], it is suggested that inhibition of nuclear RNA synthesis, steroid induction of tryptophan pyrrolase and RNA polymerase activity are important biochemical defects in lasiocarpine injury and probably reflect the change termed nucleolar segregation or "capping"

These studies were supported in part by the US Public Health Service and by the Kansas Division of the American Cancer Society.

Urinary Peptides derived from the Cross-linked Regions of Connective Tissue Proteins

We have used 'Sephadex *G*-15' to examine the molecular weight distribution of urinary peptides obtained from normal males, aged between 22 and 24 yr, by a method designed to protect labile groups within peptides. We obtained a peptide fraction, of approximate molecular weight 600, which gave several slowly developing yellow Ehrlich positive zones after electrophoresis in pyridine acetate buffer at *p*H 5·5. This staining property was lost after chromatography in systems containing acetic acid, presumably because of oxidative decomposition on the paper surface in acetic acid. High voltage electrophoresis of this peptide fraction in pyridine acetate buffer at *p*H 3·7 showed that at least fifteen peptides were present.

Total hydrolysis of the whole peptide fraction in sealed tubes containing 6 N hydrochloric acid under nitrogen at 100° C for 24 h yielded a complex mixture of amino-acids. These amino-acids were separated with the Technicon autoanalyser system under nitrogen using the sodium buffer elution technique[1]. The hydrolysate contained the following. (*a*) Desmosine, isodesmosine and lysino-norleucine which are thought to be unique to insoluble elastin where they are known to be the acid stable cross-linkages[2,3]. (*b*) Hydroxyproline and hydroxylysine, the latter of which is known to be involved in glycosidic linkage with galactose and glucose in collagen[4] and has only been isolated from connective tissue proteins. (*c*) Two unidentified amino-acids, described as V* and Hi*, which have recently been observed for the first time in a protein fraction of the human intervertebral disk (unpublished results of F. S. Steven, D. S. Jackson and K. Broady). This protein is very firmly bound to collagen in the disk. The quantity of V* in the urinary peptide fraction is equivalent to 0·3 mg/l. of urine. (*d*) Several unidentified ninhydrin positive peaks which seem from their positions on the chromatographic elution pattern to be derived from basic amino-acids.

Table 1. R_F VALUES OF COMPOUNDS GIVING A YELLOW EHRLICH REACTION

Solvent	Iso-propanol : water 160 : 40	*n*-Butanol : ethanol : water 120 : 30 : 50	Colour development
Urea	62	41	Fast
Homocitrulline	27	17	Fast
Unknown	39	31	Slow

Total hydrolysis of the disk protein fractions referred to in (*c*) also yielded a yellow Ehrlich positive spot after two dimensional chromatography in systems which did not contain acetic acid. This yellow spot again failed to appear in hydrolysates which had been subjected to chromatography or electrophoresis in systems containing acetic acid. Table 1 shows the R_F values of urea, homocitrulline and the unknown Ehrlich positive spot.

Hydroxyproline peptides are commonly found in urine, but hydroxylysine has only once been observed[5] in normal adult urine. Desmosine, isodesmosine, lysino-norleucine and the unidentified amino-acids have not previously been reported in urine. The modified amino-acids have probably escaped detection in previous studies of urine, because little work has been carried out on these low molecular weight peptide fractions.

The presence of this peptide fraction suggests that the catabolism of connective tissue proteins proceeds normally by proteolytic digestion until a cross-linked region is reached. At this stage a fragment is released which contains the cross-link plus perhaps two amino-acid residues adjacent to the cross-link on each peptide chain. This fragment might be an enzyme-resistant H-peptide. The urinary peptides containing desmosine, isodesmosine or lysino-norleucine as cross-linkages would be derived from catabolism of elastin. Those peptides containing hydroxylysine would probably be derived from collagen catabolism and those peptides containing V* and Hi* might be expected to be derived from the disk type protein complex with collagen.

We thank Professors J. H. Kellgren and D. S. Jackson for their encouragement and support of this project.

Sedimentation Behaviour of Rapidly Labelled RNA from *Escherichia coli*

Rapidity of labelling after exposure to radioactive precursor is one of the distinctive characteristics of bacterial messenger RNA (*m*RNA)[1]. In early studies, rapidly labelled RNA prepared from bacterial extracts obtained by alumina grinding was of small size and sedimented as a broad peak at about 8–10*S* (ref. 1). When steps were taken to reduce enzyme degradation, rapidly labelled RNA showed a very heterogeneous distribution with fractions sedimenting at 6–8*S*, 14–16*S* and heavy chains at 16–30*S* (refs. 2 and 3). The heavy chains of rapidly labelled RNA could be dissociated to 18*S* by centrifugation in gradients of sulpholane, a compound known to decrease interactions between ribosomal components[4]. There is also evidence that *m*RNA may become fragmented by sonication. Thus *m*RNA labelled with ^{3}H-uridine from *E. coli* which sedimented at 10–12*S* became fragmented by sonication to chains sedimenting at 4*S* (ref. 5).

Chromatography of RNA on columns of methylated albumin (MAK)[6] resolved rapidly labelled RNA from *E. coli* into several fractions which eluted around the

16*S* and 23*S* peaks of ribosomal RNA (*r*RNA) (refs. 2 and 7). It has since been shown, however, that the use of methylated albumin columns for the determination of the size of *m*RNA is unreliable. *m*RNA molecules have been found to complex with *r*RNA molecules at sodium chloride concentrations needed for elution of the latter[3].

We have found that the sedimentation behaviour ascribed to *m*RNA from *E. coli* is that of chains of rapidly labelled RNA fragmented by mechanical shear, and that sedimentation properties of non-fragmented rapidly labelled RNA chains are similar to those of ribosomal RNA.

We used *E. coli B/u* in growth conditions similar to those described before[8]. The pulse-labelled cells (see figure legends for details of labelling) were poured over frozen and crushed 10^{-2} M *tris* buffer, *p*H 7·75, containing $1·5 \times 10^{-2}$ M magnesium ions and collected by centrifugation in the cold. For the preparation of RNA we used spheroplasts and extracts obtained by alumina grinding or sonication.

The spheroplasts were prepared by a slight modification of the procedure of Kohn[9]. The cells with rapidly labelled RNA were washed by centrifugation in the cold in 10^{-2} M *tris* buffer, *p*H 7·75, containing $1·5 \times 10^{-2}$ M magnesium ions and 30 per cent sucrose, and resuspended in the same buffer (0·5 ml. of the buffer per 6×10^{10} cells). Lysozyme (1 mg/ml. of the cell suspension) was added and the cells were twice frozen in a solid carbon dioxide–acetone bath and thawed in an ice bath. After centrifugation in the cold the spheroplasts were gently resuspended using a wide bore pipette in 10^{-2} M *tris* buffer, *p*H 7·4, containing 10^{-2} M magnesium ions (*tris*-Mg buffer) and lysed by adding 0·1 of their volume of 15 per cent sodium dodecyl sulphate and incubating the mixture for 1 min at 0° C (3 ml. of the lysing solution per 6×10^{10} of the cells).

For sonication, spheroplasts or whole cells in *tris* Mg buffer or purified RNA in 5×10^{-3} M *tris* buffer, *p*H 7·4, containing 10^{-1} M NaCl and 10^{-3} M ethylenediamine tetraacetic acid (EDTA), were routinely disrupted for 1·5 min at 4° C in the 20 kHz MSE ultrasonic disintegrator with an output of 60 W using the 19 mm probe with a 9·5 mm tip. For alumina grinding, cells were ground with twice their weight of alumina in the cold and extracted as described previously[8].

RNA from the lysed spheroplasts and bacterial extracts obtained by alumina grinding or sonication was prepared as follows. To 3 ml. of the cell lysates or extracts, 3 ml. of freshly distilled 90 per cent (v/v) phenol was added. The phenol mixture in stoppered glass centrifuge tubes was gently agitated by turning the tubes upside down for 2–5 min in the cold and centrifuged at 10,000*g* for 10 min. The upper aqueous layer was carefully collected and freed from phenol by repeated ether extractions. The dissolved ether was removed by air blowing and the solution was incubated with 10 μg/ml. of RNase-free DNase for 20 min at 4° C. Thereafter 100 μg/ml. of pronase was added, the mixture was reincubated at 37° C for 20 min and the RNAs were precipitated with two volumes of ice-cold 95 per cent (v/v) ethanol. The product was stored at −20° C.

Sedimentation behaviour of RNA was studied by centrifugation in linear sucrose density gradients 5–20 per cent (w/v) in suitable buffer and ionic conditions (as listed in the figure legends). Gradients were run in the Spinco model *L* ultracentrifuge with the *SW* 39 rotor at 37,000 r.p.m. for 4 h at 4° C. From each gradient, between twenty-five and thirty fractions were collected. Optical density and trichloroacetic acid precipitable radioactivity of each fraction were determined[8].

We determined the recovery of radioactivity in the final RNA product, to make sure that our methods do not cause selective extraction of a special class of rapidly labelled RNA. If the total trichloroacetic acid-insoluble radioactivity in whole cells is taken as 100 per cent, the RNA isolated from lysed spheroplasts and from extracts obtained by alumina grinding and sonication contained 92 per cent, 84 per cent and 80 per cent of radioactivity, respectively.

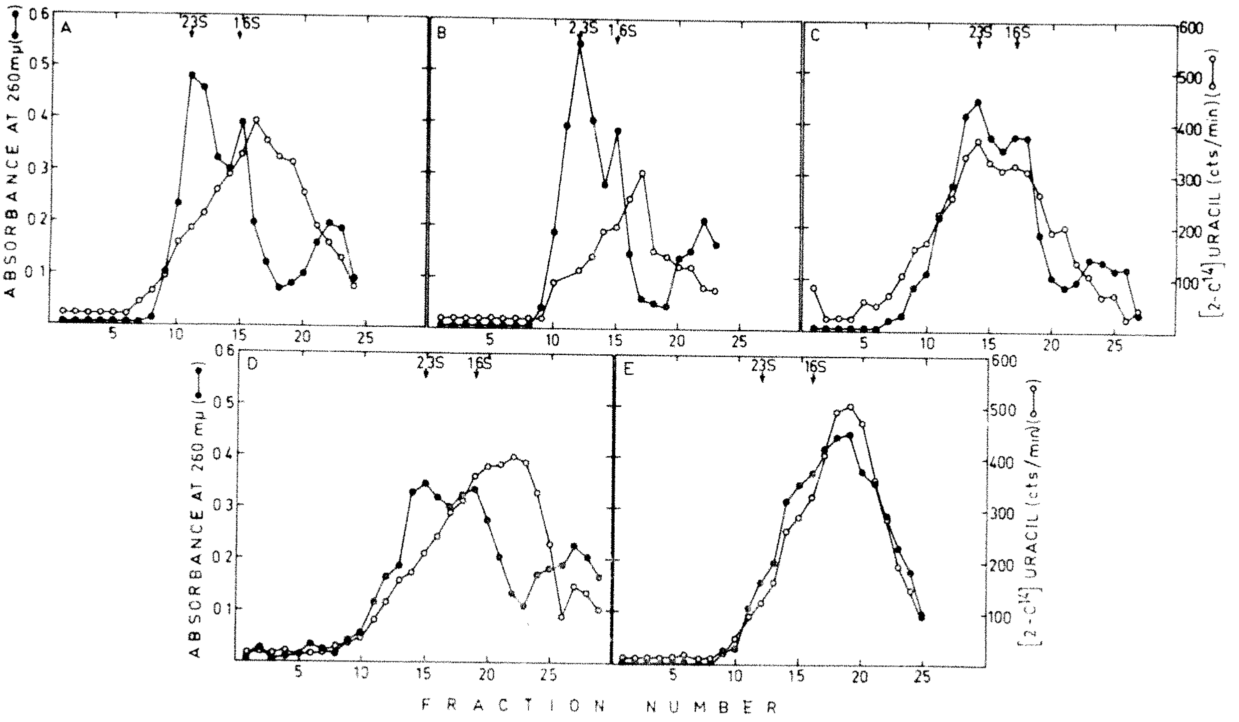

Fig. 1. Sedimentation behaviour of rapidly labelled and ribosomal RNA from *E. coli*. Influence of the method of RNA preparation. Cells were pulse-labelled with 0·1 μCi/ml. of 2-^{14}C-uracil for 1/140th of the generation time. The RNA samples were dissolved in 5×10^{-3} M *tris* buffer, *p*H 7·4, containing 0·1 M sodium chloride and 10^{-3} M EDTA. Sucrose solutions used to prepare the gradients were made in the same buffer. RNA obtained from: *A*, sonicated cells; *B*, cells ground with alumina; *C*, spheroplasts; *D*, sonicated spheroplasts; *E*, spheroplasts sonicated after phenol extraction and ethanol precipitation.

Figs. 1*A* and *B* show the sedimentation behaviour of ribosomal and rapidly labelled RNA prepared from bacterial extracts obtained by sonication and alumina grinding, respectively. The ultraviolet-absorbing material comprising the two *r*RNA components and transfer RNA is well resolved into three fractions sedimenting at 23*S*, 16*S* and 4*S*. The rapidly labelled RNA has a mean sedimentation coefficient in the range of 10–12*S* with a second rather ill-defined peak at about 8*S*.

Fig. 1*C* shows the sedimentation behaviour of a similar RNA preparation obtained from *E. coli* spheroplasts. Isotope distribution is now coincident with the distribution of material which absorbs at 260 mμ, and both sediment as two peaks with sedimentation coefficients of 23*S* and 16*S*. When the spheroplasts were subjected to sonication, rapidly labelled RNA fragmented (Fig. 1*D*).

Fig. 1*E* shows the sedimentation behaviour of RNA preparations obtained from *E. coli* spheroplasts and subsequently sonicated. It is evident that deproteinized ribosomal RNA is as susceptible to mechanical shear as is rapidly labelled RNA. It can be seen that purified ribosomal RNA was fragmented by sonication and sedimented as a broad peak at about 10–12*S*.

Although the sedimentation behaviour of ribosomal RNA is largely unaffected by the method of extraction, ionic strength and bivalent cation concentration of the medium and of sucrose gradients strongly influence the tertiary and/or secondary structure of ribosomal RNA components and their capacity to form complexes between themselves and with rapidly labelled RNA[10-12]. We have therefore compared the sedimentation behaviour of non-fragmented ribosomal RNA with that of non-fragmented and sheared rapidly labelled RNA chains in media which induce changes in the sedimentation behaviour of the former.

Fig. 2*A* shows that in media of moderate ionic strength, fragmented rapidly labelled RNA obtained from sonicated cells of *E. coli* sediments as a single peak at about 10–12*S*. In the presence of magnesium ions (Fig. 2*B*), complex formation between ribosomal RNA components and between ribosomal RNA and rapidly labelled RNA chains occurred. The rapidly labelled RNA gave a poorly resolved profile in which the radioactivity was spread along the entire sucrose gradient. The same conclusions based on similar experiments have recently been reported by Asano[3] and Hayes *et al.*[12].

Fig. 2*C* shows the sedimentation behaviour of a similar RNA preparation run in sucrose density gradient at low ionic strength in the presence of EDTA. Ribosomal RNA sediments as a single peak at about 16*S*. The behaviour of fragmented rapidly labelled RNA, however, remained unaltered and it sedimented as a broad peak at about 8–10*S*.

Figs. 2*D*, *E* and *F* show the sedimentation behaviour of non-fragmented rapidly labelled RNA in sucrose density gradients of moderate ionic strength, in the presence of magnesium ions and at low ionic strength in the presence of EDTA, respectively. In these conditions, the isotope distribution is coincident with the distribution of the material which absorbs at 260 mμ and both sediment as two peaks with sedimentation coefficients of 23*S* and 16*S* in gradients of moderate ionic strength, as 39*S*, 28*S* and 16*S* in the presence of 10^{-2} M magnesium ions and as a single peak at about 16*S* at low ionic strength in the presence of EDTA.

Figs. 1*C* and 2*D* show that in addition to the bulk of rapidly labelled RNA which sediments at 23*S* and 16*S* there is a fraction of radioactivity sedimenting as a broad zone at about 10–12*S*. This may indicate that in spite of strict precautions a small proportion of rapidly labelled RNA became fragmented. On the other hand, the material sedimenting behind the 16*S* peak may represent RNA chains in the process of being synthesized. To distinguish experimentally between the two possibilities, we have examined the sedimentation behaviour of non-fragmented RNA chains labelled during pulses of various length.

The results of a typical experiment are shown in Fig. 3. Most RNA chains labelled during 10 seconds (Fig. 3*A*) are already resolved into two fractions which sediment at 23*S* and 16*S*. A fraction of radioactivity (about 20 per cent

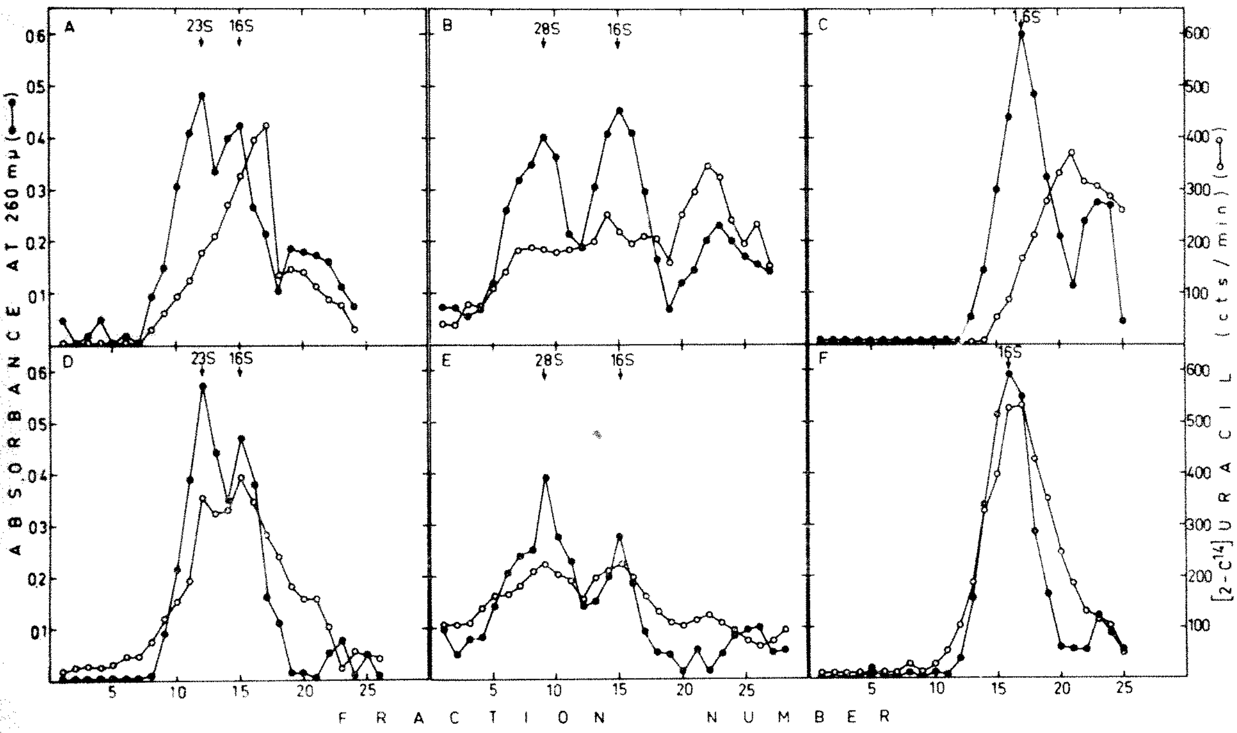

Fig. 2. Sedimentation behaviour of rapidly labelled and ribosomal RNA from *E. coli*. Influence of ionic strength and bivalent cation concentration. Cells were pulse-labelled with 2-^{14}C-uracil for 1/140th of the generation time. RNA was prepared from sonicated cells (*A*, *B* and *C*) and from spheroplasts (*D*, *E* and *F*). The RNA samples were dissolved and centrifuged in sucrose gradients containing: *A* and *D*, 5×10^{-3} M *tris* buffer, *p*H 7·4, 0·1 M NaCl and 10^{-3} M EDTA; *B* and *E*, 5×10^{-3} M *tris* buffer, *p*H 7·4, and 10^{-2} M magnesium ions; *C* and *F*, 5×10^{-3} M *tris* buffer, *p*H 7·4, and 10^{-3} M EDTA.

of total) sediments as a broad peak behind 16*S*. After longer periods of labelling the fraction of rapidly labelled RNA of low sedimentation coefficient decreases with a concomitant increase in the radioactivity sedimenting at 23*S* and 16*S*. These results suggest that the non-fragmented rapidly labelled RNA of low sedimentation coefficient represents incomplete RNA chains in the process of being synthesized.

The data presented in this work indicate that: (1) unlike *r*RNA, rapidly labelled RNA becomes fragmented by exposing cells to mechanical shear; (2) deproteinization makes ribosomal RNA susceptible to mechanical shear; and (3) the sedimentation behaviour of non-fragmented rapidly labelled RNA is similar to that of non-fragmented ribosomal RNA.

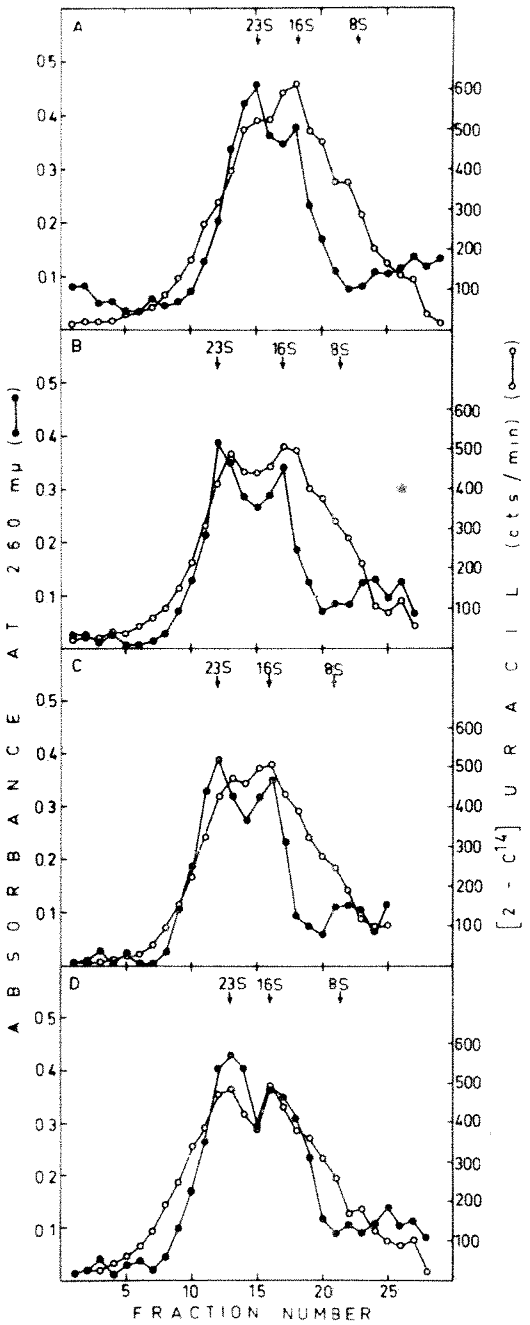

Fig. 3. Sucrose gradient profiles of RNA labelled for different periods of time. RNA was extracted from spheroplasts. Cells were labelled with 2-^{14}C-uracil: *A*, 0·3 μCi/ml. of cells for 10 s; *B*, 0·15 μCi/ml. of cells for 20 s; *C*, 0·1 μCi/ml. of cells for 30 s; *D*, 0·066 μCi/ml. of cells for 40 s. The RNA samples were dissolved in 5×10^{-3} M *tris* buffer, *p*H 7·4, containing 0·1 M sodium chloride and 10^{-3} M EDTA. Sucrose solutions used to prepare the gradients were made in the same buffer.

It has been shown that a large percentage of the rapidly labelled RNA moiety represents newly synthesized ribosomal RNA[13,14] associated with 30*S* and 50*S* ribosomal sub-units[15,16], the remaining apparently being *m*RNA. The data presented here indicate that non-fragmented rapidly labelled RNA cannot be resolved into *r*RNA and *m*RNA components by sedimentation analysis, because they both sediment at a similar rate in sucrose gradients of different ionic composition.

Ribosomal RNA in mature ribonucleoprotein remains intact in conditions when newly synthesized RNA is sheared and becomes susceptible to mechanical shear after deproteinization. Similar results on the resistance and susceptibility of these two classes of RNA towards nucleases were recently reported[8,17]. It should therefore be assumed that the interaction of protein and RNA in mature ribonucleoprotein gives protection to the RNA moiety against mechanical shear and the action of degradative enzymes, and that maturation of the ribosome involves qualitative and quantitative alterations or both in the protein–RNA interaction. These alterations lead to resistance of *r*RNA to agents which may endanger the integrity of the ribosome and impair its function.

Inhibition of Leucine and Lysine Aminopeptidase by Atopic Allergens

MANY atopic allergens—the biologically active substances involved in the syndrome of atopy in man (asthma, hay fever, atopic eczema)—have been shown to incorporate 1-deoxy-2-ketose side chains attached at the sugar carbon C1 to the ε-amino groups of lysine residues in the peptide chain of the protein or glycoprotein carrier molecules[1-3]. Recent syntheses have shown that the selective coupling of reducing sugar to the ε-amino functions of lysine side chains in the β-lactoglobulin molecule does in fact increase the specific activity of the protein during skin tests in milk-sensitive individuals[4]. The blockade of a few amine or amide groups by combination with monosaccharides would also provide a plausible explanation for the occurrence of, and for the physicochemical difference between, the "iso-allergens" in extracts of grass pollen[5].

The initial allergen–reagin interaction in hypersensitive individuals ultimately causes the local or systemic release of a number of pharmacologically active substances, among which are the peptides kallidin-10 and bradykinin. These kinins, which are vaso-active and which stimulate smooth muscle, are usually rapidly inactivated by specific enzymes, that is, by the converting enzyme aminopeptidase *B*, and by the kininase carboxypeptidase *N* which cleaves the C-terminal arginine of bradykinin[6]. The aminopeptidase is capable of releasing the N-terminal lysine of kallidin-10, converting it into bradykinin, but it has been reported to be unable to hydrolyse the arginine–prolyl bond at the N-terminal end of bradykinin[7]. At the site of inflammation, proteolytic enzymes (presumably activated by the antigen–antibody complex) are thought to act on an α_2-globulin substrate to release the active peptide kallidin-10, which must first be converted into bradykinin before the pharmacological activity can be completely abolished[8].

On the hypothesis that the active site of aminopeptidase *B* might be susceptible to inhibition by large molecules carrying sugar-substituted lysine residues, we have studied the influence of several atopic allergens on the reaction between the substrate L-lysyl-β-naphthylamide and commercial preparations of leucine aminopeptidase as a source of the enzyme. Although they are highly purified, these preparations (extracted bovine lens and extracted pig kidney, Seravac Laboratories) hydrolysed all three substrates which were tested—the β-naphthylamides of L-leucine, L-lysine and L-arginine—the turnover rates being approximately in the proportion 5 : 6 : 4, respectively.

The reaction system contained 0·1 mg of the lyophilized enzyme, 0·2 ml. of L-lysyl-β-naphthylamide carbonate (0·2 μmole) and quantities up to 1 mg of allergen in a final volume of 2·3 ml. of *tris*(hydroxymethyl)aminomethane–hydrochloric acid buffer (0·1 molar, *p*H 7·0). The tubes were shaken for 1 h at 37° C and the reaction was stopped by the addition of 1 ml. of 0·1 per cent fast garnet GBC salt in 1 molar sodium acetate buffer *p*H 6·5. Exactly 30 min was allowed at room temperature for full colour development, and the extinction of the samples was finally read at 525 nm. Sets included blanks for enzyme and reagent absorption, for allergen absorption at 525 nm and for spontaneous decomposition of the substrate. A series of standard solutions containing the substrate in different concentrations served for calculation. The degree of enzyme inhibition was plotted against allergen concentration and the point of 50 per cent inhibition was read from these curves by intrapolation.

All atopic allergens which were investigated were found to inhibit the hydrolysis of L-lysyl-β-naphthylamide by the enzyme samples, the degree of inhibition being less pronounced with the leucyl- and arginyl-β-naphthylamides as the substrates. The inhibiting capacity for a given amount of enzyme varied considerably, however, among different atopic allergens. A plot of the quantity of allergen causing 50 per cent inhibition against the ratio of the extinction coefficients in the ultraviolet *E*305/*E*280 (Fig. 1) shows at once that the inhibiting power is a function of the number of lysine–sugar determinants in the peptide moieties of the respective allergens; the extinction coefficient at 305 nm has been shown to be indicative of the 1·2-enol tautomer of the 1-deoxy-2-ketose blocking the lysine residues[1–3]. The most highly pigmented allergens—kapok, feathers and house dust—were among the most potent inhibitors. Assuming a molecular weight of 30,000 for the kapok allergen and of 300,000 for the leucine aminopeptidase, the molecular ratio of allergen : enzyme for 50 per cent inhibition was calculated to be approximately 2 : 1. Conversely, the inhibiting capacity decreases in a hyperbolic function with a diminishing number of blocked lysine ε-amino groups in the allergens and model compounds (Fig. 1). The observation that the synthetic model compound 1-(*N*)-deoxy-ribulose bovine serum albumin inhibited the enzyme, in contrast with the crystalline parent protein, indicates that the active site of the aminopeptidase is indeed sensitive to the lysine–sugar conjugate.

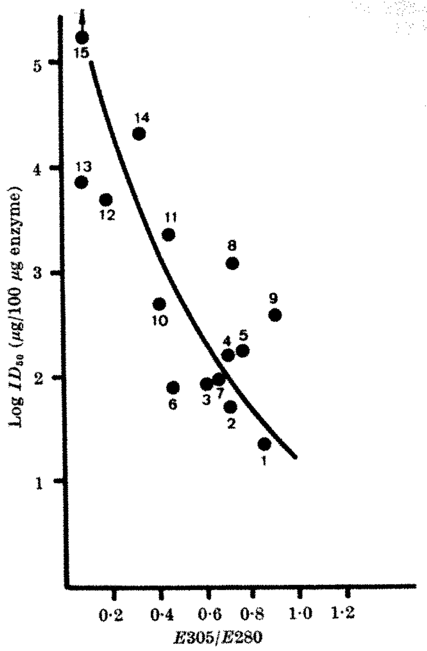

Fig. 1. Graph showing the relationship between inhibiting capacity (dose for 50 per cent inhibition in μg/100 μg of leucine aminopeptidase, log scale) and the approximate number of lysine-sugar residues of atopic allergens (see text). Key: (1) kapok KP-C; (2) feathers FE-B; (3, 4, 5) house dust (fractions E, B and D, respectively); (6, 7, 8) human dandruff (fractions E, D and B respectively); (9) pyrethrum (dialysed extract); (10) ipecac (fraction D); (11) timothy pollen (precipitate 0·3–0·8 saturated ammonium sulphate); (12) horse dandruff (dialysed extract); (13) ovomucoid (extracted hen's eggs); (14) deoxyribulose bovine serum albumin; (15) crystalline bovine serum albumin. For allergens and fractions see refs. 1–3.

Although identical results were obtained during studies of aminopeptidase inhibition in human sera, inactivation of the enzyme converting kallidin-10 into bradykinin can only be a side-effect of the biological action of allergens in man, if only because the most strongly pigmented allergens do not necessarily exhibit the highest reactivity in skin tests. Moreover, no significant differences were detected in the level of serum aminopeptidases between groups of normal and allergic human donors, nor in the behavioural pattern of these enzymes with regard to inhibition by allergens. Both normal and atopic individuals are, of course, exposed to environmental allergens to the same extent, and this would cause no difference in the degree of enzyme inhibition between the two groups of subjects. The interference of atopic allergens with the action of an enzyme which is essential for the rapid breakdown of active kallidin-10 might, however, conceivably intensify the traumatic response of allergic individuals to the triggering allergen–reagin interaction.

No results have yet been obtained with the kininase carboxypeptidase *N*, but experiments with crystalline pancreatic carboxypeptidase *B* hydrolysing hippuryl-L-lysine, a substrate of carboxypeptidase *N*, showed that the enzymatic activity was unimpaired in the presence of any of the atopic allergens which were investigated.

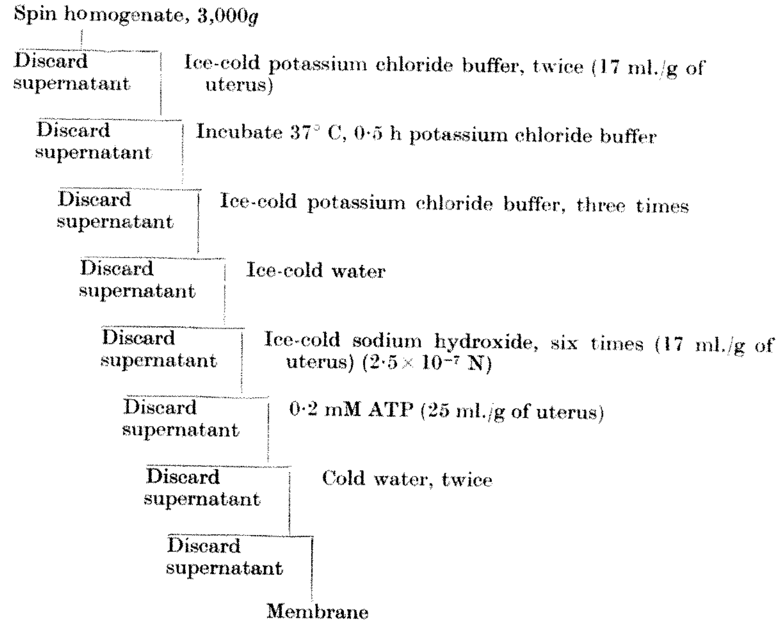
Cell Membrane of Uterine Smooth Muscle

We wished to isolate the cell membranes of the smooth muscle of the uterus for investigation of the sialic acid components (see following communication) and have therefore applied the method of Rosenthal, Edelman and Schwartz[1], which is a modification of McCollester's method for emptying broken skeletal muscle cells[2]. The uterine muscle cells are small, tapering and enmeshed in collagen so that the tissue is too tough to be disintegrated in a blender. We therefore protected the uterine horns against the effects of freezing by impregnating with glycerol[3], and then froze them between slabs of solid carbon dioxide and scraped off the endometrium. Frozen muscle segments are made into a block with drops of 50 mM calcium chloride, and sectioned on a freezing microtome. The mush on the knife was periodically transferred to 50 mM calcium chloride at 0° C and this homogenate was freed of cell contents by modifying Rosenthal's method as in Fig. 1. The membranes sedimented readily during centrifugation because the collagen fibres were retained; if they did not settle after the ATP treatment, but remained as a fluffy dispersion, then phase-contrast microscopy showed that they were still surrounded by extruded protein containing nuclei and mitochondria, and a second ATP treatment was necessary.



Spin homogenate, 3,000g
Discard supernatant
Ice-cold potassium chloride buffer, twice (17 ml./g of uterus)
Discard supernatant
Incubate 37° C, 0·5 h potassium chloride buffer
Discard supernatant
Ice-cold potassium chloride buffer, three times
Discard supernatant
Ice-cold water
Discard supernatant
Ice-cold sodium hydroxide, six times (17 ml./g of uterus) ($2{\cdot}5 \times 10^{-7}$ N)
Discard supernatant
0·2 mM ATP (25 ml./g of uterus)
Discard supernatant
Cold water, twice
Discard supernatant
Membrane

Rats were treated with diethylstilboestrol 75 μg/day for 6 days before killing.

Fig. 1. Procedure for isolating myometrial cell membrane

Absence of mitochondria in the final membrane product was confirmed by electron microscopy[4]. By phase-contrast microscopy, the emptied tissue sections resembled a network of holes, as would be expected for rings of empty membrane held together by the surrounding collagen fibres, and did not resemble skeletal muscle sarcolemma tubules[1,2,5,6]. This is not surprising because of the method of comminution and the structural differences between large, easily separated skeletal muscle fibres and small tapering smooth muscle cells enmeshed in collagen. The ratio of cell surface area to cell volume is ten times greater for uterine muscle than for skeletal muscle[7] and so contamination of the membrane preparation is less of a problem.

Table 1. COMPOSITION OF MYOMETRIAL MEMBRANE

	% Dry weight of total membrane Average values
Nitrogen	13·4
Phosphorus	1·2
Collagen	58·1
Hydroxyproline	4·9
Lipid	13
Total sialic acid	0·52
Non-lipid sialic acid	0·43
Phospholipid phosphorus	0·27
Cholesterol	1·6
Proteolipid protein	0·5

Nitrogen, phosphorus, collagen[9] and hydroxyproline[10] were estimated in the dried membrane. The lipid was obtained by extracting dried membrane with chloroform–methanol 2 : 1 v/v (0·5 ml./mg) for 3 h at 24° C and, after removal of the solvent, the lipid was analysed for phospholipid phosphorus[11,12], cholesterol[13] and proteolipid protein[14]. Sialic acid was estimated by direct Ehrlich reaction[15].

Table 1 gives analyses of this membrane preparation. The chloroform–methanol soluble portion (13 per cent) was shown to be predominantly lipid, not proteolipid, by the occurrence of only 4 per cent protein in this fraction. Wallach has expressed serious doubt that the lipoprotein plasmalemma is obtained in McCollester's method, because of the use of low ionic strength solutions[8]. That this doubt is unfounded is shown by the analyses for cholesterol and phospholipid in the uterine smooth muscle membrane; the molar ratio of cholesterol to phospholipid averaged 0·47. Table 2 shows the relative proportions of the various phospholipids. The analyses for this membrane preparation are in reasonable accord with the results for various other plasma membranes.

The electrolyte composition of the membrane is interesting because of the high ratio of sodium to potassium, and this was independent of the use of the sodium salt of ATP in the last stage of the preparation (Table 3). Even if the membrane had bound every sodium ion available during the preparation with sodium hydroxide, it could have

Table 2. PHOSPHOLIPID COMPOSITION OF MYOMETRIAL MEMBRANES

Phospholipid	% Total recovered phosphorus
Solvent front (everything above P.E.)	2·3
Phosphatidyl ethanolamine (P.E.)	24·8
Phosphatidyl serine	6·4
Phosphatidyl choline	50·3
Sphingomyelin (S)	13·8
Everything below S	2·5

The phosphorus content of each spot on a silica gel thin layer chromatogram of the lipid extract was estimated by the molybdate method[11,13].

Table 3. ELECTROLYTE COMPOSITION OF MYOMETRIAL MEMBRANES

	Membrane preparation		
Electrolyte	ATP sodium salt	ATP *tris* salt	
Mg	3·0	3·6	3·3
Ca	4·4	4·1	3·9
K	2·1	1·5	1·0
Na	74·7	71·0	78·0

Expressed as mM/kg dry weight of membrane. Tissues were dried, digested with nitric acid and analysed by flame photometry.

obtained only approximately 1 mM/kg dry weight. The preceding stages involved potassium chloride buffer, and so we must conclude that the membrane strongly retained sodium ions despite the opportunity to exchange them for potassium ions.

Sialic Acid of Uterine Muscle Membrane: Reappraisal of the Serotonin Receptor of Smooth Muscle

WOOLLEY suggested that the serotonin receptor of uterus and stomach is a ganglioside, because neuraminidase destroys the sensitivity of those tissues to serotonin, and the sensitivity can be partially restored by the addition of brain gangliosides[1]. This assumption that a material which restores activity is the naturally occurring receptor can be questioned, and we have therefore investigated the sialic acid of the uterine muscle membrane and the occurrence or otherwise of gangliosides.

The direct Ehrlich reaction[2] for estimating sialic acid lacks sensitivity but has a high degree of specificity[3]. Applying it to gelatine (as a membrane substitute) plus *N*-acetylneuraminic acid in the appropriate ratio, we found only slight interference (2 per cent) and therefore used this reaction to estimate the membrane sialic acid; (the thiobarbituric acid method applied to mucosubstances is unreliable[4–8]). The uterine muscle membrane was prepared and the lipid portion extracted (see preceding communication) from uteri which had been preincubated in physiological salt solution, either with or without neuraminidase.

The lipid-soluble portion of sialic acid was approximately one-seventh of the total membrane sialic acid and *Vibrio cholerae* neuraminidase acted only on the non-lipid portion of the membrane sialic acid, without detectable activity on the lipid-soluble sialic acid (Table 1). With *Clostridium perfringens* neuraminidase, a difference of 1 μg of sialic acid was not significant in relation to the total quantity of sialic acid and it is not correct to consider that one-third of the neuraminidase action was on the lipid-soluble sialic acid, for it may have removed no lipid sialic acid. Sigma no longer supplies this enzyme, so we cannot confirm that *Clostridium perfringens* neuraminidase does not act on the lipid-soluble sialic acid if used for a longer time.

Table 1. ACTION OF NEURAMINIDASE ON SIALIC ACID OF MYOMETRIAL MEMBRANES

	Control	Enzyme treated	Calculated removed by enzyme
		V. cholerae	
Complete membrane	54	44	10
Lipid-free membrane	46	36	10
Calculated in lipid	8	8	
		C. perfringens	
Complete membrane	55	52	3
Lipid-free membrane	47	45	2
Calculated in lipid	8	7	

Control and enzyme-treated groups incubated for 75 min in physiological salt solution containing 1·4 mM calcium chloride, *p*H 7·15. *Vibrio cholerae* (Calbiochem) and *Clostridium perfringens* (Sigma type V) neuraminidase were added with 1·5 mM EDTA. After incubation the membranes were isolated and results expressed as μg of *N*-acetylneuraminic acid in 10 mg of complete membrane.

The release of only 3 μg of sialic acid from a total of 55 μg by *Clostridium perfringens* might explain why Woolley found this particular neuraminidase essential for his method of estimating the serotonin receptor and why the conditions he used were so critical[9]. If only a very small proportion of the membrane sialic acid was removed, then only slight conformational changes might occur in the serotonin receptor area, and gangliosides might succeed in partially reversing these conformational changes. *Vibrio cholerae* neuraminidase was more active in our experiment, removing 10 μg of sialic acid from a total of 54 μg, and presumably greater conformational changes therefore occur with the use of this enzyme, although Wesemann and Zilliken[10] could completely restore the sensitivity to serotonin of tissue treated with this enzyme by the addition of *N*-acetyl, *N*-glycolyl or *N*-carbobenzoxyneuraminic acid. These facts argue against the importance of gangliosides, as such, in restoring the sensitivity to serotonin, and suggest that it is the acidic sialic acid group which is important.

Gangliosides had not been detected in rat uterus[11], and so, to obtain a greater quantity of tissue, we used bovine uteri. Bovine myometrium, dried with acetone, was extracted with chloroform–methanol, partitioned and dialysed by standard methods for preparing gangliosides. Analysis by a modification of Long's method[11] showed that the dried myometrium contained 0·017 per cent sialic acid attributable to gangliosides and thin-layer chromatography revealed spots, some corresponding with bovine brain gangliosides (Sigma type II). Thus bovine myometrium contains small quantities of gangliosides and human uterus also appears to contain them[12]; if sufficient rat uteri were used, one could probably also find gangliosides there.

Woolley's colleagues reported that the rat brain ganglioside most active in restoring the serotonin response of neuraminidase-treated smooth muscle contained a molecular ratio of galactose : glucose : stearic acid 1 : 2 : 1 (ref. 13). Gielen found only one ganglioside reversibly combined with serotonin; it had the molecular ratio 1 : 1 : 1 and bound an equimolar quantity of serotonin, but had a greater affinity for calcium[14]. Even if there should be a trace of this latter ganglioside in rat uterus and stomach, the fact that it complexes *in vitro* with serotonin does not imply that it is the natural receptor of uterine and stomach smooth muscle.

Consideration of the observations of Wesemann and Zilliken[10], and of our finding that the sialic acid of uterine membrane is chiefly in the form of glycoproteins, not lipid-soluble gangliosides, and that neuraminidase acts predominantly on the non-lipid sialic acid, leads us to believe that serious consideration should be given to the possibility that the smooth muscle receptors for serotonin are not gangliosides, but are glycoproteins containing sialic acid. Loss of sialic acid from the glycoproteins would probably result in conformational changes in the receptor areas, and it may well be that addition of sialic acids can reverse those conformational changes.

Isolation of a New Toxin from Cultures of *Aspergillus flavus*

THE mould *Aspergillus flavus* produces a wide variety of toxic metabolites and, because of its role as a frequent contaminant of some foods and feeds, its metabolites have been investigated both chemically and toxicologically[1]. Recent research on the toxic metabolites of this mould has focused on the compounds known as aflatoxins[2].

Work in our laboratories directed toward the preparative separation of the aflatoxins has resulted in the isolation of an unreported metabolite of *A. flavus* to which we have tentatively assigned the name "aspertoxin". *A. flavus* was grown on shredded wheat and the metabolites were extracted with chloroform. Addition of hexane to the chloroform extract yielded a crude precipitate which contained the aflatoxins, aspertoxin, and several highly coloured compounds. Chromatography of the crude precipitate of *A. flavus* on an acid alumina column with benzene/chloroform (1/1, v/v) gave a colourless fraction containing aflatoxins B_1, G_1 and B_2. Aflatoxins G_2 and M_1 were removed with chloroform/acetone (9/1, v/v). When the eluate containing aflatoxins G_2 and M_1 was concentrated, aspertoxin rapidly crystallized as tiny, colourless needles.

Aspertoxin was originally thought to be aflatoxin M_1 because of an equivalence of R_F values ($R_F = 0{\cdot}32$) on silica gel thin-layer chromatography plates when chloroform/acetone (9/1, v/v) was used as the developing solvent. Development of the plates with chloroform/pyridine (9/1, v/v) or chloroform/acetic acid (9/1, v/v), however, provided criteria for distinguishing the two compounds. In each case, aspertoxin moved at an R_F of 0·55–0·60 whereas aflatoxin M_1 appeared at an R_F of 0·40.

The new isolate was quite pure without further crystallization; however, it could be recrystallized from hot dioxane–water. The compound decomposed at 240°–280° C without melting, and yielded a red compound(s); the resulting mixture melted at 297°–304° C. By high resolution mass spectrometry aspertoxin was shown to have the molecular formula $C_{19}H_{14}O_7$. The compound exhibited a molecular ion peak at $m/e = 354{\cdot}074200$; the mass calculated for $C_{19}H_{14}O_7$ is 354·073949.

The infrared spectrum of aspertoxin has bands at 3,354 cm^{-1} (hydrogen-bonded OH), 1,656 cm^{-1} (C=O), 1,630 cm^{-1} (hydrogen-bonded C=O), 1,587 cm^{-1} and 1,575 cm^{-1} (phenyl), 1,133 cm^{-1} (C—O—C) and other strong bands at 1,460 cm^{-1}, 1,269 cm^{-1} and 1,103 cm^{-1}.

The ultraviolet spectrum of aspertoxin has $\lambda_{\max}^{\mathrm{MeOH}}$ 310 mμ (ε 11,400) and 241 mμ (ε 34,000). The spectrum was not affected by the addition of acid or base.

A complete structure for aspertoxin cannot be assigned on the basis of the limited chemical evidence so far elaborated. The compound is not difficult to isolate and purify; however, typical crude precipitates of *A. flavus* extracts usually contain less than 0·5 per cent aspertoxin by weight, whereas aflatoxin B_1, the most abundant aflatoxin, usually accounts for about 30 per cent of the total weight of crude precipitate. The chemical data obtained thus far show that aspertoxin is not one of the previously known metabolites of *A. flavus*.

Aspertoxin was tested for biological activity and found to have pronounced toxic effects on the developing chicken embryo. In preliminary experiments, the injection of 2·0 μg/egg into either the yolk or air cell of fresh fertile eggs killed 100 per cent of the embryos; a concentration of 0·7 μg/egg killed 50 per cent of the embryos. Aflatoxin B_1 is an unusually potent toxin in the chicken embryo, and it produces comparable mortalities in lower concentrations (LD_{50}, air cell route, 0·025 μg/egg)[3]. Nevertheless, aspertoxin must also be considered highly toxic in this system. Macroscopic examination of non-viable embryos revealed beak malformations, generalized oedema, loss of muscle tone and haemorrhage from the umbilical vessels. Whereas lethal doses of aflatoxin B_1 are effective within 3 or 4 days after injection, lethal doses of aspertoxin produce no mortality until late in the incubation period. A more detailed investigation, including histopathology, of the toxic effects of this new metabolite in the chicken embryo is in progress.

Catabolic Rate of Body Protein in Rat during the Earlier Stages of Protein Depletion

THERE have been many attempts to determine the magnitude of protein reserves or endogenous nitrogen excretion in protein-depleted or starved animals[1–5]. Previous results, however, have not clearly stated the fractional rate of catabolism of body protein itself, either for a whole body or for an individual organ or tissue. Borsook[6,7] presented the metabolic concept as a development of Martin and Robison's concept[2] that the cytoplasmic proteins constituting reserve proteins are broken down at a rate depending on their mass, or in a first-order reaction.

In this study, ten adult male Wistar rats, weighing about 450 g, were fed a protein-free diet after preliminary feeding on a 20 per cent casein diet. The percentage changes in body weight and body nitrogen during the first 16 days are shown in Fig. 1; the second set of values derived from the final body nitrogen and the nitrogen balance during experimental periods. As Fig. 1 shows, total body protein decreases exponentially with extremely little variance between individuals at any time, whereas the changes in body weight show a sigmoidal decrease with a greater variance. Such a constancy in the catabolic rate of body protein as a whole after protein deprivation could provide a useful basis for estimating protein requirements. In Fig. 2, the percentage changes in body protein, together with those in the total nitrogen content of liver and muscle, are plotted logarithmically against time for the first 40 days of the depletion. This figure seems to show that the labile body protein is composed of at least two components, both almost completely catabolized in a first-order reaction.

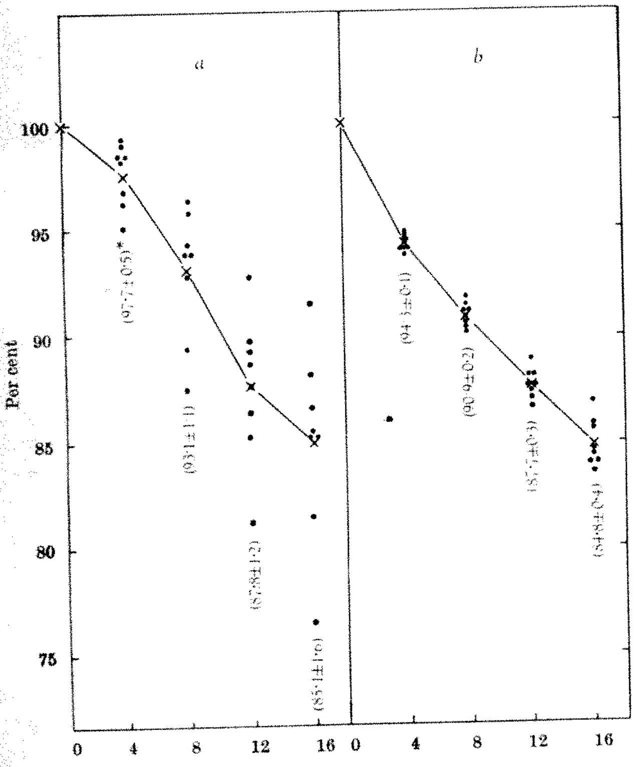

Fig. 1. Percentage changes in body weight (*a*) and body nitrogen (*b*) of adult rats during the initial stages of protein depletion. * Mean ± standard error.

By a general kinetic analysis[8], the catabolic rate per day and the content of the less labile component were first estimated to be 0·79 per cent and 97·2 per cent, respectively. Then those of the more labile component were estimated to be 83·3 per cent and 2·8 per cent, respectively. The content of the more labile component almost agrees with the so-called extra nitrogen of urine estimated by Campbell[3] and Lusk[9]. Its catabolic rate, equivalent to only 0·83 day (0·693/0·833) of half-value time, implies that this labile component should be represented by the transitive or mobile body nitrogen which could be much influenced by daily intake of protein and bear a close relation to the amount of reserve protein. The contents of the more labile component in liver and muscle were similarly estimated to be 30·6 per cent and 6·6 per cent, respectively.

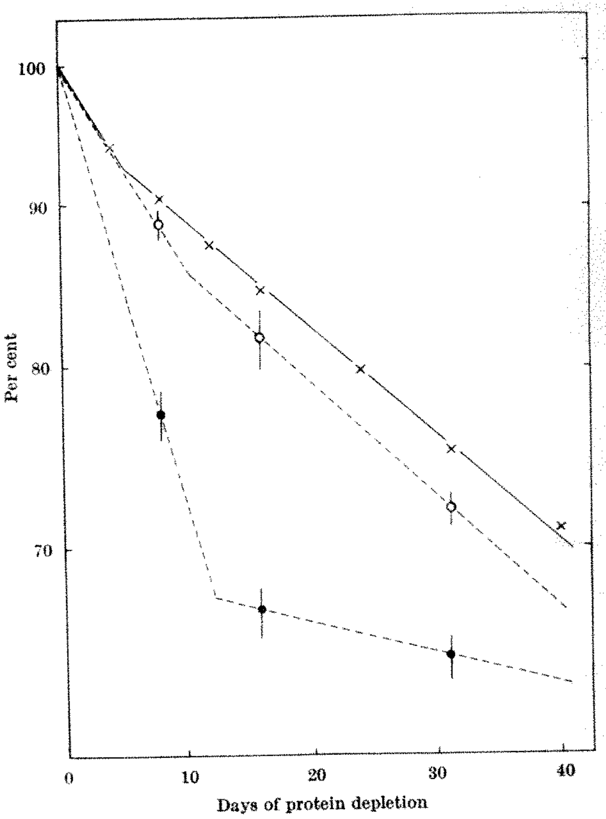

Fig. 2. Logarithm of total percentage changes in body, liver and muscle nitrogen in adult rats during the earlier stages of protein depletion. ×, Body nitrogen; ○, muscle nitrogen; ●, liver nitrogen. Vertical lines represent standard error.

We have tried to estimate roughly the protein requirements for maintaining such a normal level of body protein. Because the content of body nitrogen of rats was approximately 3·00 per cent of body weight, their protein content is 18·75 per cent. We therefore suggest that 437 mg (18·75 g × 0·028 × 0·833) of body protein is catabolized each day as a more labile component, and 144 mg (18·75 g × 0·972 × 0·0079) as a less labile component. A total of 581 mg of protein should therefore be supplied in a diet for each 100 g of body weight, corresponding to 830 mg if the value for net protein utilization[10] of the dietary protein is 70. In this experiment, the rats consumed about 25 g of diet daily, so that these protein requirements correspond to about 15 per cent of the diet (0·830 g × 4·5/25 g).

Changes in Collagen Cross-linking in Rats with Reduced Food Intake

THERE have been several reports that decreased food intake blocks collagen cross-linking in rats[1,2]. The resulting collagen network is described as younger tissue. Comparing this observation with the classical experiments of McCay[3], who increased the life span of experimental animals by reducing their food intake, it seems that a more detailed study of the cross-linking processes is desirable. As far as we know, no data are available which specify the cross-links that are blocked in animals whose food is restricted. Even the fact of whether this change in collagen structure involves only some of the cross-links between the three polypeptide chains of the tropocollagen molecule, or whether it results in a random decrease in cross-link formation, has not yet been investigated.

Two approaches were chosen to answer these questions: (*a*) chromatographic separation of the alpha collagen polymers; and (*b*) estimation of the free carbonyl compounds in the soluble and insoluble collagen. The second approach was partly influenced by the findings of Milch *et al.*[4] on the role of some products of intermediary metabolism (chiefly aldehydes) as potential cross-linking agents and partly by our own results[5,6] on the presence of keto-acids and an unknown aldehyde component in collagen. It was reported earlier that the molar ratio of these compounds is changed, as the soluble collagen is converted into the insoluble network[6].

The average food intake of male Wistar rats was estimated at monthly intervals in rats of different ages. An experimental group of animals was restricted to 60 per cent of the control intake of food, and the control group was given standard pelleted (Larsen) food freely. The animals were 60 days old at the beginning of the experiment and were killed when they were 210 days old.

To prepare skin collagen, the hair was shaved off, the skin was freed of subcutaneous tissue and acid soluble collagen was prepared according to the procedure of Drake *et al.*[7]. Acid soluble collagen was denatured by heating to 50° C just before analysis, and the denatured product was separated by column chromatography on carboxymethyl cellulose. The separation technique used was essentially the same as that described by Veis and Anesey[8].

In the estimation of carbonyl compounds, both acid soluble and insoluble collagen were used. Insoluble collagen had to be dissolved before analysis; this was done by pronase treatment according to the procedure of Drake *et al.*[7]. Carbonyl compounds in the dialysable fraction after treatment with pronase were converted into the corresponding 2,4-dinitrophenylhydrazones and were separated on silica gel chromatographic sheets (Eastman Kodak *K* 301 *M*) in the following solvent systems: (*a*) chloroform–benzyl alcohol–acetic acid (70 : 30 : 3); (*b*) toluene–pyridine–ethylene–chlorhydrine–0·8 molar ammonia (100 : 30 : 60 : 60, upper phase).

A typical carboxymethyl cellulose chromatogram of the acid soluble collagen preparation from food restricted animals and animals fed freely is shown in Fig. 1. If the individual peaks are compared it is evident that there is no qualitative difference between both preparations; there are, however, differences in the quantity of individual polymers. The amount of all polymers except beta-22 and gamma-222 is clearly much smaller in the collagen preparation from food restricted animals and the so-called delta fraction is also slightly increased. This indicates that the formation of all cross-links is decreased, with the exception of those between two alpha-2 fractions which are not affected. The role of the cross-link between alpha-2 fractions has already been shown in hypophysectomized rats, where this type of cross-link is the only one which persists[9]. If the results of food restriction are compared with those of hypophysectomy, it is evident that whereas hypophysectomy results in an almost complete block of cross-link formation, which is very specific in allowing only gamma-222 formation, the effect of food restriction seems to be more random. We tried to classify the nature of this cross-link. Table 1 shows that the total number of carbonyl compounds is decreased from seven to almost five per mole and that this decrease occurs because of the free keto-acids. The total number of aldehyde components is not changed. Our results show the following. (*a*) Food restriction results in a less polymerized acid soluble collagen; the polymerization of alpha-2 fractions is apparently not affected whereas the cross-link formation between alpha-1 and alpha-2 and two alpha-1 fractions is markedly decreased. (*b*) The formation of the alpha-2–alpha-2 cross-link is either independent of the carbonyl compounds present in the tropocollagen molecule, or the presence of the carbonyl compound involved in cross-linking cannot be influenced by restricted food intake. (*c*) On the contrary, the total number of carbonyl compounds with free carbonyl groups tends to decrease to five in the insoluble fraction which is the number found in acid soluble collagen. This means that

Table 1. DINITROPHENYLHYDRAZINE-REACTIVE SUBSTANCES PRESENT IN THE COLLAGEN PREPARATIONS FROM CONTROLS AND FOOD RESTRICTED ANIMALS (MOLE PER MOLE OF TROPOCOLLAGEN, MOLECULAR WEIGHT OF TROPOCOLLAGEN CONSIDERED 260,000)*

Anti-metabolic Extract from the Brain of *Protopterus aethiopicus*

It has been suggested that the brain of the aestivating lung-fish might contain an anti-metabolic agent[1], perhaps not unlike the mono-amines secreted in the pons and medulla of cats as active agents in the control of sleep[2].

Large lung-fish (2–6 kg) from Uganda were flown by jet to Denver, then placed in aquaria at Fort Collins, Colorado, in water 4–16 in. deep over specially collected mud. The constant temperature room was maintained at 24°–25° C. When the fish were accustomed to their new environment and were eating well, they were forced to encyst in the underlying mud by simply withdrawing a portion of the water from the aquarium each day until it was quite dry and the mud was caked hard. The fish dug their chambers at the bottom of tunnels, coiled up and entered a state of profound torpor, in every way similar to their behaviour in their normal environment in Africa during the dry season.

After the fish had been immobile for a month to 6 weeks, the mud was chipped away and an attempt was made to kill the fish abruptly without arousal. It is presumed that all fish had reduced metabolism. The oxygen consumption of one was successfully measured. In the resting–active state before encystment, the oxygen consumption was 30·7 ml./h/kg, whereas after 30 days in the mud, the consumption was 4·6 ml./h/kg, a drop of 85 per cent.

The head was severed from the body with a meat cleaver, and the brain immediately dissected from the skull and placed in acetone in a bottle packed in chipped ice. The entire brain was extracted on the same day using the methods described by Guillermin *et al.*[3]. The extract emerged as a buffered solution (pH 7·0) of 2 ml. volume.

The extract was injected intravenously into fasting white Wistar rats, contained in a 2 l. dark glass bottle with constant forced ventilation at 200 ml./min. The state of consciousness, rectal temperature, oxygen consumption and carbon dioxide production were monitored. Heat production was calculated from the amounts of oxygen consumed per unit time and the RQ according to the formula: HP (kcals/mol O_2) = 87 + 27 RQ. Readings were continued hourly or at irregular intervals for as long as was deemed desirable.

The following experiments were performed. (*a*) For the controls 2 ml. was injected of: (1) the extracting fluid; (2) and (3) extracts from the brains of two active fish (No. 1 and No. 2); (4) and (5) extracts from the brains of two torpid fish which were aroused and struggled for several minutes before being subdued and killed (No. 3 and No. 4). (*b*) For the protocols 2 ml. was injected of: (6) extract of brain of torpid fish No. 5; (7) combined extracts of brains of fish No. 6 and No. 7. The metabolic data are presented as a family of curves in Fig. 1. Each curve represents observations of 1 h plotted against time for each test animal, numbered as listed here. The "injection period" was variable, but represents the period of time the rat was out of the bottle for the injection procedure.

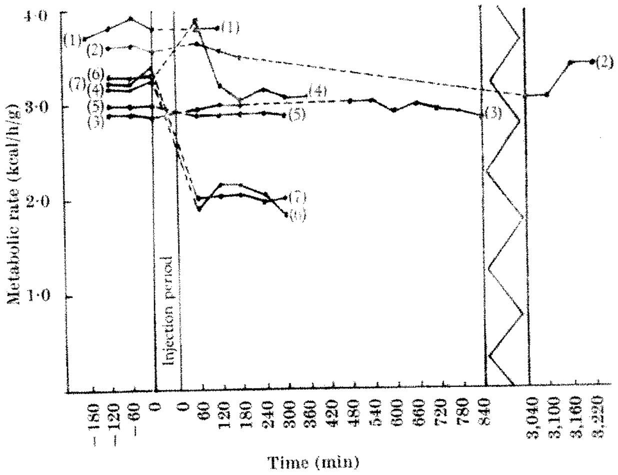

Fig. 1. Curves representing the data obtained from injection of rats.

None of the control extracts affected the injected rat in any observable or measured way. The response to extracts from the brains of fish which had been removed before the animal was aroused from deep torpor was profound and dramatic. The rats became lethargic and did not respond normally to irritating stimuli. They refused food, the body temperature fell 5° C and the measured metabolic rate fell to 65 per cent of the pre-injection fasting level. The respiration quotient did not change significantly (0·80). The effect lasted several hours.

Although the experiments are few in number, all those in which the protocol was successfully completed induced an unequivocal response: lethargy, a 35 per cent drop in metabolic rate and a fall of 5° C in body temperature.

This work was performed under a contract between the US National Aeronautics and Space Administration and the Research Institute for Biological Sciences, Denver, Colorado.

Maximum-intensity Fluorescence Microscopy

DESPITE the high intrinsic brilliance of some modern light sources, there are many occasions on which the intensity of an image viewed through a fluorescence microscope is inadequate, leading to inability to appreciate details or to inconveniently long exposures in photomicrography. This situation is likely to become increasingly important with the further development of more specific immunofluorescence methods and of fluorescence histochemistry. The system described here approaches the maximum theoretical efficiency and the image intensity is limited only by the intrinsic brilliance of the source and by the transmission or reflectivity of the optical components. At the same time this system opens up a number of new possibilities for viewing two different components simultaneously.

In recent years several vertical-incidence illuminators have been developed or adapted for fluorescence microscopy. One such system is shown in Fig. 1. The light source (LS) (usually a high pressure mercury lamp such as the Osram *HBO* 200) is focused by means of the collector lens (L_1) onto the aperture stop of the objective O. F_1 is a suitable exciter filter (usually passing long wave ultraviolet or blue light) and M_4 is a beam-splitting mirror. For maximum efficiency, M_4 should be a dichroic (spectrum-splitting) interference filter which reflects ultraviolet and blue and transmits visible light. In this case the specimen S will be illuminated with ultraviolet or blue light and the emitted fluorescence (usually of longer wavelength) will be transmitted through M_4 to the eyepiece E. A suitable barrier filter (B) is interposed to absorb any exciting light and provide a black background. This system has the advantage that most of the unabsorbed exciting light passes through the specimen and the little that is reflected by it or by the coverglass will be reflected away by M_4. Only a relatively light barrier filter is therefore required at B. The chief disadvantage is that the objective acts as its own condenser, so that the illuminating numerical aperture varies with the objective, whereas with a conventional transmitted light system the specimen can be illuminated by means of a single condenser of high numerical aperture. Maximum illumination in the vertical incidence system usually occurs with high power objectives, for which it is most needed. It is evident that vertical incidence fluorescence illumination can be combined with transmitted light illumination through a sub-stage condenser, using a second light source. This was carried out in preliminary experiments using a second *HBO* 200 lamp, collector lens and exciter filter. Measurements carried out with a photomultiplier photometer showed that the specimen illuminations obtained were additive. A simpler and economically more attractive method using a single source is illustrated. A second collector lens L_2 is used to image the back of the mercury lamp onto the condenser aperture stop. M_1, M_2 and M_3 are fully reflecting front surface aluminized mirrors, F_2 an exciter filter. M_4 now acts as a barrier filter and reflects away any exciting light transmitted by the specimen. The Zeiss large fluorescence microscope with vertical incidence illuminator proved particularly suitable for this modification; the beam-splitter M_4 in this instrument is of the dichroic type. The rear end of the lamp housing was removed and replaced by a collector lens. Only the mirrors M_1 and M_2 had to be added. When both objective and condenser are high-aperture immersion types, the specimen is illuminated by a solid cone approaching the theoretical maximum. With smaller apertures, some increase might be obtained by using auxiliary oblique or annular illumination, but it is doubtful whether the gain would be worth while.

This system can, of course, be used for combining fluorescence with other methods of illumination, such as phase contrast. Suitably placed polarizing components make it possible to pick out birefringent elements in a fluorescent specimen. A less obvious application, not hitherto described, is to use different exciter filters F_1 and F_2 so that, for example, substances excited by ultraviolet light (such as many carcinogenic hydrocarbons) can be viewed against fluorochromed tissues excited by blue light and one or other component can be rapidly extinguished. It should also be possible to view simultaneously two different antigens stained by different immunofluorescent techniques and excited by light of different wavelengths.

Photochemical Production of Quinoid Structures in Wood

DEGRADATION of wood by a number of agencies (for example, white rot fungi[1], hot alkaline sulphite[2] or light[3]) results in a decrease in the methoxyl content of the lignin. Thus after irradiation for 1,000 h using an enclosed 1 kW carbon arc, glass-covered newspaper manufactured predominantly from *Pinus radiata* seemed to have lost about one-third of its methoxyl groups. Such a high loss suggests that, despite the very complex and variable type of structure proposed for lignin[4], a fairly simple molecular unit, which can be formed from at least 30 per cent of the lignin building stones, is involved. Evidence is presented here which indicates that this intermediate is of quinoid structure; either an *o*-quinone, a *p*-quinone, or a *p*-quinone methide.

Of these three quinoid structures, a *p*-quinone could be eliminated if the degradation did not involve atmospheric oxygen, as I have suggested[3], but more recent experiments show that, if precautions are taken to exclude oxygen, wood is not yellowed by light and retains its methoxyl content. This means that the yellowing of wood by light is a photo-oxidative process and so *p*-benzoquinones could be formed. Indeed, 2,6-dimethoxybenzoquinone shows a significant (30 per cent) decrease in methoxyl content when it is irradiated for 1,500 h in a solid film of cellulose acetate. It is not yet known whether analogous *p*-quinone methides also show a decrease in methoxyl content on irradiation, and both they and *o*-quinones, from which the methoxyl group has already been lost, could also be formed by photo-oxidation of guaiacyl–propane systems.

The spectral region[3] (3550–4000 Å) which causes yellowing of wood confirms that quinones, which are able to absorb this light, could be responsible for the degradation. The most significant evidence for the photochemical production of quinoid structures in wood, however, comes from experiments in which the free phenolic hydroxy groups in wood lignin have been protected with acetyl or methyl groups. Wood or newspaper which has been acetylated by successive immersion in aqueous sodium hydroxide (1 N) and acetic anhydride yellows slowly (Fig. 1) and does not initially (100 h) show a loss of methoxyl groups when irradiated. Similarly, wood which has been acetylated by immersion in acetic anhydride containing a trace of perchloric acid, although initially coloured by the reaction, undergoes bleaching rather than yellowing when irradiated (Fig. 1). Methylation of the wood by soaking first in aqueous sodium hydroxide (1 N) and then in warm dimethyl sulphate also markedly slows the yellowing process, particularly in the initial stages (Fig. 2). These results indicate that lignin only readily undergoes photochemical demethoxylation and yellowing when it contains free phenolic hydroxy groups. The same condition governs the formation of quinones and quinone methides and it thus seems very likely that these are formed at some stage when wood yellows. Being highly photo-reactive themselves, it is probable that they will be further degraded and are not themselves responsible for the final yellow colour of the wood. This is in agreement with attempts to remove the yellow colour of irradiated wood by reduction. While dilute aqueous sodium borohydride removes all the yellow colour, hot stannous chloride has no effect on it, and hot sodium dithionite is only partially effective.

Neither the mechanism of methoxyl loss nor the structure of the quinoid precursors in wood is known. Reflectance measurements on panels of *Pinus radiata* in this laboratory indicate that some of the suggested quinoid structures may already be present in wood, because irradiation for a few hours under glass causes an increase in the reflectance around 3700 Å. Most of the quinoid structures, however, must be generated during the process of yellowing. Because reduction of benzoyl groups in the lignin by soaking the wood in aqueous sodium borohydride does not hinder the yellowing process (Fig. 2), the suggested quinoid structures may be quinone methides formed from benzyl alcohol groups. Certainly, irradiation under glass of 4-hydroxy-diphenylmethanes in cellulose acetate films produces yellow colours attributable to stable quinone methides. On the other hand, production of *o*-quinones would neatly combine the demethoxylation and the formation of quinones in one step.

PHYSIOLOGY

Action of Procaine on Calcium Efflux from Frog Nerve and Muscle

A RECENT hypothesis about the mechanism of action of procaine and structurally similar depressants of excitation emphasizes their interaction with membrane calcium[1]. Procaine, it is suggested, replaces calcium at membrane anionic sites and this inhibits the influence of excitable stimuli on processes leading to sodium influx. The hypothesis is based, in part, on the assumed role of calcium in excitation, for the release of this cation is widely viewed as the first important step in membrane depolarization[2]. Furthermore, high concentrations of external calcium oppose the action of procaine on frog motoneurones[3] and lobster giant axons[1]. Evidence that procaine or other local anaesthetics actually increase the mobility of membrane calcium has not yet been reported. I have investigated the interaction between procaine and calcium in nerve and muscle and the question of whether procaine causes the calcium to be released from these tissues.

Sciatic nerves isolated from frogs (*Rana pipiens*) were desheathed and placed in a buffered Ringer solution (*p*H 7·2) of a composition already described[4]. Frog sartorius muscles were isolated and immersed in the same type of Ringer solution. After equilibration in normal Ringer solution at 22°–24° C, tissues were immersed for 4–8 h in Ringer solution (5° C) labelled with 10 μc./ml. of calcium-45. The tissues were then rinsed with 20 ml. of non-radioactive Ringer solution, and a single nerve or

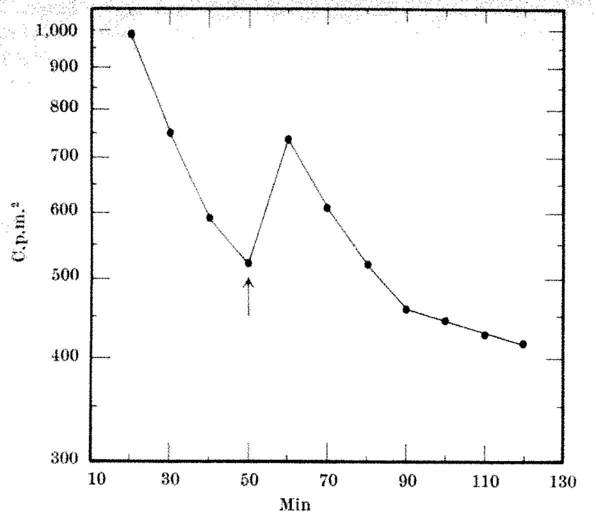

Fig. 1. Effect of 20 mM procaine on the time course of the rate of efflux of calcium-45 from isolated desheathed nerve. Procaine added at arrow. Each point is average of six nerves. Calcium-free Ringer solution used throughout.

muscle was placed in a chamber containing 2 ml. of calcium-free Ringer solution. After 10 min, the 2 ml. of collection fluid was placed in a scintillation vial and replaced by fresh calcium-free solution; this procedure was repeated every 10 min for the duration of the wash-out period, which was carried out at 22°–24° C. At the end of the wash-out, tissues were ashed and dissolved in acid. To each 2 ml. of collection fluid or 2 ml. of acid-dissolved ash was added 20 ml. of scintillation fluor. The radioactivity of each sample was measured in a liquid scintillation spectrometer, the efficiency for calcium-45 being 80 per cent. Two types of curves were plotted from the data: (*a*) a rate curve which describes the time course of the rate of calcium-45 efflux; and (*b*) a rate coefficient curve which is the percentage of the average tissue radioactivity during the time of collection that has emerged each minute during the collection interval.

The calcium-45 wash-out curve from nerve or muscle consists of an initial fast and a later slow component, and treatment with the local anaesthetic began during the slow phase. The slowly emerging calcium-45 probably derives from axons or muscle fibres but the specific locus of the cellular compartment remains uncertain. On the basis of results discussed below, we can at least conclude that the compartment(s) is readily accessible to the extracellular environment and is readily exchangeable with extracellular calcium, suggesting a membrane locus.

About 7 to 10 mM procaine is required to produce a measurable and consistent release of calcium-45 from the desheathed nerve, and 20 mM gives the maximum effect (Fig. 1). The maximum release occurs within the first 10 min of collection after procaine has been added to the nerve bath; this is followed by a rapid return of efflux to a rate measured in the absence of procaine. At 7 mmolar, procaine causes complete depression of the α-A fibre spike of desheathed nerve within 5 min (in normal or calcium free Ringer solution). Thus the calcium-releasing action requires relatively high anaesthetic concentrations. This may indicate that the calcium-releasing effect is not causally related to the anaesthetic effect of procaine or, as is more likely, that the amount of calcium-45 released is a very small fraction of the total emerging from the tissue.

If non-radioactive calcium (calcium-40) is added to the calcium-free nerve bath during the slow phase of calcium-45 efflux, a rapid and transient release of calcium-45 is produced. It is known that procaine depresses this so-called self-exchange reaction in frog skeletal muscle[5].

In frog desheathed nerve, 20 mM procaine depresses the influence of 5 mM calcium-40 on calcium-45 efflux. But this depression can be quantitatively accounted for by the calcium-releasing action of procaine (Fig. 2). This suggests that the calcium released by procaine and by calcium itself comes from the same cellular site, probably the membrane. Of even greater interest is the effect of 5 mM procaine on the calcium-releasing action of calcium-40. As Fig. 2 shows, this concentration of procaine has no effect on the rate of calcium-45 efflux, but it does enormously potentiate the exchange between calcium-45 and calcium-40. Rather than competing with extracellular calcium-40 for tissue calcium-45, procaine apparently weakens the association between calcium-45 and tissue binding sites.

In skeletal muscle, about 50 mM procaine is required to produce a consistent increase in the rate of calcium-45 efflux (Fig. 3), a concentration which causes complete loss of excitability within 3 min. The lower sensitivity of muscle to the calcium-releasing action of procaine may be related to the lower sensitivity of muscle (compared with nerve) to the anaesthetizing action of procaine. Of particular interest in Fig. 3 is the comparison between the action of procaine and the more potent local anaesthetic, tetracaine. At one-tenth of the concentration of procaine, tetracaine produces almost twice the increase in the rate of calcium efflux, and the effect is more enduring.

These results support the hypothesis that the action of local anaesthetics of the procaine type on excitable membranes is causally related to displacement of membrane calcium. We have recently tested the effect of 10^{-5} M tetrodotoxin on the desheathed nerve and found no influence of this maximally depressant concentration on the rate of calcium-45 efflux. This suggests some degree of specificity of the procaine type of local anaesthetic for the calcium-releasing mechanism. On the other hand, it seems paradoxical that procaine has an effect on calcium efflux qualitatively similar to that of other agents, such as calcium chelators[6], which lower excitability thresholds

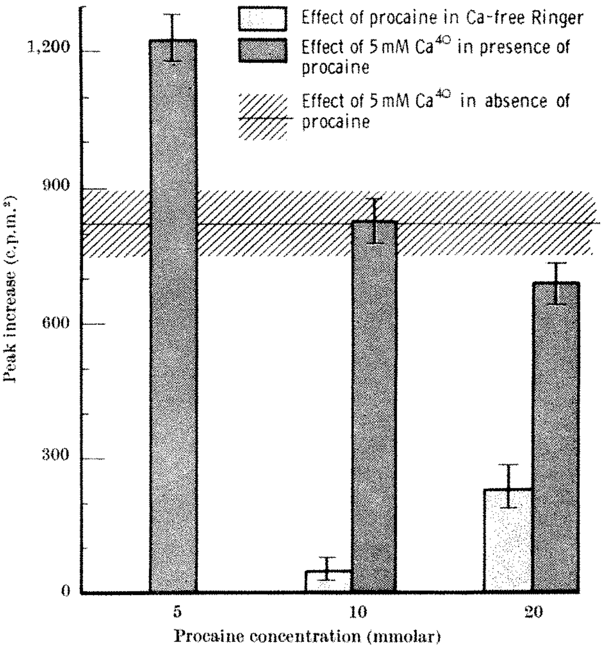

Fig. 2. Effect of various concentrations of procaine on release of calcium-45 from isolated desheathed nerve and on the exchange between calcium-45 and calcium-40. Each vertical bar represents an average of 6 nerves ± *S.D.* Peak increase is calculated as the difference between the maximum amount of calcium-45 released by procaine or calcium-40 and the amount of calcium-45 measured just before treatment. Procaine added at 50 min and calcium-40 added at 90 min from start of washout. Horizontal bar represents average peak amount (six nerves) of calcium-45 released by 5 mM calcium-40 in the absence of procaine. Note marked potentiation of effect of calcium-40 by 5 mM procaine.

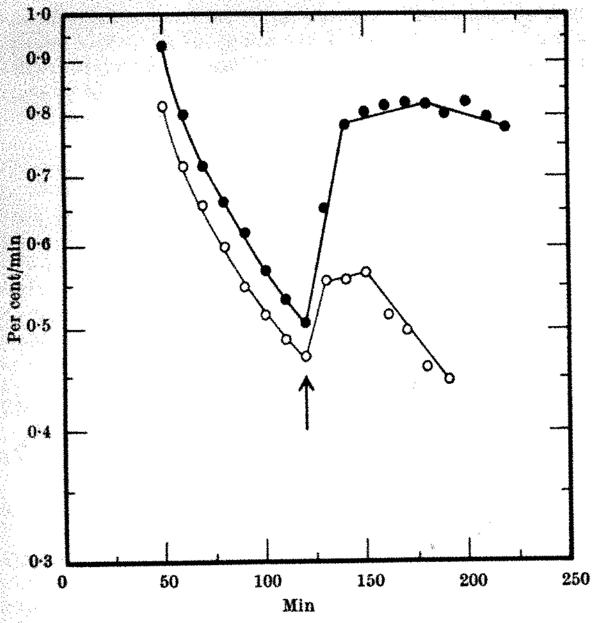

Fig. 3. Effect of procaine and tetracaine on the rate coefficient of calcium-45 release from isolated sartorius muscle. Each point is average of 6 muscles. Calcium-free Ringer solution used throughout. ●, 5 mmolar tetracaine; ○, 50 mmolar procaine.

and produce spontaneous impulses. Furthermore, procaine antagonizes the effects of these threshold-lowering agents at concentrations much less than those needed to release calcium[7]. Clearly there is much to learn about the roles of calcium in excitation and about the cellular localization of the different calcium-binding sites involved in excitation. Perhaps further investigation of the interaction between procaine and calcium will contribute to the solution of these problems.

Photoinhibitory Function of the Dorsal Ocelli in the Phototactic Reaction of the Migratory Locust *Locusta migratoria* L.

AT least two physiological functions have been ascribed to the dorsal ocelli of locusts and insects in general. First, in response to light intensity they regulate the speed of movement (photokinesis)[1] and the threshold for the initiation of certain activities[2]; and second, coupled with the complex eyes, they are in some unknown way involved in angular orientation, both in the phototactic[1,3,4] and in the dorsal light reaction[5,6].

The following facts have led to a new hypothesis of co-operation between the three dorsal ocelli and the complex eyes in the control of the phototaxis of locusts. Locusts and grasshoppers which react phototactically can respond to changing light intensity in two ways: thus the strength of the phototactic turning tendency can either increase or decrease with increasing luminous intensity (that is, direct and inversely proportional reaction types). The discovery of the inversely proportional reaction, in which the strength of the response wanes with increasing intensity of stimulus, suggested an inhibitory mechanism which may be switched on and off[7]. In view of the electrophysiological evidence for the photoinhibition of the spike frequency of the ocellar nerve[8] and the observation that the menotactic angles of locusts can increase as a result of the occlusion of the ocelli[1], it seemed that the dorsal ocelli supply the input to this inhibitory mechanism[9]. To test this hypothesis we have investigated the relationship, in laboratory reared migratory locusts, between the occlusion of the ocelli and the relative strength of the phototactic turning tendency which is dependent on light intensity.

Two different methods of quantifying the strength of the phototactic turning tendency were employed—the geo-phototactic compromise experiment and the menotactic angle experiment. The equipment for the compromise experiment consisted of an inclined plane 1 m square with a slope of 30° ; the plane was illuminated from the side with a horizontal beam of light (Fig. 1). The light source, a Prado slide projector, 380 cm from the centre of the platform was visible as a disk of light with a luminous intensity of 200 stilb (full intensity) and subtended an angle of approximately 1°.

Locusts showing negative geotaxis and positive phototaxis which were placed head upwards in the centre of this plane assumed a compromise position between negative geotaxis and positive phototaxis. The stronger the turning tendency of the locust toward the light source, the greater the angle of compromise (α) will be. Locusts which show negative phototaxis behave similarly but turn away from the light source.

In testing the relative strength of the phototactic turning tendency, each animal was placed on the inclined plane and was allowed to orientate itself. The angle of the direction of the path of movement was then measured. Each individual tested was exposed five times in alternating sequence to each of the four following conditions: (1) ocelli intact and the light source at full intensity; (2) same as in (1) but with the light source reduced to 1/200 full intensity with a neutral grey filter; (3) all three ocelli occluded with opaque black shellac and the light source at full intensity; (4) same as in (3) but with the light source reduced to 1/200 full intensity.

Before the experiments were begun the reaction types of the test animals were determined and fourteen individuals of each type were selected for the experiments. The reaction was again checked at the conclusion of the

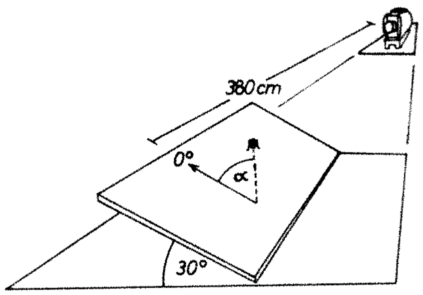

Fig. 1. Apparatus for geo-phototactic compromise orientation. The angle α represents the measurement of the relative strength of the phototactic turning tendency.

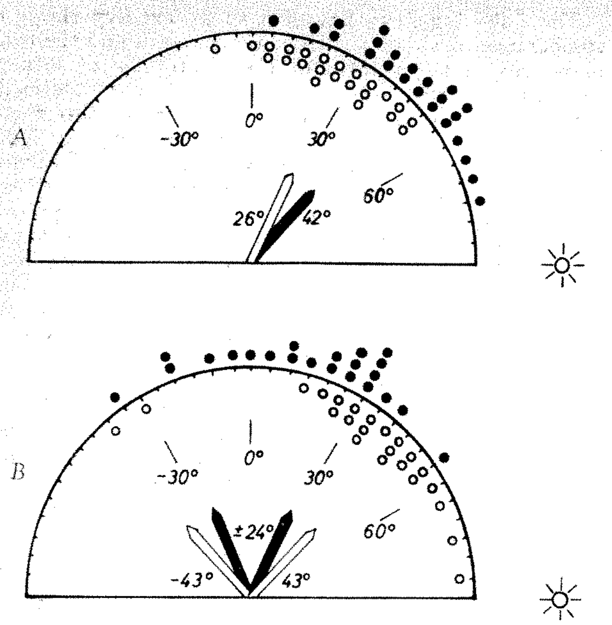

Fig. 2. Effects of changing light intensity on the relative strength of the phototactic turning tendency of inversely proportional reacting *Locusta migratoria* during the geo-phototactic compromise orientation. Each point represents three trials of a total of seventy runs executed by fourteen individuals. ●, Intensity of 200 stilb; ○, intensity of 1 stilb. The arrows indicate the mean angular deviation from 0° for both intensities; in (*B*) this was calculated irrespective of sign. (*A*) represents the results of tests in which the ocelli were intact, (*B*) represents tests in which the ocelli were occluded.

experiments to determine whether there had been a change from one to the other reaction type during the experiments.

The results show that the directly proportional reacting locusts maintained their reaction type after occlusion of the dorsal ocelli. The inversely proportional reacting individuals, however, reacted in a directly proportional manner when the ocelli were eliminated (Fig. 2). Thus the original photoinhibition of the phototactic turning tendency (Fig. 2*A*) was no longer evident (Fig. 2*B*). Both the photoinhibitory effect (inversely proportional reaction) before, and the photoexcitational effect (directly proportional reaction) after, occlusion were found to be statistically significant. (Fig. 2*A*, t test for mean angles, $P < 1$ per cent. Fig. 2*B*, χ^2 test, H_o: number of scores above and below the common mean angle (32·62°) are the same for both intensities, $P < 1$ per cent.) In control experiments in which animals were tested with clear shellac on the ocelli, the angular orientation of the inversely proportional reacting individuals was not affected.

The theory of the menotaxis of Jander[10] offered a second means of testing the relative strength of the phototactic turning tendency. In contrast to the first method in which the orientation arises as a balance between the opposing geotactic and phototactic turning tendencies, this method involves only the phototactic response. According to the menotactic theory the angular deviations of orientation pathways from the phototaxis (menotactic angles) are dependent on the strength of the phototactic turning tendency and must become smaller as this increases.

In this experiment, the same fourteen individuals from the previous test which reacted inversely proportionally were placed on a level platform to one side of which was a horizontal light source; the individuals were allowed to move towards the light. The light source was the same as that used in the first experiments. The parameter which was measured was the angular deviation of the direction of the positive phototactic orientation from the route which was aimed directly at the light source. Most individuals were tested five times in alternating sequence under the two light intensities with the ocelli either open or covered with black shellac as in the first experiment. During this experiment, several individuals with occluded ocelli walked in circles instead of executing directional orientations, indicating a breakdown in the orientation mechanism.

On decreasing the intensity of the light source, the variance of the menotactic angle decreased in locusts with intact ocelli (Fig. 3*A*); thus the strength of their phototactic turning tendency increased. The opposite results were, however, observed in the same experiments in which the ocelli were occluded; the strength of the phototactic turning tendency decreased when the intensity was lowered (Fig. 3*B*). The variances in the angular distribution in both experiments were significantly different under the two light intensities (F test, $P < 1$ per cent). Because essentially the same effect was observed using both this method (Fig. 3) and the first method (Fig. 2), we concluded that the ocellar nerve exerts a photoinhibitory (skotoexcitory) effect on the strength of the phototactic turning tendency of inversely proportional reacting migratory locusts.

Thus, in this behaviour, the intensity-dependent control of the phototactic turning tendency exerted by the ocelli is complementary to the corresponding control exerted by the complex eyes: photoinhibition through the ocelli, photoexcitation through the complex eyes. The results of this co-operation can be described as a form of central light intensity adaptation.

A possible biological meaning for this interaction is suggested by observations which were made during

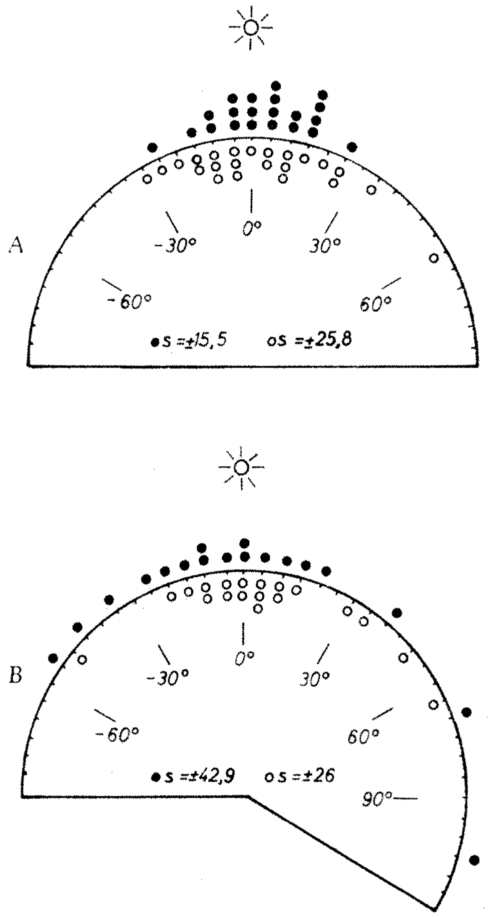

Fig. 3. Effects of changing light intensity on the variance of the menotactic angle of inversely proportional reacting *Locusta migratoria* during phototactic orientation. Each point represents three runs from a total of seventy runs in (*A*) and 67 and 59 in (*B*) carried out by fourteen animals. ○, Intensity of 200 stilb; ●, intensity of 1 stilb. In (*A*) ocelli were intact. in (*B*) they were occluded.

the second experiment. In conditions of weak intensity the ability of several individuals to orientate themselves with occluded ocelli broke down and they began to circle instead of progressing towards the light source. This was probably because the phototactic turning tendency without the darkness stimulation of the ocelli had become too weak. This effect was never observed in locusts with intact ocelli or in the control animals.

Electroencephalogram Potentials evoked by Accelerated Visual Motion

CHANGES in the brightness and the spatial or temporal pattern of visual stimuli evoke small correlated changes in the electroencephalogram (EEG) potentials recorded from the occipital scalp and can be revealed by averaging the responses to repeated stimuli[1-5]. We have investigated the effects of changes in the velocity of patterned stimuli and have found what seem to be analogous evoked responses to acceleration of the retinal image.

It is well known that the perceived velocity of a moving figure is increased in the vicinity of a stationary reference point. Our first experiment was made to discover (*a*) whether any evoked potentials could be detected when a stationary visual stimulus was set in motion; (*b*) whether the proximity of a reference line affected the magnitude or form of any response detected.

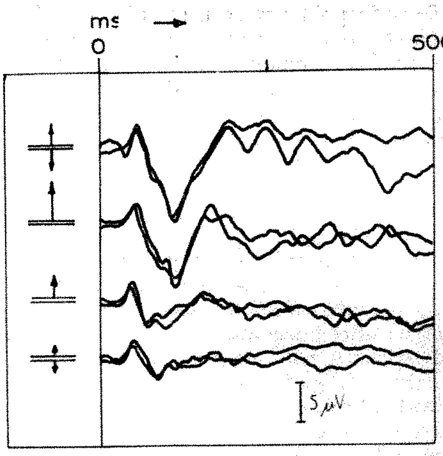

Fig. 2. Comparison of EPs for symmetrical and asymmetrical displacements giving relative velocities of 4 cm/s (upper) and 2 cm/s (lower).

The stimulus first used was a single horizontal line of light 7 cm long generated by an oscilloscope with a 100 kHz timebase and a normal green phosphor. The line was displaced vertically by a "ramp" function (Fig. 1*A*) so that it returned to start and repeated its course every 2 s. A second beam could be used to provide an adjustable stationary reference line on the same screen, parallel to the first. Alternatively, a front-silvered mirror parallel to the line direction and normal to the screen could enable an image of the stimulus line, moving in the opposite direction, to be added to the field of view at a varying initial distance from the first line. The viewing distance was 50 cm, and a faintly lit fixation point was optically superimposed.

The electrode placements used are shown in Fig. 1, which also shows some typical results, each obtained by averaging 100 responses on a Mnemotron *CAT* 400 computer. Fig. 1*B* shows that significant responses with a negative-peak latency of about 60 ms were obtained when an isolated stimulus line moved from rest with a velocity of 2 cm/s, and that the presence of a reference line enhanced the response, by an amount inversely related to the initial separation of the two lines (Fig. 1*C* and *D*). As a check of fixation, eye movements were monitored by electrical recording of trans-orbital potentials, and it was verified that any transient movements occurring were too small to contribute significantly to the average evoked potential.

As a further check, a symmetrical display (two lines diverging) was provided with the help of the mirror, so that fixation was more easily maintained. The results, shown in Fig. 2, seem to discount the likelihood that eye movements were responsible for the EPs. There is a clear similarity in magnitude and general form between the main components of the response to a line moving with a given velocity relative to a fixed line, and the response to two lines moving with equal and opposite velocities of half that amount.

It seemed possible that part of the evoked response might be an off effect caused by the removal of light from the foveal area when the line was displaced. Accordingly,

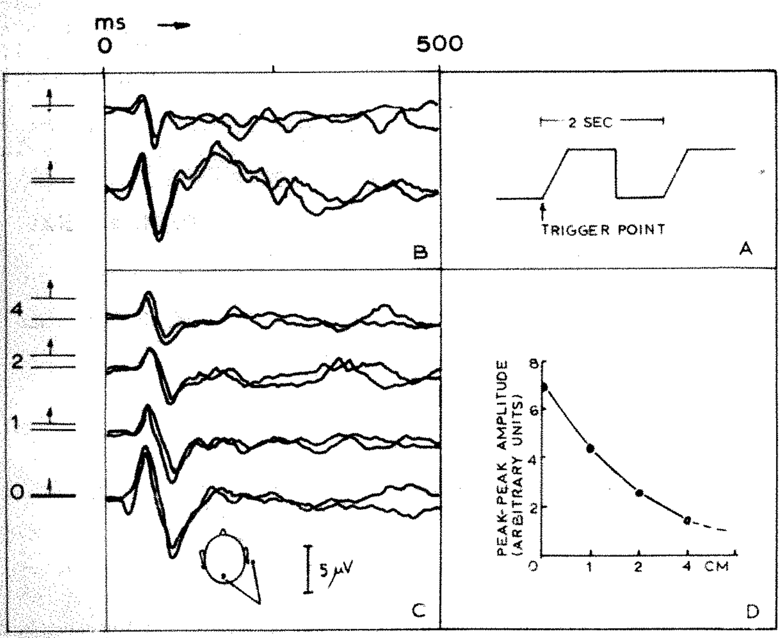

Fig. 1. *A*, Vertical deflecting waveform. *B*, Comparison of EPs to velocity step of 2 cm/s without reference line (upper) and with reference line (lower). *C* and *D*, Effects of distance of reference line (measured in cm) from starting point of moving line.

different fixation points were used, above and below the initial position of the accelerated line, so that motion of the line would in one case increase the total light on the fovea, and in the other case decrease it.

Although the EP drops off rapidly with eccentricity of fixation, it can be seen from Fig. 3 that there is no consistent asymmetry between the EPs with fixation above and below the rest position, such as would be expected if the change in total foveal illumination were responsible for the EP.

Partly in order to reduce any possible on or off effects as the moving line left the fovea, the spatial extent of the moving stimulus was increased by converting it into a raster of parallel horizontal lines, which was deflected up and down as a whole by the slow ramp waveform. The main effect (Fig. 4*A*) was a considerable increase in the amplitude of response. In order to minimize possible on or off responses as the individual raster lines appeared or disappeared at the edge of the field, the CRT face was masked by a sheet of photographic film having a circular aperture 5 cm in diameter with a blurred edge, but no significant change was produced by this.

The strong effects of reducing the spacing—and thus increasing the number—of the moving lines can be seen from Fig. 4*A*. Perhaps most striking is the finding (Fig. 4*B*) that with a many-line raster the introduction (by use of the mirror) of a second raster moving in the opposite direction now brings about an increase of only 30 per cent in EP.

With the help of a Dove prism, the effective orientation of the display (now viewed monocularly) was changed so that motion occurred in one of eight different directions. The ramp waveform was replaced by a sawtooth waveform with the gradients adjusted to be equal in both directions, so that the velocity of stimulus motion was simply reversed every 2 s. Electronic switching was used to gate the responses to alternate reversals into different channels of the *CAT* computer. The results showed no significant dependence of the evoked potential on the direction of stimulus motion.

The EPs recorded in these experiments seem clearly related to acceleration of a central portion of the retinal image. Their magnitude reflects both the change in velocity and the number, but not the direction, of accelerated contours.

They might therefore be parsimoniously interpreted as non-vectorial signs of the disturbance of the retinal population by the displacement of contours from stimulated to unstimulated areas; but it also appears from Figs. 1 and 2 that this disturbance is greatly increased (at least with small numbers of moving lines) by the proximity of other lines to serve as landmarks. The nature of the technique prevented the recording of signals indicative of steady velocity, so it remains doubtful whether these EPs reflect the activity of velocity-sensitive units in the visual cortex. It seems likely, however, that they may have a similar origin to the EPs recorded by Gaarder *et al.*[6] following saccadic eye movement, and to the EPs for pattern reversal recently described[7,8] which can be regarded as a limiting case for infinite image velocity.

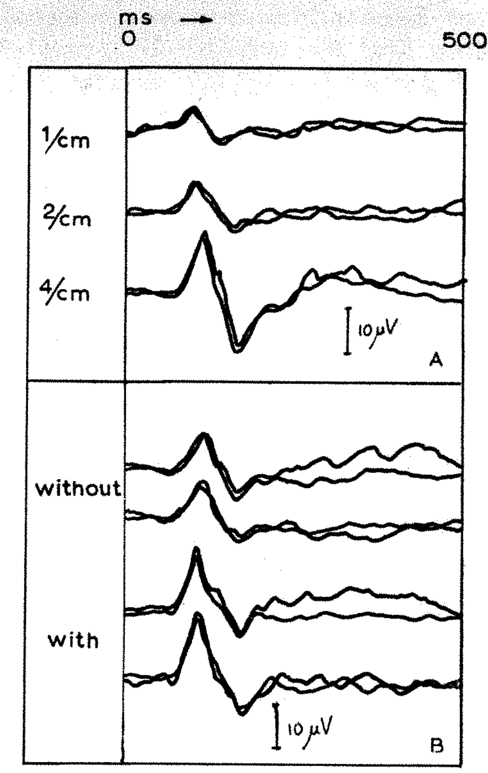

Fig. 4. *A*, Effects of increasing number of moving lines per cm. *B*, Effects of adding mirror image of moving raster.

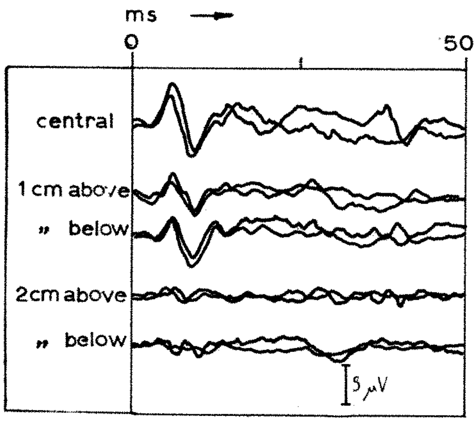

Fig. 3. Effects of off-centre fixation.

This preliminary study obviously raises a number of questions, which require a more flexible method of stimulation for their investigation. Some of these are suggested by the similarity between the present EPs and those evoked by stationary patterns[2-5]. An improved stimulator using continuously movable "visual noise" patterns has been constructed, and results obtained with it will be described elsewhere.

Effect of Excess Magnesium on Vagal Inhibition and Acetylcholine Sensitivity of the Mammalian Heart *in situ* and *in vitro*

It is known that an excess of magnesium ions blocks synaptic transmission through the ganglia of the sympathetic nervous system of mammals[1,2]. It is also accepted that peripheral parasympathetic pathways contain relay synapses at or near the target organ. The pharmacological properties of the junction between pre and post-ganglionic neurones in the parasympathetic system are believed to be similar to those in the ganglia of the orthosympathetic system. Stanbury[2], however, failed to observe blockade of the inhibitory effect of the vagus in cats treated with sufficient magnesium to block transmission in orthosympathetic ganglia.

We became interested in this problem during two experiments on the effect of intravenous administration of magnesium sulphate to human subjects[3]. In these experiments, sufficient magnesium was administered to cause complete paralysis of most skeletal muscles, but the two subjects remained conscious, and their EEG was unaffected. The only sign that could perhaps indicate that the central nervous system was depressed by the magnesium was the disappearance of (respiratory) sinus arrhythmia, which was noticed in both subjects. If the inhibitory effect of the vagus was transmitted normally in these subjects, the reflex modulation of the heart beat must have been blocked at a site "upstream" of the vagus, presumably in the central nervous system.

Since our report[3] has appeared, Toda and West[4] have shown that magnesium diminishes the negative chronotropic effect of vagal stimulation in isolated atria of rabbits. They used a higher concentration of magnesium on the isolated tissue than that which was effective in our human subjects. To determine whether the same dose of magnesium that paralyses skeletal muscle will also block vagal inhibition of the heart *in situ*, we carried out experiments with twelve unanaesthetized high spinal cats. One or both vagi were exposed in the neck and equipped with paired wire electrodes. Ten second trains of 0·5 ms shocks were delivered to the vagus at 1 min intervals. The intensity of the stimuli was kept above the maximum, but various frequencies were tried in most experiments. The arterial blood pressure and a lead II electrocardiogram (ECG) were recorded. In some experiments the isometric contractile force of the anterior tibial muscle, stimulated through its motor nerve, was also measured. The concentration of magnesium and calcium in plasma was measured in arterial blood samples as described earlier[5].

It is clear from Fig. 1 that during the infusion of magnesium chloride the effectiveness of vagal inhibition diminished. Partial relief was achieved by the injection of a small amount of calcium chloride. As with skeletal muscle, transmission of stimuli of low frequency was depressed earlier, and recovered later, than stimulation at a high frequency.

With the plasma magnesium elevated, high frequency stimulation of the vagus caused a partial block in atrio-ventricular conduction. Because of this, the ventricular beat was suppressed and the drop of blood pressure was almost as severe as in the control period, although the atrial frequency was much less affected by the vagus during infusion of magnesium than in the control state.

Similar results were obtained in every experiment. The effectiveness of vagal inhibition varies from cat to cat. On the whole, the magnesium block of vagal inhibition was more severe in animals where the vagal effect was weak.

Block of vagal inhibition could be a result of diminished acetylcholine output from presynaptic terminals, or of a decreased effect of the acetylcholine itself. A distinction between these two alternatives was possible by experiments on isolated perfused hearts. The heart of an anaesthetized rabbit was excised with the vagus nerve attached, and the coronary bed perfused with a constant-flow pump through the aorta. The Krebs–Ringer solution contained: Na^+ : 145 mequiv./l.; K^+ : 5·9 mequiv./l.; Ca^{++} : 5·0 mequiv./l.; Mg^{++} : 2·3 mequiv./l. ; Cl^- : 131 mequiv./l.; HCO_3^-: 24·0 mequiv./l.; SO_4^{--}: 2·3 mequiv./l.; $H_2PO_4^-$: 1·2 mequiv./l. Perfusion fluid with a high concentration of magnesium was prepared by adding isotonic (0·2 equiv./l.) magnesium chloride to the Krebs solution to bring the total magnesium concentration to 17 mequiv./l. Perfusion fluid with a high concentration of calcium contained 10 mequiv./l. calcium. The ECG was recorded differentially between right atrium and right ventricle using fine stainless steel hooks attached to the heart wall. The heart was immersed in Krebs solution; the temperature was kept at 37° C. Acetylcholine chloride was injected through a three-way tap close to the heart in volumes of 0·05 or 0·1 ml.

As shown on Fig. 2, the basal heart rate was slow during perfusion with Krebs solution containing an excess of magnesium but, relative to the basal rate, the effectiveness of vagal inhibition decreased. In contrast, injected acetylcholine caused a more pronounced inhibition of the heart perfused with Krebs solution containing a high concentration of magnesium than in the control state. Calcium, in the concentration used, enhanced the effect of vagal stimulation without much change in the effectiveness of injected acetylcholine.

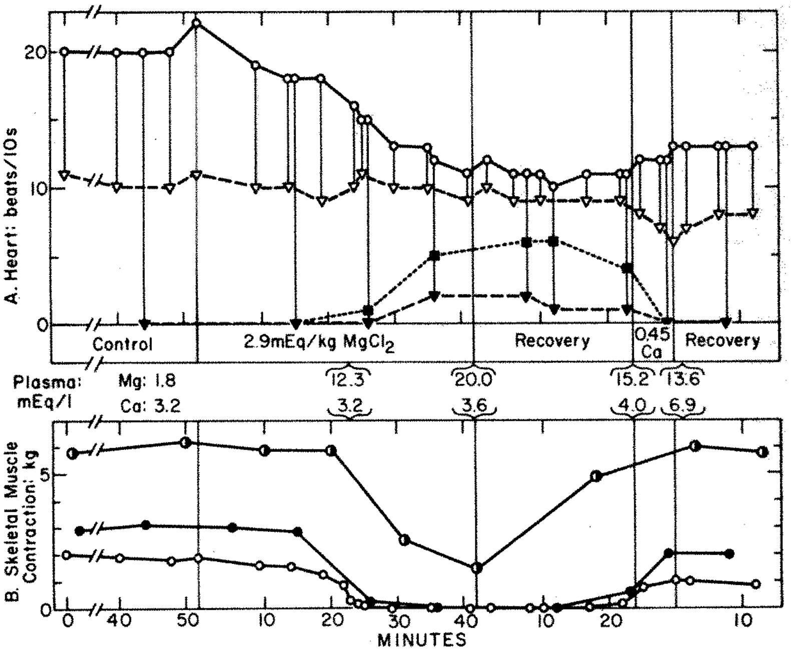

Fig. 1. Effect of intravenous infusion of 2·9 mequiv./kg body weight of magnesium chloride and 0·45 mequiv./kg of calcium chloride on heart rate and vagal inhibition of the heart (*A*); concentration of magnesium and calcium in plasma; and contractile force of anterior tibial muscle, stimulated via its motor nerve (*B*). *A*, Basal ventricular rate, counted in 10 s immediately before stimulation of vagus (○—○); ventricular rate during 10 s stimulation of vagus at 2/s (▽—▽); and at 20/s (▼—▼), atrial rate, when A-V conduction block occurred (■ . . . ■). *B*, Maximal force of contraction of muscle stimulated at 2/s (○—○); 20/s (●—●); and 200/s (◑—◑). During and after the infusion of magnesium tetanic tension was not well maintained, but only peak tension is shown on the chart.

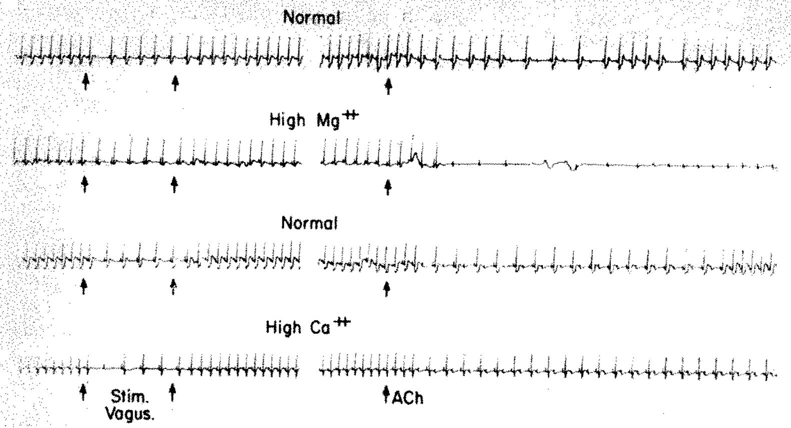

Fig. 2. The effect of stimulating the vagus at 25/s for 5 s, and of the injection of 2·5 μg of acetylcholine chloride, on an isolated rabbit heart perfused with Krebs solution; with solution containing 17 mequiv./l. of magnesium; and with solution containing 10 mequiv./l. of calcium.

It is clear that the partial atrio-ventricular conduction block, seen with vagal stimulation of a high frequency in the intact animal, is caused by the increased sensitivity of the conducting tissue of the heart to acetylcholine in the presence of excess magnesium. Infusion of calcium always caused an increase of the basal rhythm of the heart *in situ* (see Fig. 1*A*). The reason is not clear, but it could be caused by the release of adrenaline or noradrenaline. On pacemaker tissue which has been isolated, calcium has a negative chronotropic effect[4].

In conclusion, a rise in the magnesium content of plasma or perfusion fluid circulating in the coronary bed causes a decreased effectiveness of vagal inhibition. This is probably caused by a decrease in the release of acetylcholine. At the same time the effect of excess magnesium results in the increased sensitivity of the cardiac pacemaker and the atrio-ventricular conductile apparatus to the inhibitory effect of injected acetylcholine.

It is not clear from our observations whether the site of block is at the preganglionic, or the postganglionic terminals, or at both. Toda and West[4], who have studied isolated atria, concluded that magnesium had a blocking effect at both sites.

This work was supported by a grant from the US Public Health Service. We thank Dr M. I. Hilmy, who carried out the magnesium determinations in plasma.

Effect of Methionine Sulphoximine on Memory Transfer

Methionine sulphoximine influences the metabolism in the central nervous system in a number of different ways[1]. It affects the glutamine formation in the brain[2], decreases the incorporation of phosphorus-32 in cytoplasmic ribonucleic acid[3] and decreases the incorporation of methionine labelled with sulphur-35 into the brain proteins[4]. Methionine sulphoximine is an epileptogenic agent[5] and in subconvulsive doses it blocks alimentary conditioned reflexes[6]. Injection of this compound causes pathological changes in the synapses where considerable quantities of the drug are found[7].

In our experiments, methionine sulphoximine was used to study the mechanism of "transfer of memory trace" from one animal to another by means of brain extracts.

White mice were trained to open a transparent door in front of some food pellets, which were identical with those used in normal feeding. A light above the door acted as a conditioning stimulus accompanying the food. The mice were trained three times a day, each session consisting of ten trials with an interval between each trial of 80 s. The conditioning stimulus lasted 10 s and the opening of the door was recorded electrically. Mice were considered to be trained when they gave ten positive responses in a session, that is, they opened the door within the time of the conditioning stimulus and did not open the door more than ten times between trials.

D,L-Methionine sulphoximine, in a dose of 150 mg/kg of body weight, was injected intraperitoneally 20–24 h before the last training session. This dose does not cause convulsions but blocks the conditioned responses in trained donors. The injected trained donors were then tested in the experimental cage. The mice were killed within 1 h of testing and the brains were removed and homogenized in 2 ml. of distilled water. The homogenate was shaken for 4 h, left in the refrigerator at 1°–2° C overnight and centrifuged at 10,000 r.p.m. for 4 h. The supernatant was injected into the peritoneal cavities of the acceptor mice, which were tested in the experimental cage 24 h after the injection. The animals were starved between injection and testing. The number of conditioned reactions in the first testing session was calculated and the results were evaluated by means of rank correlation analysis for dichotomic ranks[8].

Experiments were performed with forty-seven acceptor and forty-seven donor mice, in six groups as shown in Table 1. Injections of extracts from an untrained brain into untrained animals did not improve the animals' response in the testing session, as compared with that of untreated animals ($S=50$, P not significant). Injections of extracts from trained brains increased the number of positive reactions in the first session when this group was compared both with controls without injection ($S=122$, $P<0{\cdot}001$) and with the results from acceptors injected with extracts from untrained brains ($S=73$, $P<0{\cdot}001$).

Injection of the subconvulsive dose of methionine sulphoximine blocks almost completely the alimentary conditioned reflex. The number of conditioned responses decreased from ten positive responses to none. Only for one animal were two conditioned responses recorded. This block could not have been caused by a decrease of appetite, because the animals ate normally at the end of the testing session.

When extracts from brains intoxicated by methionine sulphoximine were injected into the untrained acceptors, it caused a significant increase of positive conditioned responses in the first testing session of ten trials. The rank analysis showed $S=127$ ($P<0{\cdot}001$) when compared with the values from control uninjected animals, and $S=78$ ($P<0{\cdot}001$) when compared with the animals injected with extracts from untrained brains. No difference was noted between the performance of mice injected

Table 1. RESPONSE OF ACCEPTOR MICE TO TESTS IN EXPERIMENTAL CAGE

Donors	Injection of donors	Acceptors	No. of mice	Average No. of positive responses
Trained	—	Untrained	8	6·25
Trained	MSI	Untrained	8	6·38
Untrained	—	Untrained	10	2·70
Untrained	MSI	Untrained	15	0·07
Untrained	MSI	Trained	6	10·00*
Untrained	—	Untrained	16	1·88

MSI, Methionine sulphoximine.

* First session after the injection.

with extracts from brains from trained animals and mice injected with extracts from brains from trained animals treated with methionine sulphoximine ($S=0$, P not significant).

Injection of methionine sulphoximine into untrained animals caused no apparent changes of behaviour in normal animal house conditions. Motility was unchanged, there were no convulsions and no change of appetite was noticed. When extracts of the brains of these animals were injected into the untrained mice, three of the fifteen animals died; of the twelve remaining, only one was able to find the food in the first experimental session. The others did not find their way to the food and so the elaboration of the conditioned reflex could not be started. These mice were retested at weekly intervals. Four weeks after the injection, nine of the twelve mice showed response to training. These mice were then trained for positive conditioned responses. The other three mice did not respond during this period.

The six control mice were trained and then injected with extracts from the brains of untrained mice treated with methionine sulphoximine. Injection of this extract had no effect on the formed conditioned reflex. The performance of these six mice was not changed.

Methionine sulphoximine in subconvulsive doses blocks the alimentary conditioned reflex, but it does not disturb the "inter-animal memory transfer" mechanism. The substance responsible for the influencing of the higher nervous activity of acceptor mice is therefore not damaged by the methionine sulphoximine.

RNA (ref. 9) or small proteins[10] are thought to be responsible for memory transfer, but these experiments throw no light on the chemical nature of the phenomenon because of the complex effects of methionine sulphoximine on metabolism.

Injection of extracts from brains of untrained donors treated with methionine sulphoximine has a detrimental effect on the higher nervous activity of the acceptor animals. If this agent, responsible for blocking the ability to be trained, is injected into the trained animal, it has no effect. It is not formed if the donor mouse is trained first. This implies that this substance enters the chain of events leading to the formation of normal memory trace and is able to block it. This can only occur in the situation where the memory trace is not already formed. There is therefore some kind of competition between the formation of the normal memory trace and activity of the agent formed in the untrained brain under the influence of methionine sulphoximine.

The factor causing the deterioration of the higher nervous activity of the acceptor mice is probably not methionine sulphoximine itself, because this factor is, in contrast to the compound, ineffective when the acceptor is pretrained before the injection.

We thank D. E. Laryea, S. D. Foli and Mrs M. Reinišová for technical assistance and D. M. Mobbs for linguistic help.

BIOLOGY

Pre-gravid Phase of Ovarian Development in *Aedes detritus* Haliday

IN *Aedes detritus* (Diptera, Culicidae) Haliday, complete ovarian development to the mature egg state does not always occur after blood feeding. A second blood meal, however, was found to result in complete oogenesis. The occasional need for two blood meals for egg production has been noted in a few tropical mosquitoes[1-5], but has not been reported in any Palaearctic species.

Ae. detritus overwinters in its immature stages. In the Poole area of Dorset, where the investigations reported here were undertaken, the adult biting season was from May to November. A proportion of hungry females which was caught each month in human bait catches was allowed to engorge on the author in the laboratory. Batches of five to ten of these individuals fed on blood were held in paper lined plastic tubes and supplied daily with a wad of cotton wool soaked in water. They were kept outside the laboratory in normal climatic conditions, except that they were protected from direct sunlight and rain. They were examined daily, and 3 days after they appeared to have digested all their blood meal they were dissected and the ovaries classified according to their degree of ovarian development[6]. Any mosquitoes which died within this period were dissected, and if all blood had been digested they were included in the results.

Results in Table 1 show that, whereas all 350 adults fed and dissected from July to September developed fully mature ovaries after one blood meal, a proportion of those caught and fed at the beginning and end of the adult biting season failed to undergo complete ovarian development. These adults are referred to as pre-gravids. The degree of ovarian development after a blood meal is different from that observed in *Anopheles gambiae* Giles and *A. funestus* Giles. In these species, because the ovaries only proceed to stage II, all pre-gravids can be reliably separated from gravid adults without dissection[1,2]. In *Ae. detritus* there was no clear distinction in the external appearance of the two groups, except in those in which ovarian development had not gone further than stage III*b*. Pre-gravids, however, could, with the exception of the few with the ovaries in stage II*b*, be distinguished from unfed adults. It is apparent that at certain times of the year, some of the biting population require two blood meals for completion of the first gonotrophic cycle. It follows that adults at bait will, at least at certain times of the year, form three distinct age groups: (*a*) nulliparous adults with undeveloped ovaries feeding for the first time; (*b*) nulliparous adults with partially developed ovaries taking a second blood meal; and (*c*) parous adults with undeveloped ovaries returning for further feeds. It should be possible to distinguish most of those in the second group from the others, and thirty-seven such pre-gravids were recognized in bait catches. When these were given a blood meal, ovaries developed completely. A mean fertilization rate of 94·7 per cent was recorded in those caught at bait (during months in which pre-gravids were in evidence) which underwent complete ovarian development after one blood meal. In pre-gravids the fertilization rate was 84·8 per cent. The slightly but significantly ($P<0{\cdot}01$) higher fertilization

Table 1. OVARIAN DEVELOPMENT IN *Aedes detritus* AFTER A BLOOD MEAL

Month	Ovarian stages II*b*	III*a*-III*b*	IV*a*	V	Percentage pre-gravids (II–IV)	Percentage fertilization in pre-gravids	Percentage fertilization in older females	Mean monthly temperature ° C
May	0	8	13	58	26·6	85·7	95·5	12·9
June	0	2	2	64	5·9	100	100	14·4
July	0	0	0	98	0	—	95·1	17·1
August	0	0	0	153	0	—	71·1	16·1
September	0	0	0	129	0	—	100	14·9
October	5	12	11	98	22·2	89·3	100	9·5
November	3	25	31	109	35·1	81·4	87·3	8·4

rate in older females indicates that some mating of pre-gravids occurs. In the absence of pre-gravids, the fertilization rate in August was only 71·1 per cent, indicating that mating may occur in gravid individuals.

There is no indication of the proportion of *Ae. detritus* that in certain months require two blood meals for completion of the first gonotrophic cycle. Some adults may by-pass the pre-gravid stage. It was impossible to resolve this in the laboratory because none of the fifty and sixty-nine unmated newly emerged adults maintained, respectively, on tap water and 10 per cent cane sugar solution would take a blood meal. In the first group the ovaries remained in stages I*a*–I*b*, while 92·7 and 7·3 per cent of those fed on sugar solutions developed their ovaries to stages II*b* and III*a*, respectively. There was therefore no evidence of autogeny in the population, as was reported from North Africa[7].

It is not fully understood why pre-gravids seem to occur in the population only at certain times of the year, but similar seasonal occurrences have been reported in *A. annularis* Wulp and *A. culicifacies* Giles in India[6]. The proportion of pre-gravids is greater in cooler months so temperature may be involved. Temperature may affect the quantity of food available for the larval population, and poor larval nutrition has been suggested as a reason for the need for two blood meals during the first gonotrophic cycle in certain species[3,8].

Ultrasound in Rodents

During a comparative survey among small mammals, I found that ultrasounds were produced by the young of all species of myomorph rodents studied. Ultrasounds were also associated with aggressive and submissive behaviour in adult laboratory rats and with aggressive behaviour in the adults of several other species[1]. Observations have now shown that ultrasonic pulses are produced by more species and in more situations than were previously mentioned, and these are reported here.

Ultrasounds have now been detected from the young of *Microtus agrestis* (L.) and *Mastomys natalensis* (A. Smith), both myomorph rodents. Measurements of the intensity of pulses as well as high speed tape recordings for later frequency analysis have now been made for the young of eight species of myomorph rodents. The effect has also been observed in five other species.

Two functions for these sounds produced by baby rodents have been suggested by other authors who reported that they were produced in conditions of stress. They suggested that ultrasounds both aid the retrieval of young to the nest by the parent animal[2,3] and inhibit the aggression of the parent animal to what may seem a strange animal outside the nest. The results of the present intensity measurements may be important in this respect.

For most of the species studied, the intensity of the ultrasonic pulses produced when the animals were left alone under the microphone was lower and decreased at an earlier age than that of the pulses produced when the animals were handled. The intensity of pulses produced by mice of the C_3H strain which were left alone decreased from about the fifth to seventh day until the twelfth to fifteenth day, after which no ultrasound was detected in this condition. This decrease in intensity coincides with the period of development of homoiothermy in mice[4]. For a strain of white mouse, E. Noirot and J. D. Pye (personal communication) have found that the intensity of ultrasonic calls decreases sharply on the seventh day, which is about the day that the development of homoiothermy begins. The termination of calling of *Peromyscus*, elicited by cold stress, apparently also coincides with the onset of thermoregulation[5].

The intensity of ultrasonic pulses produced when young C_3H mice were handled decreased sharply from the eleventh day until the thirteenth to eighteenth day, after which it remained at a low level until observations ceased between days 21 and 37. The pulses became more difficult to elicit as the young reached the age when they leave the family group. Noirot[6] has shown that there is a difference in the rate of calling between young mice left alone in the cage and those being retrieved. From the present study it seems as though there are also differences in the frequency patterns of pulses produced in these two conditions.

Meriones shawi females make occasional attacks on their young as they become old enough to fend for themselves, and Rowell[7] has reported similar attacks by hamsters.

The differing curves for the change of intensity in conditions of handling and non-handling may support the previous suggestion that the ultrasound produced by baby rodents has two functions[2,3]. Those pulses produced when the animals are not handled may be elicited by conditions of stress, cold and hunger, and ultimately result in retrieval and therefore restoration of warmth and food. Their intensity decreases with the decreasing dependence of the young on the mother. Those pulses produced when the young are handled may tend to inhibit the aggression of the retrieving adult. These persist at a higher intensity, but eventually decrease as the young become old enough to protect themselves.

It was reported previously that ultrasounds were associated with aggressive and submissive behaviour in laboratory rats, but in mice no ultrasound has been detected at any time during aggressive behaviour although twelve fights between male laboratory mice have been studied and tape recordings have been made of three of these. This may be significant because in mice no clearly defined submissive posture has been observed which compares with that which often ends bouts of fighting in rats. In *Acomys caharinus* (Desmarest) no ultrasound has been detected during aggressive behaviour, but in *Clethrionomys glareolus* Schr. a few low intensity pulses were recorded during fighting. Ultrasonic pulses at about 70 kHz were detected from *Apodemus sylvaticus* (L.) when one animal of a group faced an intruder, and a few pulses were produced during fighting.

In my earlier work[1], ultrasounds were detected from laboratory and wild rats (*Rattus norvegicus*) when a male mounted or attempted to mount a laboratory female rat or another male, and were detected from mice during mounting and sniffing of either sex by males. Observations of mating in laboratory mice, both C_3H and Noirot's impure strain, have shown that pulses at about 70 kHz were always produced during mounting and seemed to be correlated with the pelvic thrusts of the male. Audible sounds, clearly coming from the females, were often heard at the same time, but were not synchronous with the ultrasound. Ultrasound has also been detected during mating in *Clethrionomys glareolus* and *Acomys caharinus*, and in both it seems to be correlated with the pelvic thrusts of the male. The production of ultrasound during mating is thus common to four species of rodents which seem to differ in the production of ultrasound in other situations.

Purely ultrasonic pulses were detected from adult golden hamsters, *Mesocricetus auratus* (Waterhouse), when another hamster, either male or female, was introduced into the cage of a female on heat. Pulses of 22–30 kHz were heard when the resident female nosed the stranger. This occurred both immediately on introduction and also later during the observation if the female on heat had maintained the rigid mating posture for several minutes without being mounted. Female hamsters are usually very aggressive towards intruders, so the ultrasonic signals may indicate willingness to mate.

In *Acomys* ultrasound at about 50 kHz was detected from a lactating female after her litter had been removed from the nest box.

Another situation in which ultrasound is produced has been found in *Apodemus sylvaticus*. Ultrasonic pulses at 70 kHz have been detected as animals emerged from the nest after the cage had been disturbed. When two pairs of animals were separately put into new cages, no ultrasound was detected immediately in either case, but after 3–5 min pulses were heard as the animals moved around their cages and stood upright on their hind legs. They were often detected while juveniles, 2–3 weeks old, were seen out of the nest and running round the cage in which they were born. It seems possible that in this species ultrasound has an exploratory or territorial function.

These observations in addition to those previously reported[1] show that, among myomorph rodents at least, ultrasound probably plays an important part in several different aspects of social behaviour.

I thank Professor D. R. Arthur for providing facilities for this work, which was carried out during the tenure of a Science Research Council studentship, and Dr J. D. Pye for advice and criticism. This research was supported by the Air Force Office of Scientific Research through the European Office of Aerospace Research, OAR, US Air Force, under a contract to Dr Pye.

Growth Lines in the Larvae and Adults of Bivalve Molluscs

THE existence of growth lines on the shells of adult bivalve molluscs is well known, but little attention has been given to the significance of similar features in the larvae, although they appear in illustrations, such as those of Ranson[1].

In adults, growth lines are the outer edges of growth layers within the shell. The cyclic nature of these layers has been studied by Barker[2], who concluded that the five orders of layers represented growth cycles with periods of approximately 6 h, 24 h, 15 days, 6 months and 1 yr. He suggested that the layers result from periodical changes in temperature, salinity, tidal level and other environmental factors.

Larvae of the European oyster *Ostrea edulis*, when grown in the laboratory and when taken from the plankton, show a series of concentric rings on the shell. The rings are of two orders: major rings which seem to correspond in number to the number of days since the larva was released from the parent, and several minor rings between adjacent major rings. This arrangement is like that described by Barker for adult shells, with the larval major and minor rings corresponding, respectively, to the fourth and fifth order rings of the adult. Both the fourth order adult ring and the major larval ring seem therefore to represent a 24 h rhythm. But in the larva, at least, the occurrence of rings does not seem to result from environmental changes. Typical rings were formed in larvae cultured at constant temperature and illumination, without mechanical disturbance. Furthermore, larvae taken from incubating females of the New Zealand species *Ostrea lutaria* Hutton and the Chilean species *O. chilensis* Philippi have growth rings which number twenty or more. It is significant that in both species the period of incubation is much longer than in *O. edulis*, and extends to about 20 days in *O. lataria* according to Hollis[3] and to 5–6 weeks in *O. chilensis* according to Walne[4]. The number of rings in these species also increases with the number of days of larval life, although the larva during incubation is possibly less subject to daily environmental changes than are the pelagic larvae of *O. edulis*. The larval lines may therefore result from an endogenous rhythm rather than an environmental one. If this is so in the larva, it may also be true of at least the daily (fourth order) lines of adult bivalves. Environmental factors may, of course, modify the expression of an endogenous rhythm.

Barker suggested "laboratory growth experiments and ecological investigations in order to test the hypothesis that growth layering reflects environmental periodicities", and I would add that the part played by endogenous rhythms should also be investigated.

Female Copulatory Behaviour in Male and Androgenized Female Rats after Oestrogen/Amine Depletor Treatment

FEMALE sexual behaviour patterns are infrequent in adult castrated male rats unless very large doses of ovarian hormones are given[1,2]. The age at which the rats are castrated is important[3-5]. Male rats castrated later than 10 days of age and treated as adults with oestrogen in combination with progesterone displayed little feminine behaviour, but when castrated 1–5 days after birth the same hormone treatment caused more distinct female mating behaviour. Absence of androgen a short time after birth leads to behavioural feminization of the male rat.

Testosterone propionate administered neonatally to female rats abolished later feminine mating behaviour in the intact female, and oestrogen and progesterone activated sexual receptivity in ovariectomized rats[6-7].

Recent investigations suggest that in the female rat there are monoaminergic pathways which mediate inhibition of female mating behaviour. The oestrous behaviour activated by oestrogen and progesterone in spayed rats was inhibited by increased central nervous concentrations of monoamine[8-10], but amine depletors such as reserpine and tetrabenazine induced oestrous behaviour in rats treated with oestrogen even when there was no progesterone treatment, which is otherwise necessary for a response[11].

This work describes the extent to which female mating behaviour can be activated with oestrogen in combination with amine depletors in male rats castrated as adults, and in female rats treated neonatally with testosterone and spayed as adults.

Sprague–Dawley female and male rats were raised in a controlled temperature (21°–23° C) under reversed day–night illumination (light on 9 p.m.–9 a.m.). This regime was maintained throughout the experiment. The size of each litter was reduced to eight animals on the third or fourth day after delivery. Half the females in each litter were injected when 4 or 5 days old with 1 mg/0·025 ml. of testosterone propionate in olive oil per rat. The remaining females were injected with olive oil only. Castration and ovariectomy were performed at 90–100 days of age and the animals were used in the experiment 3–4 weeks later. The female or male was brought to a selected vigorous intact male (Wistar strain[8]) and tested for female mating behaviour on three or four occasions between 10 a.m. and 6 p.m. Tests for mating behaviour (lordosis reflex) were conducted as described earlier[8,9]. Each animal was offered at least five mounts with a maximum of eight mounts per test. A positive mating response was recorded when a clear cut lordosis reflex was observed on at least two occasions or on the last test. The hormones were dissolved in olive oil. Reserpine ('Serpasil') and tetrabenazine hydrochloric acid ('Nitoman') were diluted with or dissolved in distilled water.

The female mating pattern was not seen in the castrated males after oestradiol benzoate alone although large doses (50 or 100 μg/kg) were given (Table 1). The combination of oestradiol benzoate (25 μg/kg) and progesterone (0·4 mg/animal) elicited a weak response: only two out of twenty animals displayed the lordosis response when mounted by another male. Increasing the doses of oestrogen and progesterone to the maximal dose in the female ovariectomized rat did not lead to any further response in the castrated males. Oestradiol benzoate (25 μg/kg) followed 48 h later by reserpine (1 mg/kg) or tetrabenazine (40 mg/kg) activated an explicit female mating response in 40–50 per cent. The treated males accepted mounting by a normal male and displayed an evident lordosis reflex. No darting activity or ear movements typical of the female in heat were seen.

The gross time relationship between the injection of oestrogen and the ability of the males to respond is shown in Table 2. Reserpine was given at the same time as the oestrogen treatment. Most males which responded did so in tests performed 52–58 h after the hormone/amine depletor treatment and continued to respond 24 h later. The sedative effect of treatment with reserpine was very slight in the 52–58 h and 76–82 h tests. The males moved spontaneously with only a slight decrease in locomotor activity and exploring behaviour. They still had some ptosis.

Females treated with testosterone propionate 4 or 5 days after birth had a decreased ability to respond to oestrogen/progesterone treatment (Table 3, *A* and *B*). The number of females treated with androgen which came into heat after treatment with oestradiol benzoate (10 μg/kg) and progesterone (0·4 mg/animal) was about 50 per cent of that of the controls. This relationship persisted even when a larger dose of the hormones was used (Table 3, *B*) or when progesterone was replaced by one of the amine depletors, reserpine or tetrabenazine (Table 3, *C* and *D*). No qualitative differences were seen between the lordosis response displayed by the controls and the animals treated with androgen.

Table 1. LORDOSIS RESPONSE IN MALE RATS CASTRATED AS ADULTS

Treatment At 0 h	At 48 h	Lordosis response %	No.
OEB 50 μg/kg	Oil only	0	30
OEB 100 μg/kg	Oil only	0	10
OEB 25 μg/kg	Prg (0·4 mg/animal)	10	20
OEB 50 μg/kg	Prg (1·0 mg/animal)	10	21
OEB 25 μg/kg	Reserpine (1·0 mg/kg)	50	24
OEB 25 μg/kg	Tetrabenazine (40·0 mg/kg)	40	10
None	Prg (1·0 mg/animal) and reserpine (1·0 mg/kg)	0	20

OEB, Oestradiol benzoate; Prg, progesterone.

Table 2. LORDOSIS RESPONSE IN MALE RATS CASTRATED AS ADULTS

Treatment	Hours after oestrogen injection	Lordosis response %
OEB (50 μg/kg) and reserpine (3 mg/kg)	28–34	9
	52–58	57
	76–82	48
	Cumulated:	61 ($N=23$)

OEB, Oestradiol benzoate.

Table 3. LORDOSIS RESPONSE IN ANDROGENIZED, OVARIECTOMIZED FEMALES

Treatment		Lordosis response		
At 0 h	At 48 h	Controls %	Treated rats %	Treated as percentage of controls
A, OEB (10 μg/kg)	Prg (0·4 mg/animal)	61 (23)	28 (21)	46
B, OEB (25 μg/kg)	Prg (2·0 mg/animal)	80 (18)	40 (15)	50
C, OEB (10 μg/kg)	Tetrabenazine (40 mg/kg)	72 (18)	36 (14)	50
D, OEB (10 μg/kg)	Reserpine (1 mg/kg)	77 (13)	33 (15)	43
E, OEB (10 μg/kg)	Reserpine (1 mg/kg) and Prg (0·4 mg/animal)	69 (16)	42 (12)	61

OEB, Oestradiol benzoate; Prg, progesterone.

Numbers in parentheses are the numbers of animals tested. Treated rats each received 1·0 mg of testosterone propionate in olive oil at 5 days of age. Controls had the same volume of oil (0·025 ml.).

Data from previous experiments with female rats suggest the existence of central nervous monoaminergic pathways which mediate inhibition of mating behaviour. These observations show that it is possible to induce female copulatory pattern in adult castrated male rats with oestradiol benzoate in combination with the amine-depletors reserpine or tetrabenazine. Oestradiol benzoate alone or followed by treatment with progesterone was less effective. These results indicate that the relationship between activation or components of the female copulatory behaviour and central nervous monoamines exists in the male as well.

In the androgenized female it is possible to substitute the amine depletors reserpine and tetrabenazine for progesterone to activate sexual receptivity. The difference in ability to respond between androgenized animals and the control group was not overcome by treatment with the amine depletors. It seems that reserpine or tetrabenazine treatment is more effective than progesterone in inducing the lordosis response in the oestrogen-primed castrate male. In the oestrogen-primed androgenized female, progesterone and amine depletors gave similar results.

Stomatal Movements: a Yearly Rhythm

WHEN the effects of air pollutants on plants were investigated, the sensitivity of the plants to ozone or irradiated automobile exhaust was found to decrease during the winter months regardless of whether the plants were grown in the greenhouse or in controlled environmental conditions. Because the degree of stomatal opening may influence the degree of injury caused by air pollutants, a year's study of daytime stomatal movements was begun. Light, temperature, atmospheric pressure, relative humidity, time of day and month of year were the parameters studied.

Little has been published about endogenous rhythms with other than 24 h cycles. Bünning found an endogenous annual rhythm in germination of seed of various plant species[1]. Further experiments of his with seed of *Senecio vulgaris* and *Fragaria vesca* have indicated that the embryo assumes the yearly rhythm of the mother plant and that the time of maximum germination capability is independent of the time of seed maturation[2,3]. Bünning and Müssle[4] have since shown a yearly cycle in seed germination which is not affected by storage temperature and cold treatment. Transfer of an endogenous cycle from seed to plant has not been shown.

Certified seeds of *Phaseolus vulgaris* L., variety 'Pinto' (Haney Seed Co., Idaho), from stock stored at room temperature were planted in a standard peat–perlite mix and grown in the greenhouse and in the growth chamber. Two plants were grown in each 10·2 cm plastic pot. The pots were placed in a pan of Hoagland solution. Plants in five pots were started in both the greenhouse and the growth chamber each day.

In the greenhouse, atmospheric pressure, light intensity, temperature and relative humidity varied from hour to hour during the day and from month to month during the year. In the growth chamber, light intensity, temperature and photoperiod were held constant. Air entering the growth chamber and greenhouse was filtered through activated charcoal. Carbon dioxide levels at all seasons were always considerably below the 1,000–1,500 p.p.m. necessary to induce stomatal closure[5]. If there are yearly rhythms in stomatal opening as a result of photoperiod, temperature or changes in light intensity only, no rhythms or a reduced rhythm in the growth chamber would be expected.

The plants in the growth chamber were kept on a 16 h photoperiod under 1,900–2,200 ft.-candles using cool white fluorescent lamps with supplementary incandescent lighting. The temperature was held constant at 27° C during the day and at 21° C during the night. The greenhouse plants were grown under greenhouse temperature and light conditions, which varied throughout the year. The greenhouse experiment lasted from June 1965 until May 1966, and the growth chamber experiment lasted from September 1965 until August 1966.

Stomatal opening was measured with a modified Alvim porometer[6] on the eleventh day after planting. The time required for the manometer to drop from 40 to 30 mm of mercury was taken as the rate of airflow through the leaf and as a measure of the degree of stomatal opening. The readings were taken on the lobe of each primary leaf. Two readings, one on each of the two plants in a pot, were made at 2 h intervals during the day. The first reading was at 8 a.m., and the last reading was at 4 p.m. A new pot was used for each set of two-hourly readings in the greenhouse and in the growth chamber.

Fig. 1 shows that the stomatal openings are the smallest in December on plants grown in both the greenhouse and in the growth chamber. For plants grown in the greenhouse, the small stomatal openings might be attributed to the short photoperiod, the low temperature, or the low light intensity in December. For plants grown in the greenhouse the points on the curve are the monthly average values adjusted for changes in light, temperature and relative humidity. For the plants grown in the growth chamber the values of these factors are constant. The points on the curve are monthly average values of individual measurements. There was no statistically measurable effect of atmospheric pressure on stomatal opening in the greenhouse or the growth chamber.

There is a definite yearly rhythm in stomatal movement in 'Pinto' bean plants grown in the greenhouse and in the growth chamber. In both the greenhouse and the growth chamber the yearly rhythm was statistically significant at the 95 per cent level at least (Fig. 1). All months were significantly different from December, which was taken as the base month. As Fig. 1 shows, stomata of plants grown from November to February do not open as wide as those of plants grown from March to October. The yearly patterns for plants grown in the greenhouse and in the growth chamber are similar. The scale in seconds has been inverted so that the graph can give a clearer picture of the rhythm in stomatal opening. The smaller the stomatal opening, the longer the time required for the manometer reading to drop from 40 to 30 mm of mercury.

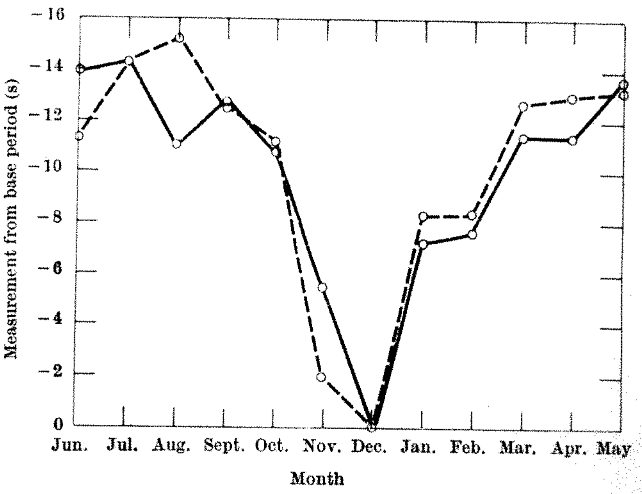

Fig. 1. Seasonal pattern in stomatal opening; —, growth chamber; - - -, greenhouse.

The question arises as to how the plants "know" when the seasons change and adjust their stomatal rhythm. Bünning's findings concerning endogenous rhythms passed on in seeds from the mother plant suggest that a "clock" set within the embryo at the time of seed formation continues to "keep time" as long as the seed remains viable and in this way the rhythm is passed on to the growing plant.

Our data suggest that the clock controlling the yearly rhythm of the stomata was set within the embryo at the time of seed formation. The results suggest also that this clock continues in the young 'Pinto' bean plant at least as long as the primary leaves remain attached.

We thank Hershell Carter for technical assistance, and the staff of Flight Service Station, Federal Aviation Agency, Lunken Airport, Cincinnati, Ohio, for obtaining the atmospheric pressure data.

Red Pine Needle Structure

READERS of the recent article by Kozlowski and Clausen[1] on the anatomical responses of the needles of red pine (*Pinus resinosa* Ait.) to herbicides may have been confused by the extreme variations in needle structure which these authors described and illustrated. Kozlowski and Clausen attributed many of the anatomical differences between "needles" shown in their Fig. 1 to the effects of various herbicides applied to the soil in which the seedlings were grown. From what is known of the leaf structure of pine seedlings[2], however, we concluded that they had illustrated and described three different kinds of foliar appendages of red pine. Their Fig. 1*A*, a transection of a "needle" from a non-treated seedling, seems to be a primary leaf, as is Fig. 1*D* from a treated plant. Their Figs. 1*B*, *C* and *E* are cotyledons, and *F* resembles a shrivelled secondary leaf.

To verify our interpretation of their results, we have re-investigated the anatomy of red pine cotyledons and leaves. We tried to duplicate the experimental conditions of Kozlowski and Clausen, except that no herbicides were used. Red pine seedlings from two sources in Wisconsin were grown in soil in the greenhouse. The first seedlings appeared 3 weeks after planting. The first primary leaves developed 9 weeks after germination. They were followed about 5 weeks later by the first secondary leaves, which are borne in pairs on axillary short shoots. At 13 and 15 weeks after germination, cotyledons and primary leaves were collected from ten representative seedlings. Secondary leaves were collected from nine seedlings at 15 and 26 weeks. All samples were fixed in formalin–acetic acid–alcohol, embedded in tissuemat, sectioned at 12μ, mounted and stained with safranin and fast green.

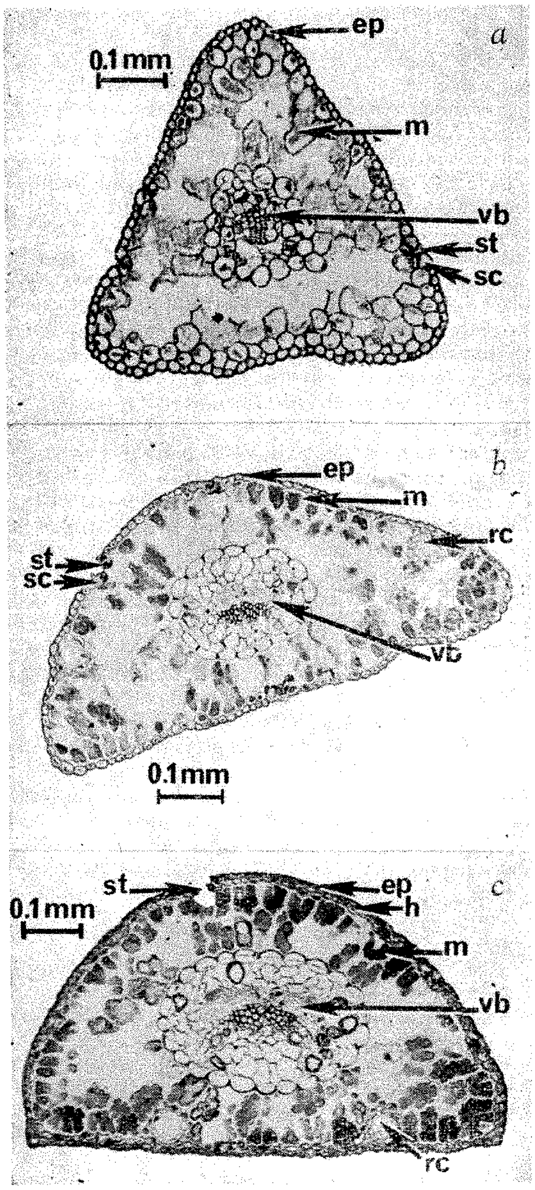

Fig. 1. Leaves of *Pinus resinosa* seedlings in transection: *a*, cotyledon of a 13 week old seedling; *b*, primary leaf of a 15 week old seedling; *c*, secondary leaf of a 26 week old seedling; *ep*, epidermis; *h*, hypodermis; *m*, mesophyll; *rc*, resin canal; *sc*, subsidiary cell; *st*, stoma; *vb*, vascular bundle.

The cotyledons of red pine are readily distinguished from all later-formed leaves by the absence of resin canals and by their triangular shape in transection (Fig. 1*a*). They also differ in having mesophyll cells which are usually rounded or undulate in transection, with most walls lacking internal ridges. The cotyledons have more extensive intercellular spaces than later-formed leaves, and the subsidiary cells of the stomata usually lack a flange. In common with primary leaves, the cotyledons have a single vascular bundle and thin-walled epidermal cells, and they lack a hypodermis.

The primary leaves differ from the secondary leaves of red pine in shape and in position of the resin canals, in addition to the features enumerated earlier: the single vascular bundle; thin-walled epidermis; and no hypodermis (Fig. 1*b*). The shape of the primary leaves in transection is variable, but the adaxial surface tends to be flattened and the abaxial surface rounded. The primary leaves lack the geometrically regular semicircular shape of the secondary leaves, however. The two external resin canals of the primary leaves are adjacent to the abaxial epidermis, in contrast to the adaxial position of the two principal resin canals in the secondary leaves.

Even the first-formed secondary leaves of seedlings have most of the features of the red pine needle illustrated, for example, by Esau[3]: semicircular shape; thick-walled epidermis; well-defined hypodermis; two principal resin canals in contact with the adaxial dermal layers; strongly ridged mesophyll-cell walls; and flanged stomatal subsidiary cells (Fig. 1*c*). Most of the secondary leaves of the seedlings have two vascular bundles—an invariable feature of the secondary leaves of older red pines.

It is clear from earlier work and from our observations that some of the anatomical effects which Kozlowski and Clausen attributed to herbicides are normal differences in structure between different kinds of foliar appendages. They considered these features to be the effects of herbicide treatments: the triangular shape of the treated leaves; the rounded shape of the mesophyll cells; the infrequency of internal ridges on the mesophyll-cell walls; and the extensive air spaces in the mesophyll. But these are all characteristics in which red pine cotyledons (see their Fig. 1*B*, *C* and *E*) usually differ from primary leaves which Kozlowski and Clausen used as a control (see their Fig. 1*A*).

Other effects that Kozlowski and Clausen reported may not have been a result of comparisons of different kinds of foliar appendages; some of these effects resemble herbicide-induced changes in the structure of secondary leavet of red pine reported by others[4]. Their conclusions make is evident, however, that future herbicide investigations which utilize an organism as complex as a pine seedling should be based on an understanding of the variety of foliar appendages that these plants can produce during their first season of growth.

BOOK REVIEWS

WEATHER LONG AGO

Histoire du Climat depuis l'An Mil

(Nouvelle Bibliothèque Scientifique.) By Emmanuel Le Roy Ladurie. Pp. 376+31 plates. (Paris: Flammarion, 1967.) n.p.

IT is now about a hundred and fifty years since the occurrence of ice ages at some time in the more or less distant past was first deduced from the identification of old moraines far down in the valleys of Switzerland and Scandinavia. The discovery was the product of an age that was anxious about current advances of the glaciers. The first arrangements by governments to organize and maintain daily weather observations, in France in 1775 and in Prussia in 1817, were inspired by anxiety over the behaviour of the seasons. There was also at that time an awareness in England and various other parts of Europe that the climate in the early middle ages (and to some extent in the first halves of the sixteenth and eighteenth centuries) had been more genial—enough to affect horticulture and the limits of the vine. It so happened that in the last quarter of the nineteenth century, when the first 100 year-long series of weather observations from a number of places became available for study, the prevailing temperatures after an interval of greater warmth between 1850 and 1875 had reverted to about the same values as when the series began. It was all too quickly concluded by the leading climatologists of the day that the climate was stable and that significant variability belonged only to the geological past. This view found its way into the textbooks; and it was not until about 1950 that the remarkable warming in the present century, which has produced historic retreats of the glaciers in most parts of the world and affected the prospects of agriculture and fisheries almost as widely and had a great impact on human habits, really brought the diagnosis into question. Since then the climatic trend seems to have reversed once more. So there is an urgent need for fuller knowledge and a better understanding of the phenomena of climatic change, to meet the demands of modern long-term economic planning.

Research has been proceeding on a small scale—a surprisingly small scale in relation to the economic stakes involved in forward planning of industrial and agricultural development—here and there wherever there happened to be interested individuals who could make an opportunity and had the necessary skills to pursue it. Institutions with departments fostering research in this field are rare: possibly the only ones deserving mention are the Center for Climatic Research established by Bryson in the University of Wisconsin Department of Meteorology and, for ancient climates, the Quaternary Research Sub-Department set up by Godwin in the Botany School at Cambridge—though other, smaller groups of interested palaeobotanists, meteorologists, oceanographers, geologists, glaciologists, radio-isotope physicists and others, in Scandinavia, central Europe, Russia and the United States have made important contributions to knowledge. The literature of the subject is correspondingly scattered. The quest for facts of past climates, delineation of the wind and ocean circulation patterns which controlled them, and physical interpretation of the development of climatic changes, require an exceptionally broadly based interdisciplinary enterprise which would properly demand the full resources of an interdisciplinary institute. This book is a remarkable testimony to what one brave man, possessed of furious energy and enthusiasm, can do; but it also reveals the breadth of the subject and the need for a co-ordinated attack on it.

Diverse researches on the evidence of the past have already uncovered the outline of a climatic sequence over the 10,000 years since the last ice age, which shows endless fluctuations of differing amplitude and on many time-scales, including a variation within the past thousand years such that the declining warmth and the precipitation changes between about AD 1300 and 1700 must have produced heavy strains on the primitive human economies of the time. Indeed, many of its impacts can be readily demonstrated, though historians have hitherto tended to attribute all such dislocations to the consequences of the Black Death and subsequent recurrences of the dreaded plague.

Historians have sometimes recently come under fire for working without reference to climatic stress except as an enemy the occasional intrusions of which on human affairs have been rare and entirely haphazard. Only in the history of Iceland and Scandinavia have the shifting climatic limits not been ignored—because they could not be. Professor Le Roy Ladurie, of the École Pratique des Hautes Études at Paris, the author of this book on climatic history from the year AD 1000, first found himself driven to the subject in his research on the agricultural history of the Languedoc, in the south of France. Now, after twelve years of wide study and reading, he has had the courage to produce not just a history of Europe which takes account of climatic events but a history of the climate itself.

The effort must have been enormous. The author has acquainted himself with most relevant matters from dendrochronology to radiocarbon and sunspot variation and has attained, on the whole, remarkably balanced judgments. The representative bibliography, like the meticulous documentation of his own historical researches, is a feature of the book. It is scarcely surprising that there are a few faults. One of the most glaring (on page 100), probably an accidental misquote or misunderstanding, concerns my own derivation of estimated average temperatures for the warmest period of the early middle ages. Quoting a summer temperature departure of 2° C above modern values for two centuries at that time, as in the much longer post-glacial warm epoch, Ladurie describes this as exaggerated: the actual published figure[1] derived by my analysis was an anomaly of +0·8° C, which I have mostly described as "about +1° C". Ladurie performs a valuable service to students in stressing the need for critical consideration of ancient texts before using them; but it is wrong to suggest that those meteorologists who have analysed the changing frequencies of various reported phenomena have omitted precautions about this. It is also untrue to say (page 22) that the wide agreement on the climatic sequence derived from these studies—for example, generally falling temperatures from the thirteenth to the seventeenth centuries and with sharper stages around 1315, 1430 and 1560–1600 and some let-ups in between—depends on the use and re-use of the same sources by successive investigators. It has received verification in recent years by the publication of previously unused source material—for example, two items in Ladurie's own bibliography: Titow's study of the weather recorded in the medieval rolls of the bishopric of Winchester[2,3] and Buchinsky's collection of reports contained in the chronicles of the medieval monasteries on the Russian plain[4]. In any case, Ladurie's own picture of the climatic sequence differs only marginally in the magnitude and duration of the intermission which culminated with the warm years of the 1520s and 1530s: on this last detail he produces perhaps the most useful analysis so far (page 236), including a demonstration of the biennial oscillation which is a subject of current interest in general circulation studies.

One regrets a certain undervaluing of the contributions of Flohn and Kraus (in these cases perhaps it is lack of thorough acquaintance), also of earlier pioneers like Huntington, Kinzl and Utterström; though C. E. P. Brooks comes in for legitimate criticism (page 213) for "romancing" about the so-called "little ice age" of recent centuries and putting an "interglacial" into it between 1680 and 1740 on little evidence—actually the 1690s are now known to have been about the coldest decade in Iceland, Norway and Britain, though not in the Alps. Any unfairness has clearly resulted only from the difficulty of attaining, or expressing, a balanced judgment quickly. There is some polemic, probably mainly intended to goad his fellow historians into tackling the subject and producing further critically examined data for scientific analysis. This style of presentation does mean, however, that one has to read a long way before discovering that the author's conclusion (for example, page 31) that the climate has been stable during the past two thousand years or more admits of oscillations great enough to allow several hundred years of disastrous advance of the glaciers (Brooks's "little ice age"—a convenient enough term) and of the polar sea ice.

Ladurie arrives at sensible estimates for the amplitudes and different period-lengths of the various fluctuations. The great glacier advances referred to were produced by a variation of average annual mean temperature amounting to only about 1° C. This should be sufficient warning of the precariousness of practical decisions based on an assumed constancy of climate.

The book makes no attempt at meteorological interpretation and contains not a single weather map. The author seems to have much less appreciation of shifts in world precipitation patterns than he has of temperature, though a selection of Fritts[5] maps of average tree-growth in different decades since 1576 in the western United States are reproduced. Chapters of the book are devoted to: (1) aims of his quest for facts of past climates, (2) the evidence of changes in the forests and vintages, (3) the warming of the climate from 1850 to 1950, (4) the problems and evidence of the "little ice age" which preceded the recent warming, (5) "working hypotheses" (in reality an assessment of the magnitude and course of the temperature changes which underlay the glacier changes of recent centuries), and (6) the turf moor at Fernau in the Austrian Alps. The last-named brings in a useful survey of the longer span of post-glacial climatic history and much little known detail on the sequence of glacier advances and retreats since 1500 BC in that locality; though it is an extreme course to generalize the history of Europe's glaciers from the record of a single one as registered in the peat bog near its snout.

I share the author's earnest hope that this book will serve to awaken interest in the climatic record and encourage many more historians to take it up. In the long run, the chief value of the book will, however, be its remarkable documentation, with the quoting or reproduction of many ancient texts and dated maps and pictures, of the glacier advance and retreat in Europe since AD 1200 as well as the tabulated data year by year since AD 1349 of the French vintages and its analysis of how far the vintage variations were controlled by weather.

It makes a fascinating book and one which will be bought for the charm of its remarkable sequence of pictures of the Rhône glacier and the Chamonix glaciers as well as for reference to the critically examined data it contains.

LABORATORY PHARMACOLOGY

Pharmacological Experiments on Isolated Preparations

By the staff of the Department of Pharmacology, University of Edinburgh. Pp. 131. (Edinburgh and London: E. and S. Livingstone, Ltd., 1968.) 21*s*.

THE publication of this new practical book from Edinburgh will be welcomed by most pharmacologists. Experimental procedures for setting up isolated tissue preparations are described in sufficient detail for a novice to attempt these with every expectation of success. The illustrations are simple and helpful.

There is a wealth of information of particular value to those concerned in the preparation of practical classes, notably about concentrations and doses of drugs, most of which are, quite rightly, expressed on a molar basis. The references have been selected for their relevance to practical details. One appendix tabulates molecular weights and solubilities of drugs. Others deal with the estimation of fiducial limits and the equations of drug-receptor interaction. These are all useful data. An appendix listing the basic apparatus required for the experiments might perhaps be included in a subsequent edition.

The use of capital letters to distinguish pharmacopoeial or approved names from "chemical names when these are simple" is quite unjustified. This convention, not always consistent, coupled with the use of italics for trade names (and for other drugs when these are part of a heading) will confuse rather than help the student.

The description of each experiment begins on a new page; the descriptions of the biological preparations themselves, some of which apply to more than one experiment, are less easily located—a bolder type rather than italics might be helpful. The table of contents is clearly laid out and obviates the necessity for an index.

All the experiments described are exclusively on isolated tissues and so can be performed by students without a Home Office licence. It is surprising how much pharmacology can be taught on tissues *in vitro*. Nevertheless, it is essential for pharmacologists to remember that the experiments in this book should form only a part of any practical course in pharmacology. They must be supplemented by demonstrations on anaesthetized animals and if possible by the students experimenting on decerebrate, spinal or pithed preparations and on themselves. Perhaps the authors could be persuaded to write a further volume dealing with these aspects of practical pharmacology. It would be as well received as I am confident this one will be.

E. W. HORTON

CANCER IN CANADA

Canadian Cancer Conference

Vol. 7: Proceedings of the Seventh Canadian Cancer Research Conference, 1966. J. F. Morgan *et al.* (editors). Pp. 432. (Pergamon Press, 1967.) $18; £6.

THESE volumes serve to bring together the many aspects of cancer research. This latest volume contains twenty-two papers and covers five major areas in the study of cancer. Discussion of cell division and proliferation and of metabolic regulatory systems account for more than half of the contributions. The properties of cell membranes, the effects of radiation on cells, carcinogenesis and cancer epidemiology take up the remainder of the volume. The papers are all of a review nature, but this has not restrained the authors from presenting their personal views and speculations. Each of the papers is so wide-ranging that it is a pity there is no index to help the reader find particular details quickly. The editors are to be congratulated for achieving a uniformly high standard in the presentation and content of the papers in this useful volume.

P. W. BARLOW

ALL WILD LIFE IS HERE

The Penguin Dictionary of British Natural History

By Richard Fitter. Assisted by Maisie Fitter. Pp. 348. (Harmondsworth, Middx.: Penguin Books, Ltd., 1967.) 8*s*. 6*d*.

THE naturalist in the field is the latest person to benefit from the valuable series of Penguin dictionaries.

In this case, as befits a dictionary of natural history, the greatest number of entries are names of animals and plants. There are descriptions of birds, butterflies, fishes, insects, reptiles, flowers, fungi and trees, entered under their common names. The binomial names of each species, and their vernacular equivalents, are given in an index of species at the end of the book. All phyla and classes are also entered and each animal or plant can be fully classified through two names which are given after each species entry. The student and amateur naturalist now have a readily available way of linking common names to scientific names, which they must find useful. The important task of identifying animals and plants is not, of course, aided at all, and the identification manuals are certainly not made redundant.

Although this is not a dictionary which is specifically concerned with biology, terms which are in use with the field naturalist are included. For example, mimicry, polymorphism, gene, polyploid, hetero- and homozygote are explained for the amateur—a mutation is described as "A change in one of the genes of a chromosome". Mitosis, meiosis and other technicalities are not here. Various other ecological and ethological terms are included when they are relevant to natural history. There are also entries dealing with physical, meteorological, geographical and geological phenomena—there is a geological time scale which should be very useful to all those who can never remember the order and dates of the various periods.

A paperback probably will not stand up well to life in the field, and so this dictionary has to be recommended as a useful addition to the naturalist's bookshelf.

MARY LINDLEY

MODERN ALGEBRA

Lectures on Modern Algebra

By P. Dubreil and M. L. Dubreil-Jacotin. Translated by A. Geddes. (University Mathematical Monographs.) Pp. xii + 364. (Edinburgh and London: Oliver and Boyd, Ltd., 1967.) 105*s*. net.

THERE are many textbooks on modern algebra. Most introduce the student to the usual structures, including groups, rings, fields, vector spaces and perhaps lattices. This book does this too; but there is a difference, in that there is a strong motivation coming from a hidden source. What is this source? It is the body of algebraic knowledge now referred to as commutative algebra. Even this subject is of recent origin, arising, as it does, from algebraic deficiencies of a fundamental character thrown up by a study of algebraic geometry. It is rather surprising then that nowhere in the book is there any mention of algebraic geometry or of commutative algebra. The nearest the author comes to this is on page 142 where, in an example, it is remarked that the set of polynomials (of a polynomial ring) "which vanish at a given point, or at k given points, or on a given set of curves and points, is an ideal". It is a pity that the contact with algebraic geometry is so marginal.

In spite of what has been said about motivation there is no doubt that the book is an excellent text for the student of modern algebra. It carefully develops the theory from the most elementary concepts, and, while it contains no exercises, there is a good sprinkling of illustrative examples. A particularly pleasing feature is the inclusion of a chapter on lattice theory (largely in order to discuss the lattice of ideals of a commutative ring) and a chapter on noetherian rings. The last chapter, essentially on field extensions, contains sections on integral dependence and on the famous *Nullstellensatz* of Hilbert. These remarks on content serve to indicate how closely the material in the book is oriented towards commutative algebra. The book is a translation of the second edition of *Leçons d'Algèbre Moderne*, and it is number six in the series of "University Mathematical Monographs". The usual high standard of printing by Oliver and Boyd is everywhere evident.

L. S. GODDARD

BOOK OF SPECTRA

Atlas of Electron Spin Resonance Spectra

By B. J. H. Bielski and J. M. Gebicki. Pp. xiii + 665. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 220*s*.

THE word "Atlas" is a bit misleading. This mammoth book, which must have taken a great deal of time and effort to compile, is more like a rambler's guide book—one of those interesting and often delightful works that take the reader down many quaint by-ways, thereby avoiding terrain that has become commonplace.

This book will appeal to the expert, both as a source of information and as something to browse in. Basically, it consists of well reproduced esr spectra together with the appropriate references, the source of the paramagnetic material, and its nature. The field of organic radicals in fluid solution is quite well covered, as is that of radicals in systems of biological interest. The field of organic or inorganic radicals in solids is very sparse and the huge fields of colour centres and transition metal complexes are almost entirely omitted. For example, there is just one lonely reference to F-centres, and I cannot help feeling that this should have been replaced by a clear statement that F-centres were not covered, together with a list of references to appropriate reviews on the subject.

More serious omissions arise in another way. In recent years many authors to save space, particularly in cases where good spectra have been obtained the interpretation of which is clear, have published the derived parameters rather than the actual spectrum. No mention of these studies is made and hence this atlas cannot in any sense be taken as being comprehensive even in the limited areas covered.

The work is completely uncritical and therefore often very misleading, for many incorrect or improbable "identifications" are quoted. Some of these relate to work of at least ten years ago, the authors of which would surely no longer hold to their original assignments.

A remarkable number of spectra are listed as "unpublished results", and in some cases one realizes why. However, because often no interpretation is then offered, the reader can amuse himself by testing his own interpretative skill.

The order of presentation is often most puzzling, and anyone who decides to read consecutively will be astonished at its vagaries. More serious, however, are the many errors.

The symbol a_{H} is a popular one for these authors and is applied in many cases to describe the hyperfine parameters for a large number of nuclei, not just hydrogen. Certain peroxy-radicals formed in the reaction of hydrogen peroxide with titanous salts are incorrectly described as the hydroxyl radical. The *N*-methyl pyridinium ion is said to be the source of an interesting esr spectrum and is described as the methylviologen cation radical.

The reader may be taken aback by the large number of spectra assigned to nitrogen dioxide. In fact, only two of these are anything to do with NO_2, the others being, in my opinion, various radicals formed by reaction between NO_2 and either the solvent or impurities contained therein.

Radicals described as NH_3^-, $C_2H_2^+$ and allyl alcohol diradicals are without doubt other species than these, and the presence of a hyperfine splitting from ^{129}Xe in irradiated CF_4 is certainly surprising !

It would scarcely seem necessary to illustrate spectra for polycrystalline diphenylpicrylhydrazyl, or indeed for aqueous Mn^{2+}, but to find both these spectra referenced as "unpublished results" is quite astonishing.

M. C. R. SYMONS

SENSE OF PERSPECTIVE

The Graphic Work of M. C. Escher

Pp. 24+69 plates. (London: Oldbourne Book Co., Ltd., 1967.) 42*s*. net.

"ALTHOUGH I am absolutely innocent of training or knowledge in the exact sciences," Escher writes in the introduction to this book, "I often seem to have more in common with mathematicians than with my fellow artists." In the principles of symmetry, inversion and topology that so dominate his work, Escher shares a common interest, superficially at least, with chemists and crystallographers as well as with mathematicians. Yet scientists no less than others will wonder whether the intriguing visual paradoxes that Escher conjures forth from the formal qualities of line and plane in fact transcend their own virtuosity.

Escher's impossible buildings, achieved by subtle perversions of the rules of perspective, are among the best known of his works. A genre that he has made his own is the exact filling of a space with two or more sets of discrete objects which interlock perfectly with each other. Another common theme is the blending into one composition of two mutually incompatible situations. "Day and Night", for example, shows on the left hand black birds flying over a daytime landscape and on the right hand white birds flying over the mirror-image landscape under cover of darkness; the centre of the picture, with remarkable dexterity, merges the two flocks of birds into each other and into the contraposed landscapes.

But after the tricks and the *trompe-l'oeil*, what remains ? Is there a serious substance in these drawings, or are they to be dismissed as amusing exercises in technique, no more significant than the visual illusions beloved of psychologists ? Escher himself points out that two of his motifs were taken from an article in the *British Journal of Psychology*, and the bizarre naivety of the grinning fishes and dwarflike men that populate many of the drawings cannot but confirm the impression of frivolity.

Beneath the pyrotechnics there is, perhaps, a profounder purpose. Lévi-Strauss, possibly with tongue untypically in cheek, has remarked of abstract art that it is concerned with style, not content, and that an abstract work shows the manner in which the artist would execute his pictures if he were by chance to paint any. In a similar way it seems that Escher is preoccupied with the conventions of representing three dimensions in two, and that his pictures are inquiries into the logic of perspective and the assumptions made both by the hand of the artist and the eye of the beholder. Escher says in his notes on the pictures, "The two dimensional is every bit as fictitious as the four dimensional, for nothing is flat". His work is an exploration of the absurdities that spring from this fiction and, it may seem, is a statement of the problems to be overcome before he could himself portray the world as he sees it. The plates grouped under the heading "Conflict between the Flat and the Spatial" are a remarkable and not merely entertaining exposition of these absurdities.

At two guineas this book is moderately priced, and to those who decline to accept it as art, its illusions should give a good run for their money. N. M. L. WADE

OBITUARIES

Professor J. L. B. Smith

PROFESSOR J. L. B. SMITH, the South African ichthyologist, died at his home in Grahamstown on January 7, 1968. At the time of his death he held the research professorship of ichthyology at Rhodes University.

Professor Smith's name will always be associated with the discovery and description of the extant coelacanth crossopterygian, *Latimeria chalumnae*, captured in December 1938 near East London. The circumstances surrounding this event, and the subsequent fourteen-year-long campaign to obtain a second specimen, were vividly described by Smith in his book *Old Fourlegs* (1956). This account revealed (as its author realized) a great deal of the man, and rarely can have been equalled as a frank character-study of a determined and dedicated man.

Born at Graaff Reinet in 1897, Professor Smith was educated at a number of schools including "Bishops" College, and the Victoria College, Stellenbosch. It was at Stellenbosch that his interest in chemistry was first aroused, and it was as a chemist that he joined Rhodes University College, Grahamstown, as a lecturer in 1923, after obtaining a Ph.D at Cambridge. During the First World War, Smith served with the South African Forces in East Africa.

From 1923 until 1947 Smith lectured in chemistry at Rhodes, producing several papers and three textbooks on chemical subjects. His spare time, however, was largely devoted to studying fishes. It was during this period that, in addition to his work on the anatomy of *Latimeria*, he laid the foundations for his most widely known work, *The Sea Fishes of Southern Africa*. In 1947, the South African Council for Scientific and Industrial Research awarded Smith a research fellowship which enabled him to resign his post in the chemistry department and thereby devote his full energies to ichthyology.

Smith's interest in fishes stemmed from an early contact with them as a sea-angler. This introduction left its mark on all his subsequent work which, as far as possible, he based on personal acquaintance with the fishes in the field. His love and enthusiasm for angling, and his appreciation of the angler's problems, led Smith into wide and profitable contact with the public. There is probably no other ichthyologist who can claim to have had queues forming outside bookshops on the day his regional monograph was published. Yet this was the reception that Smith's great work *The Sea Fishes of Southern Africa* received in 1949.

Essentially synoptic in its treatment, *Sea Fishes* was followed by a series of family and generic revisions of species from South African waters and the western Indian Ocean, as well as numerous shorter papers dealing with new taxa. In 1963, Smith and his wife published another important regional synopsis, *Fishes of the Seychelles*, covering an area the marine fauna of which had received scant attention since the mid-nineteenth century. In all, Smith produced more than two hundred papers and articles on ichthyological subjects.

Although there is a long history of ichthyological research in South Africa, Smith's investigations have undoubtedly added more to our knowledge of the fishes from this vast marine area than have those of any of his predecessors. Smith's work was essentially pioneering, and his attitude that of a field-worker faced with the task of mapping a complex and rich fauna still imperfectly known. At times this brought him into conflict with European and American workers, particularly on questions of nomenclature. The momentary heat-haze generated by these differences cannot, however, obscure the fact that J. L. B. Smith's drive and dedication resulted in a very significant contribution to ichthyology.

Professor Smith is survived by his wife, Margaret M. Smith, who was his close collaborator in the field and laboratory, and who was responsible for most of the illustrations in his many papers. P. H. Greenwood

Professor George Macdonald

Professor George Macdonald, one of the most dominant figures in the world of tropical medicine for twenty years, died on December 10, 1967, in University College Hospital.

The son of John Smyth Macdonald, FRS, Professor of Physiology at Sheffield and later at Liverpool, George Macdonald graduated M.B., Ch.B. at Liverpool University in 1924 at the age of 21 and took his D.T.M. in the same year. In 1925 he went as a research assistant to the Sir Alfred Jones Laboratory at Freetown, Sierra Leone, and in 1926 he published the first of his many papers on malaria. After graduating M.D. Liverpool and taking the London D.P.H. in 1932, he spent seven years in India and Ceylon and returned to England as assistant director of the Ross Institute in 1939. He joined the Royal Army Medical Corps and after a short period as D.A.D.H. Salisbury Plain Area he was appointed to form and command the first Malaria Field Laboratory. This unit had an adventurous career in Greece and Crete.

In 1942 he was appointed consultant malariologist to the Middle East Forces, and his advice saved the Eighth Army from burdening itself with hundreds of tons of antimalarial equipment during its advance to Tripoli. In 1947 he became the first professor of tropical hygiene at the London School of Hygiene and Tropical Medicine, and director of the Ross Institute.

He was a pioneer throughout his life. In Ceylon he devised an automatically flushing siphon for antimalarial drainage, the appearance of which was followed by a spate of "new and improved models". In London, when he turned his mind to the quantitative epidemiology of malaria, the answers to entomological questions he posed were not available; his reaction was to set up the Ross Institute's own entomological unit, now an established leader in research on anophelines. In 1957 he published his collected malariological work in *The Epidemiology and Control of Malaria* (O.U.P.), a book which mathematicians and others could read with equal pleasure and profit. He was a member of the World Health Organization's Expert Committee on Malaria from its inception, and (theoretical though his work seemed to some people) on several occasions he reasoned out epidemiological methods with strictly practical field application.

The epidemiology of malaria, an asexual infection in man, involved relatively simple mathematical calculations which were soluble with hand calculators—and with help from professional statisticians which he freely acknowledged. When he turned his mind to helminthic and therefore sexual infections the aid of a computer was needed. Characteristically, he learned to produce his own programmes and in due course published a mathematical model for the epidemiology of schistosomiasis. This too has thoroughly practical implications, not least in initiating healthy controversy in a new subject.

As a teacher Macdonald tended to lecture above cloud level. But his formidable brainpower and concentration were freely available to anyone who went to his office, and he solved the problems of hundreds of callers, correspondents and committees. He met the knowledge of impending death with great mental and physical courage, carrying on creative work and inspiring others to the last possible moment.

He was made C.M.G. in 1953, and received the Darling Foundation Award in 1954 and the Bernhard Nocht Medal in 1963. He was president of the Royal Society of Tropical Medicine and Hygiene in 1965–67.

B. B. Waddy

Professor Frank Raw

Professor Frank Raw died suddenly, in his forty-seventh year, on October 1, 1967, in Brisbane. He had been professor of entomology in the University of Queensland, Australia, for six months.

Graduating from Queen Mary College, University of London, in 1942, Raw began research in Cambridge under Salt and Hollick with the war-time team studying wireworms in agriculture, work which included pioneer studies of the general arthropod fauna of pasture and arable soils—a subject that remained Raw's chief interest. After two years he became an advisory entomologist at the Research Station, Long Ashton, later transferring to the National Agricultural Advisory Service, where he continued his work on insects of pasture soils with a broad ecological study of the garden chafer beetle.

In 1948 Raw joined the staff of Rothamsted Experimental Station, and remained there until 1967, specializing in the agricultural aspects of soil zoology. During this period, however, he spent two years at the West African Cocoa Research Station, in what was then the Gold Coast, studying the control of cacao capsids with chlorinated hydrocarbon insecticides; this early work has since led to much improvement in cacao growing.

Raw's work very successfully combined fundamental and practical approaches, and his zoological studies were always related to the effects of soil animals on the yield of crops, an aspect of research in agricultural entomology still much neglected. He continued to study the biology of wireworms at Rothamsted and he made experiments in collaboration with the insecticides department on the chemical control of these pests especially with chlorinated hydrocarbon seed-dressings; this notably contributed to current methods of control. Nevertheless, he also studied side-effects both of chlorinated hydrocarbon and of organophosphorus insecticides on the invertebrate animals in the soil. By improving methods of extracting these animals he revealed the unexpected abundance of Protura, a group that had before been considered as being sparse.

Raw's work on earthworms is well known and his technique of using formalin for sampling populations of worms is now a standard method. He showed, especially in apple orchards, how weather and chemical sprays affected the abundance and activity of worms, how these changes affected the burial of fallen leaves and the incorporation of leaves into the soil as nutrients for the trees; this work also raised problems of the removal from orchards of the spores of the fungus causing apple scab when worms buried dead leaves.

In his studies of the wheat-bulb fly, cut short at a most promising stage, he related the population dynamics of the insect to damage done to wheat crops. He studied the effects of fallow, both locally and nationally, of seed-rates, tilth, fertilizer treatment and different varieties of wheat on the response of the crop to attack by this pest. Raw was more aware than most workers that the abundance of a pest is only one of the many factors to be considered when studying loss of yield on crops caused by insect attack and that various ecological interactions between crop, pests and associated organisms are important in agricultural entomology. He had a special ability, not common among research entomologists, to see pests in a broad agricultural context. This wide approach is evident in Raw's publications and especially in his joint editing of the recent treatise, *Soil Biology*.

Raw was, for long, an active officer of the Association of Applied Biologists and for the past seven years its esteemed treasurer.

It was expected that he would influence the subject of agricultural entomology greatly in his new appointment, for his clarity of thought and of exposition was exceptional. C. G. Johnson

University News:

Glasgow

DR JOHN H. SUBAK-SHARPE, at present a member of the staff of the MRC Experimental Virus Research Unit in the Institute of Virology at Glasgow, has been appointed to the chair of virology in succession to Professor M. G. P. Stoker, who has been appointed to the directorship of the Imperial Cancer Research Fund Laboratories in London. Dr Subak-Sharpe will also succeed Professor Stoker as honorary director of the Experimental Virus Research Unit.

London

MR R. G. BURWELL, senior registrar at the Robert Jones and Agnes Hunt Orthopaedic Hospital, has been appointed to the chair of orthopaedics tenable at the Institute of Orthopaedics.

Newcastle upon Tyne

DR D. H. WHIFFEN, at present superintendent of the Division of Molecular Science in the National Physical Laboratory, has been appointed to the chair of physical chemistry.

Appointments

THE Royal Society has made its ninth appointment to a Royal Society research professorship and the holder of this appointment is Professor H. C. Longuet-Higgins, honorary professor in the Department of Machine Intelligence and Perception, University of Edinburgh, and until 1967 John Humphrey Plummer professor of theoretical chemistry in the University of Cambridge. Professor Longuet-Higgins will take up his appointment on April 1 and will work at the University of Edinburgh.

Announcements

THE Scientific Medal of the Zoological Society of London has been awarded to the following in recognition of their distinguished work in zoology: Dr J. B. Gurdon, Department of Zoology, University Museum, Oxford, for his work on nuclear transplantation; Dr J. E. Treherne, Department of Zoology, University of Cambridge, for his work on insect physiology, particularly the absorption of nutrients; Professor L. Wolpert, Middlesex Hospital Medical School, London, for his work on cell biology and embryology.

THE Institution of Mechanical Engineers has awarded the James Clayton Prize jointly to Professor F. T. Barwell of the Mechanical Engineering Department, University College, Swansea, and Mr Frank Nixon, chief consultant at Rolls-Royce Ltd., Derby.

THE following addendum has been sent by Dr Kenneth S. Warren and refers to the article "Cercariae of *Schistosoma mansoni* and Plants: attempt to penetrate *Phaseolus vulgaris* and *Hedychium coronarium* produces a Cercaricide", which appears on page 647 of this issue: Recently it was noted that cercariae are attracted to only certain varieties of green string beans. Although there were no obvious differences among the beans tested, this phenomenon is under investigation.

ERRATUM. In the communication "Solar Oblateness and the Perihelion Advances of Planets" by J. J. Gilvarry and P. A. Sturrock (*Nature*, **216**, 1283; 1967) the third paragraph on page 1284 should begin: "Because the accuracies in the determinations of the perihelion advances of Venus and the Earth are inadequate for the purpose, the only natural planet that could be conjoined with Mercury for a test equation (1) is the asteroid (1566) Icarus[9]. For this minor planet, the advance of the perihelion predicted by general relativity is 10·1 sec/century, exceeding that of any planet except Mercury[9], and the advance arising from solar oblateness would be 15·7 sec/century . . .". The sixth line of the second paragraph on page 1285 should read "with no observational disagreement", and not "with an observational disagreement". In the sixteenth line of the fourth paragraph on page 1285 reference 11, not reference 8, should be mentioned, and reference 16 should be inserted at the end of the following paragraph. This article was received on September 12, 1967, and not revised as indicated. The following note was added in proof: It has been pointed out recently by J. Ashbrook (*Sky and Telescope*, **34**, 229; 1967) that the results of Dicke and Goldenberg differ sharply with the careful observations of W. Schur and L. Ambronn by means of a heliometer over the period 1891–1902 (essentially a sunspot cycle) implying only an insignificant solar oblateness. Their values are less than one-hundredth, at most, of that reported by Dicke and Goldenberg. In reply, the latter value is defended by Dicke (*Sky and Telescope*, **34**, 371; 1967) as based on a differential measurement between the limbs, rather than on a visual measurement from limb to limb.

ERRATUM. In the communication "Imidazole and Sequestration of Calcium Ions by Sarcoplasmic Reticulum" by B. P. Yu, E. J. Masoro and F. D. DeMartinis (*Nature*, **216**, 822; 1967) the figures were wrongly numbered. The legend of Fig. 4 should accompany the graph of Fig. 5, the legend of Fig. 3 should accompany the graph of Fig. 4, and the legend of Fig. 5 should accompany the graph of Fig. 3. (A previous erratum to this communication should be ignored.)

ERRATUM. In the communication "Transducing Phage for *Pseudomonas putida*" by B. W. Holloway and P. van de Putte (*Nature*, **217**, 459; 1968) the phage *PMBL-4B*1 was incorrectly described as *PMBL-4Bl*.

CORRIGENDUM. In the communication "Mechanism of Olfactory Transduction" by Barnett Rosenberg, T. N. Misra and Robert Switzer (*Nature*, **217**, 423; 1968) the sentence beginning on line 23 of the right hand column of page 426 should read: "In the dark, the conductivity of crystalline chlorophylls was again higher, and the adsorbed gas could be easily desorbed. This process of irradiation and desorption could be repeated a few times, with diminishing effects, until it almost disappeared".

CORRIGENDUM. In the communication "Instability of Amitriptyline Base" by C. R. Henwood (*Nature*, **216**, 1039; 1967) Fig. 1*b* was incorrectly drawn. The carbonyl group should be attached to the ortho positions of the benzene rings as in Fig. 1*a*.

CORRESPONDENCE

Mink in the Wild

SIR,—In the issue of *Nature* of January 6 (**217**, 9; 1968), you published an interesting note on "Mink in the Wild".

Apart from a disagreement with the Ministry of Agriculture about the significance of the damage which "escaped" mink do, I want to point out a misunderstanding concerning the reproduction. On p. 10 it is mentioned that "The young are born in March . . .". This is completely wrong. The mink has its breeding season in March. The length of gestation period is on average 49 days, that is the young are born at the beginning of May, ranging from late April to middle of May.

Yours sincerely,

O. VENGE
prof. dr. agro.

The Royal Veterinary and
Agricultural College,
Department of Animal Genetics
and Animal Breeding,
Copenhagen V, Denmark.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk are open to the public*)

Monday, February 19—Wednesday, February 21

Materials Science Club (at the City University, St. John Street, London, EC1)—Informal Meeting on "Materials for Fuel Cells and High Energy Density Rechargeable Batteries".

Tuesday, February 20

Society of Chemical Industry, Agriculture Group (at 14 Belgrave Square, London, SW1), at 10.30 a.m.—Meeting on "Practical Problems in the Analytical Control of the Animal Food Trade".

Institution of Electrical Engineers (joint meeting with the Automatic Control Group of the I.Mech.E., The Iron and Steel Institute, and the Institute of Measurement and Control, at Savoy Place, London, WC2), at 11 a.m.—Colloquium on "The Design of Mechanical and Electronic Equipment for Automatic Control in the Steel and other Heavy Industries".

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5.30 p.m.—Mr P. G. McLaren: "Static Sampling Distance Relays".

University of London (at the Institute of Child Health, Guilford Street, London, WC1), at 5.30 p.m.—Dr Naomi Datta: "The Vectors of Antibiotic Resistance in Bacteria". (Twelfth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)*

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "Electrical Auxiliary Systems for Nuclear Power Stations".

Society for Analytical Chemistry, Microchemical Methods Group (at "The Feathers", Tudor Street, London, EC4), at 6.30 p.m.—Discussion Meeting on "Automatic C.H.N. Analyzers".

Society for Analytical Chemistry, Special Techniques Group (in Lecture Theatre "C", Chemistry Department, Imperial College, London, SW7), at 6.30 p.m.—Professor W. Klyne: "Optical Rotatory Dispersion and Circular Dichroism; Applications in Structural and Stereochemical Studies"; Dr R. D. Gillard: "Circular Dichroism and its Analytical Potential".

Wednesday, February 21

Royal Institution, History of Science Discussion Group (at 21 Albemarle Street, London, W1), at 1 p.m.—Professor D. M. Newitt: "Origins and Growth of Chemical Engineering".*

Royal Society of Arts (at John Adam Street, Adelphi, London, WC2), at 2.30 p.m.—Dr H. A. Cole: "The Scientific Cultivation of Sea Fish and Shell Fish".

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5.30 p.m.—Mr H. G. Riddlestone: "Standardization and Approval of Electrical Equipment for Use in Hazardous Atmospheres".

Mental Health Research Fund (in the Edward Lewis Theatre, Middlesex Hospital Medical School, Cleveland Street, London, W1), at 5.30 p.m.—Dr Lyman C. Wynne (National Institute of Mental Health, Bethesda): "Schizophrenics and Their Families—Recent Research Findings and Implications" (Sixth Mental Health Research Fund Lecture).

Society of Instrument Technology (at the A.E.I. Cinema, 33 Grosvenor Place, London, SW1), at 5.30 p.m.—Mr B. W. Balls: "The Place of Computers in Process Control".

University of London (at the Institute of Child Health, Guilford Street, London, WC1), at 5.30 p.m.—Professor A. P. Waterson: "Viruses and Virus Diseases". (Second of three lectures on "The Scientific Basis of Dentistry" organized by the British Postgraduate Medical Federation.)*

Institution of Electronic and Radio Engineers, Aerospace, Maritime and Military Systems Group (at 9 Bedford Square, London, WC1), at 6 p.m.—Symposium on "Integrated Harbour Surveillance Systems".

University of London (at the Institute of Archaeology, 31–34 Gordon Square, London, WC1), at 6 p.m.—Mr G. P. B. Naish: "Sources of Maritime Archaeology—Early Ships in Britain".*

Wednesday, February 21—Friday, February 23

Institution of Mechanical Engineers (jointly with the National Council for Quality and Reliability, Ministry of Defence, at 1 Birdcage Walk, Westminster, London, SW1)—Conference on "The Reliability of Service Equipment".

Thursday, February 22

University of London (in the Anatomy Theatre, University College London, Gower Street, London, WC1), at 1.20 p.m.—Mr N. J. B. Plomley: "The Tasmanians—The Extinction of a Race".*

Society of Chemical Industry, Microbiology Group (joint meeting with the Food and Nutrition Subjects Group of the Royal Society of Health, at the Royal Society of Medicine, 1 Wimpole Street, London, W1), at 2.15 p.m.—Meeting on "Water Pollution and Food Production".

Royal Society (at 6 Carlton House Terrace, London, SW1), at 4.30 p.m.—Professor A. Neuberger, CBE, FRS, Mr A. Gorchein and Mr G. H. Tait: "The Formation of Chromatophores in *Rhodopseudomonas spheroides*; an Example of Cellular Differentiation".

University of London (in the Physiology Theatre, University College London, Gower Street, London, WC1), at 5 p.m.—Professor J. Baddiley: "Bacterial Cell Walls" (further lecture on February 29).*

Institute of Petroleum, Exploration and Production Group (at 61 New Cavendish Street, London, W1), at 5.30 p.m.—Mr W. H. Berry: "Construction of the Shell–Esso 30″/4″ Twin Submarine Pipeline from North Sea Block 49/26 to the Norfolk Coast".

University of London (at the Institute of Child Health, Guilford Street, London, WC1), at 5.30 p.m.—Dr R. C. Valentine: "Virus Structure". (Thirteenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)*

University of London (at the School of Pharmacy, Brunswick Square, London, WC1), at 5.30 p.m.—Dr G. J. Popjak: "Biosynthesis of Sterols and Polyisoprenoids. I. Biochemical Aspects" (further lecture on February 23).*

Institution of Mechanical Engineers, Hydraulic Plant and Machinery Group (Fluid Machinery Section) (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "Hydraulic Stability of Pump Operations".

Society of Chemical Industry, Plastics and Polymer Group, Carbon and Graphite Group, and the London Section (joint meeting with the London Section of the Plastics Institute, at the Institution of Electrical Engineers, Savoy Place, London, WC2), at 6 p.m.—Dr L. N. Phillips: "Carbon Fibre Reinforced Plastics".

Friday, February 23

Royal Institution, Photochemistry Discussion Group (joint meeting with the University of Sussex, at the Royal Institution, 21 Albemarle Street, London, W1), at 10.30 a.m.—Meeting on "Spectroscopy and Photochemistry".

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5.30 p.m.—Discussion Meeting on "Operational and Economic Implications of Generating Plant Mix on Future Power Stations".

Royal Institution (at 21 Albemarle Street, London, W1), at 9 p.m.—Professor J. W. Boag: "Pulse Radiolysis".

Saturday, February 24

Inner London Education Authority (at the Horniman Museum, London Road, Forest Hill, London, SE23), at 3.30 p.m.—Mr William C. Sturtevant (Smithsonian Institution, Washington): "Indians of Eastern North America—Their History and Present State".*

Monday, February 26

University of London (in the Anatomy Theatre, University College London, Gower Street, London, WC1), at 5.30 p.m.—Professor A. W. Merrison: "The Science and Engineering of Elementary Particle Physics" (further lectures on March 4 and 11).*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Junior Research Associate or Research Associate (honours graduate in physics and/or geology) in the School of Physics for geophysical studies of the East African Rift System under the direction of Dr R. W. Girdler—The Registrar, The University, Newcastle upon Tyne 2 (February 26).

Lecturer and a Demonstrator (preferably applicants working in the fields of cellular and chemical biology, embryology and animal behaviour) in the Department of Zoology—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh, Scotland (February 28).

Lecturer (physicist or electrical engineer with a Ph.D. degree or similar research experience) in the School of Electrical Engineering, University of New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, February 29).

Senior Lecturer/Lecturer (with a good honours degree in psychology and research interests in the areas of social psychology and/or language development) in Education—The Secretary, The University, Stirling, Scotland (February 29).

Head (with high academic qualifications, several years' research experience, and preferably some knowledge of computing and programming languages) of the Statistics Section—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (March 2).

Lecturer (with previous research experience in aeronomy, preferably ionospheric physics) in Upper Atmospheric Physics in the Department of Environmental Sciences—The Secretary, University of Lancaster, University House, Bailrigg, Lancaster, quoting Ref. L 283/A (March 2).

Assistant Lecturer or Lecturer in Statistics or Operational Research in the Department of Theoretical Mechanics—The Registrar, The University, Nottingham (March 4).

Fellow in South-East Asian Studies, with specific reference to the regional geography of South-East Asia, in the Department of Geography—The Registrar, The University, Hull (March 4).

Lecturers (2) in Pathology at the Royal Infirmary, Glasgow—The Secretary of the University Court, The University, Glasgow (March 8).

Assistant Lecturer in Sociological Studies—The Registrar, The University, Sheffield (March 9).

Assistant Lecturer (with special qualifications in cellular, neuro-muscular or general physiology) in the Department of Zoology—The Registrar, University College, Cathays Park, Cardiff (March 9).

Senior Lecturer in the Department of Probability and Statistics—The Registrar, The University, Sheffield (March 11).

Chair of Morbid Anatomy at King's College Hospital Medical School—The Academic Registrar (A), University of London, Senate House, London, WC1 (March 15).

Chair of Numerical Analysis at Chelsea College of Science and Technology—The Academic Registrar (A), University of London, Senate House, London, WC1 (March 18).

Biochemist to assist with investigations in children in a busy routine laboratory; and a Chemist (with experience in gas chromatography) to join a team working on metabolic disorders in children—The Chemical Pathologist, Hospital for Sick Children, Great Ormond Street, London, WC1.

Lecturer (preferably with experimental interests) in Aeronautical Structures to assist in undergraduate and postgraduate teaching and research—The Professor of Aeronautical Structures, Department of Aeronautics, Imperial College of Science and Technology, London, SW7.

Research Demonstrator (with a good degree in botany or horticulture) in the Department of Horticulture, to assist with laboratory classes and carry out research in plant physiology—Professor O. V. S. Heath, FRS, University of Reading Horticultural Research Laboratory, Shinfield Grange, Reading, Berkshire.

Sedimentary Petrologist, an Exploration Geochemist, and an Exploration Geophysicist (all appointments involve instruction at the graduate and undergraduate level, and participation in research programmes)—The Chairman, Department of Geology, The University of New Brunswick, Fredericton, NB, Canada.

Solid State Physicists (Experimental and Theoretical) for teaching and research—Dr A. H. Morrish, Head, Department of Physics, University of Manitoba, Winnipeg 19, Manitoba, Canada.

Temporary Lecturer (with a good honours degree in psychology, some experience in teaching and research, and capable of taking charge of introductory courses in experimental psychology) in **Psychology**—The Registrar, University of Strathclyde, George Street, Glasgow, quoting Ref. 1/68.

Temporary Lecturers (2) (pure or applied mathematicians) in the **Department of Mathematics**—The Secretary, University College London, Gower Street, London, WC1.

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one or two copies of NATURE each week is:

***12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire.................................**£14.0.0** each
United States of America..........(by air freight)........**$48** each
Canada............................ (by air freight) .... **$52** each
Elsewhere overseas by surface mail .... **£14.0.0** each

(Charge for delivery by air mail on application)
*Shorter periods *pro rata*. (Minimum three months.)

MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

12 MONTHS (52 issues and 4 indexes)

Number of Copies	*G.B. & Eire*	*U.S.A.*	*Canada*	*Elsewhere (surface mail)*
		(by air freight)		
	Each	*Each*	*Each*	*Each*
3–5	**£13.10.0**	**$46.50**	**$50.50**	**£13.10.0**
6–11	**£12.15.0**	**$44.50**	**$48.30**	**£12.15.0**
12 or more	**£12.0.0**	**$42.50**	**$46.00**	**£12.0.0**

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual or department at the same address. (ZIP essential for U.S.A.)

Kent instruments for Process Chromatography

Kent process chromatography instrumentation meets every requirement in trend recording, ratio control of two chromatography peaks and direct process control. The equipment is versatile and is compatible with any proprietary analyzer. Kent Mark 3 (10 in. chart) and Record Graphic (4 in. chart) recorders provide a choice of single and multipoint recording. The range also includes ratio process controllers, two-stage peak store and servo-followers with alarms.

Kent specialist engineers are ready to advise on peripheral equipment for any process chromatography system, with electric or pneumatic control, in any industry, anywhere in the world.

Test our service – telephone Mr. G. H. Sharp Luton 21151 or write for details by return.

APPOINTMENTS VACANT

MEDICAL RESEARCH COUNCIL

CLINICAL AND POPULATION CYTOGENETICS RESEARCH UNIT
DEVELOPMENTAL BIOLOGIST or BIOCHEMIST

There is a vacancy for a biologist or biochemist to join a small team working on pattern formation in cell cultures with particular reference to the behaviour of connective tissue cells and the morphogenetic role of the extra-cellular matrix. It is intended to direct this work towards the study of developmental disorders and tumours in man. The appointment is suitable either for a British scientist, on a three year appointment in the first place, or for an overseas scientist who could join as a visiting worker. Applicants should have a Ph.D. or equivalent in biology or biochemistry and preferably some post-doctoral experience of developmental studies. Remuneration in accord with age and experience on the Council's scales for their scientific staff.

Applications together with details of experience and the names of two referees should be sent to the Administrative Officer, Clinical and Population Cytogenetics Research Unit, Western General Hospital, Crewe Road, Edinburgh, 4.
(540)

UNIVERSITY STAFF

CALGARY, ALBERTA

The Geology Department expects to make appointments of one of the following specialists :

GEOPHYSICIST : Person expected to develop research and courses with emphasis on exploration for metallic mineral deposits.

ENGINEERING GEOLOGIST : Person expected to develop research and courses in engineering geology. Experience in ground water hydrology and surficial geology an asset.

Level of appointment for above positions would be commensurate with ability and experience. Applicants with Ph.D. degrees will receive preference. Presently the Department has 11 staff members and modern facilities. Calgary is 40 miles east of the Rocky Mountains, has a population of 360,000 and is the centre of the oil industry in Canada.

Submit applications, with résumé and names of three referees, to Dr. P. S. Simony, Geology Department, The University of Calgary, Calgary, Alberta, Canada. (603)

UNIVERSITY OF ALBERTA

FACULTY OF AGRICULTURE
VACANCY

Assistant Professor of Animal Physiology, Department of Animal Science. Ph.D. with emphasis on environmental physiology and energy metabolism. Teaching and research ; unique facilities for cold environment studies. Starting salary approximately $10,500 ; appointment effective preferably by July 1, 1968.

Forward applications, including curriculum vitae, transcripts and names of three referees, before April 15 to Head, Department of Animal Science, University of Alberta, Edmonton, Alberta. (471)

GRADUATE ASSISTANTSHIPS IN BIOCHEMISTRY AND MOLECULAR BIOLOGY

Teaching and research assistantships leading to M.Sc. and Ph.D. degrees available for academic year 1968-69. Modern laboratories with excellent facilities. Wide variety of research projects. Stipend for teaching assistantships, $3,700 plus travel allowance and remission of fees. Stipend for research assistantships from $3,000 for 12 months.

Apply Head, Department of Biochemistry, University of Alberta, Edmonton, Alberta, Canada.
(573)

ICI

PHARMACEUTICALS DIVISION

ALDERLEY PARK
RESEARCH LABORATORIES

Physiologists/ Pharmacologists

Applications are invited for the following posts from graduate physiologists or pharmacologists with post-graduate research experience at least to Ph.D level

1. For work with a team engaged in exploring in depth the action of drugs on the heart and circulation generally. Recent developments are most interesting and the work should have great appeal to a good research person.
2. For work designed to lead to the discovery of better drugs for the treatment of mental illness and of drugs to improve mental functioning. Work of considerable interest is already in progress.
3. For reproductive studies designed to lead to better control of fertility in animals and man.
4. For studies on gastric secretion to extend and develop work of promise and considerable interest already proceeding.

The facilities and the environment provided at Alderley Park are recognised as excellent by all who know them. The research staff covers a wide cross-section of the Life Sciences; many of them have international reputations in their fields. Team work is encouraged.

The attractive conditions of service would be discussed at interview. The successful candidate, if married, may receive a reasonable refund of removal and travel expenses and, if necessary, assistance in house purchase.

Applications, giving brief details of age, qualifications and experience should be addressed to :—

1966 1967

J. Leak, Senior Personnel Officer,
Imperial Chemical Industries Ltd.,
Pharmaceuticals Division,
Alderley Park, Macclesfield,
Cheshire.

NATURE Volume 217 FEBRUARY 24, 1968

What Price Roads?

ROMANTIC attitudes towards highways must now be almost extinguished in industrial societies, what with traffic accidents, air pollution and the like. Any doubts that may remain will, however, be dispelled by the appearance in the past week of a series of economic calculations by the Ministry of Transport which is intended as a basis for future attempts to apportion the costs of operating the highways system between the different classes of road users (*Road-Track Costs*, HMSO, 11*s*.). In practice, the study is an attempt to apply in British conditions some of the methods which have been developed elsewhere in the past decade or so, particularly in the United States and Canada. The British document is more than a mere academic study, however, for it is plainly intended as a theoretical justification of the decision by the Ministry of Transport to levy higher charges on heavy goods vehicles using British roads—one of the several controversial aspects of the traffic legislation with which the British Parliament is at present exercised. Indeed, there is some internal evidence that the economic argument, which is intricate enough to satisfy any taste, would have been more valuable if its authors had had more time to think about it.

The essence of the difficulty is that a road system is an integrated whole which is used as a whole by all kinds of users. The authors even use, as support for their argument, the old textbook example of how a sheep farmer cannot choose to produce wool alone, or mutton alone, but only some combination of these, but there are some readers who will ask whether there may nevertheless be a case for a less cursory examination of the economic advantages of traffic segregation. Most of the argument of the report is, however, taken up with a consideration of the various systems upon which the costs of operating roadway systems should be apportioned, and there is an air of didactic certainty about the way in which the report comes round, after much judicious consideration of other possibilities, to the view of what is called "long-run marginal cost pricing"—the impeccable principle that road users of different kinds should be saddled with that proportion of the total cost of building and maintaining the road system which is attributable to the use they make of it.

The trouble, as the report repeatedly acknowledges, is that there is an enormous gap between principle and practice. Thus in estimating the proportion of the capital expenditure on roads to be attributed to different kinds of vehicles, the ministry's argument has to rely on the rule of thumb that a heavy goods vehicle should bear twice as high a cost as a private car. Readers will be tempted to ask why this number is a better guide to good practice than the number three which the Ministry of Transport used in its evidence to the Geddes committee some years ago. Owners of heavy goods vehicles will more pertinently want to know how a calculation which involves such a large uncertainty can be used to justify an increase of about 5 per cent (£30 million a year) of the taxes levied on road users both directly and by means of fuel, especially when this increase falls exclusively on heavy goods vehicles. In the same way, there is more than a trace of arbitrariness in the way in which the ministry argues that if heavier vehicles tend to travel greater distances, there is a case for increasing the annual tax which they must pay. Is there not at least an equal case for putting up the fuel tax ?

These, however, are comparatively minor reasons for believing that the ministry has set out to design a basis for costing which is much more refined than circumstances will at present allow. The practical conclusion which is likely to be made much use of in the House of Commons in the weeks ahead is that the goods vehicles are responsible for 28·9 per cent of the cost of operating the British road system, but that they contribute only 24·8 per cent of the revenue raised from all road users. Its particular weakness is that the uncertainties of the calculation may be much greater than the difference between the two percentages. A more serious difficulty, however, is that the amount of revenue raised by taxation is roughly twice the cost of operating the road system in Britain. In circumstances like these, there is, of course, no point in seeking delicately to balance costs and receipts—and there is no serious hope of attempting to explain away the difference by vague talk about the "community cost" of air pollution and the like. The real truth is that British governments have decided to tax road transport of all kinds more heavily than costs alone would justify, and within this framework it is—and should be—a political matter to decide which kinds of road users should be let off most lightly. This, for example, is the spirit in which public service vehicles are undertaxed—and will continue to be. At a time at which the health of British industry is in everybody's mind, it would have been understandable if the Ministry of Transport had sought to reduce the costs of industrial transport. But it is, of course, well known that the ministry would like to divert some heavy road traffic to the railways (which at present cost a subsidy of nearly half the cost of running the British roads) and that is a legitimate intention if the object is really to make better use of under-used resources. And that, as it happens, would be a calculation of the kind to which the ministry's marginal costings could be much more accurately applied. In the homely language of the economists, this would not be a matter of asking sheep farmers to produce mutton and no wool, but of asking them whether they would like to produce cattle instead.

Making ESRO Ship-shape

THE European Space Research Organization is putting its house in order in preparation for the Third European Space Conference, which will take place in Bonn in June. The European Space Conference deals with the political aspects of a co-ordinated European space policy, and meets at least once a year at ministerial level. The previous meeting, at which Mr John Stonehouse, Minister of State for Technology, was Britain's principal representative, was held in Rome in July last year.

One of the outcomes of the Rome conference was that no new projects could be initiated by ESRO before the Bonn meeting, a decision expressing some dissatisfaction with the administrative and economic structure of ESRO. The new director-general of ESRO, Professor Hermann Bondi, who succeeded Professor Pierre Auger in November last year, sees as his main task the problem of getting ESRO into trim ready for the Bonn meeting. This involves the implementation of the findings of a report on the organization's structure, internal procedures and methods of work, prepared by a group of experts under the chairmanship of Mr. J. H. Bannier, a former chairman of the Council of CERN, the European nuclear research organization. The conclusions of the Bannier report included some reorganization of the managerial structure of ESRO, and the recommendation that the Council of ESRO should devote a greater proportion of its time to defining the policy and objectives of the organization. Professor Bondi is hoping that the reorganization at present under way will persuade the Bonn conference to lift the ban imposed last year.

Projects already in progress are not affected by the standstill. Three ESRO satellites are expected to be launched during 1968, and there is an extensive programme of small rocket launchings planned. A second attempt to launch the satellite ESRO-2 will be made in April—the first attempt failed because the third and fourth stages of the Scout launching rocket, fired from Vandenburg range in California, did not function. Although ESRO-2 was not placed in orbit, it transmitted signals up to eight minutes after the launch, an encouraging sign that the satellite itself was working correctly.

ESRO-1 will also be launched by a Scout rocket, probably in early October, followed in November by the launching of HEOS-A by a Delta rocket. HEOS-A will be ESRO's first satellite to be placed in a highly eccentric orbit, its purpose being the investigation of atomic particles and magnetic fields outside the magnetosphere.

Sounding rocket firings in 1968 will be based on ESRO's range at Kiruna, in northern Sweden. Most of the launchings will be from Kiruna, except four payloads which for scientific reasons cannot be launched at high latitudes. These experiments involve astronomical investigations which may be affected by auroras and studies of geophysical phenomena only observed at middle latitudes, and will be flown from a range in Sardinia.

The diverse experiments planned for the Kiruna flights include studies of auroral disturbances in the ionosphere, investigations of micrometeorites, and measurements of galactic X-rays. Perhaps the most interesting launching from the range in Sardinia will be an experiment to study the X-ray spectrum of the Sun, using a Skylark rocket fitted with a device that keeps the rocket pointing at the Sun.

Although the Rome conference recognized that a merger of the three European space organizations—ESRO, ELDO and CETS (the European Conference for Telecommunications by Satellites)—was not yet possible, a unified European space organization is likely to emerge in the future. This problem will also be receiving much of Professor Bondi's attention in 1968.

Threat to French High Energy Physics

from our Paris Correspondent

THERE are unaccustomed signs of discontent at present among the 600 French physicists who are specialists in high energy physics and who are preoccupied by the uncertainty hanging over the future of their subject. There are petitions circulating and collecting signatures, animated meetings in laboratories and a good deal of lobbying along the corridors of power. The publication next month of the report of the Consultative Committee for Research can doubtless only aggravate this state of affairs.

The twelve "wise men" (two doctors, two economists, a mathematician, a chemist, three physicists, a scientific agriculturist, a business man and a sociologist) who make up this committee responsible for advising the government departments on scientific policy were asked a year ago to furnish recommendations on the future of high energy physics. One of the important issues in this study was obviously the decision relating to the plan for a 45 GeV proton accelerator. The committee has just presented to the government a document of some 30 pages summarizing the results of its work. This report analyses the present situation and is most complimentary about the excellence of the French teams, which have, in the committee's view, assured for themselves an enviable position, particularly in CERN.

This expression of satisfaction for the men themselves is accompanied by rather more stringent comments on material resources. "French physicists, who for some time have been at an advantage by comparison with their European colleagues, now find themselves making use of more old-fashioned and generally less powerful machines." After such a preamble, the report's conclusions are extremely surprising. The committee judges, in effect, that high energy physics has for a long time benefited from a priority which, if continued, would compromise the progress of other subjects, and therefore urges that the increases of expenditure and in the number of research workers between now and 1980 should be curbed. The spending on fundamental research should be generally cut from 17·3 per cent to 15 per cent—indeed, even to 13 per cent of the research and development budget during this period—and the ceiling for expenditure on particle physics should be pegged at 5,400 million francs instead of the 6,645 million francs which was thought to be the necessary minimum sum by the working party on large accelerators. The rate of growth in the number of physicists would be limited to 3 per cent (those most concerned with the matter were asking for 5 per cent).

On the question of the 45 GeV machine, the wise men did not make any categorical statements: they are in favour of building it if it does not imperil the budgetary restrictions outlined here, which makes it something of a problem. On the other hand, the committee does emphasize the urgent need for drastic reorganization, bringing together again all the activity at present dispersed and, above all, recovering the work now under the wing of the Atomic Energy Commission.

The physicists are not unanimous in their reaction to these points, which cannot in any case be examined seriously from the point of view of France alone. The uncertainty hanging over the 300 GeV of CERN, the ambiguous attitude of Germany which had envisaged a Franco-German 45 GeV and which, tired of Paris beating about the bush, is now talking of building such an accelerator itself, has decidedly complicated the issue. However, whatever the position of the French particle physicists on the opportunity for building the 45 GeV machine and on the choice of technical solutions, they would, at all events, like the government to make a quick and clear decision. They are also surprised, and apparently justifiably so, that the question of priority from which their subject has benefited is being called into question at this point, particularly so because the committee of wise men states that the effort has been a "paying one". A change in policy will surely compromise the results so far achieved—these have already for some time been a bit precarious because of the antiquated equipment —without necessarily making certain of marked progress in other fields of research. However, "a fine sprinkling of funds" has so often been a characteristic of French research and development programmes.

Machine Minding

Next month the British Computer Society will have to decide whether to go ahead with the plan to turn itself into a professional body. The plan, put forward in June 1967, proposes that the society should become the learned institution for computer scientists, establishing four grades of membership—student, associate, member and fellow. Ultimately, admission to the society will be controlled by examination, and the society aims to do for the computer scientists what the engineering institutions have done for the engineers.

Not all the present members of the society are enthusiastic about the plan. Some say that computer science is still too young and diffuse a discipline to be easily examinable, others that experience will always be worth much more than paper qualifications. Many of the existing members of the society are computer users rather than scientists, and one member of the society compared the present efforts with a hypothetical situation in which all those who used television sets had to become qualified as electronic engineers. For all this, the plan is almost certain to be approved at the extraordinary general meeting at the end of March.

The simple reason for this is the remarkable way in which the membership of the society has increased since the plan was announced. Although the reference books list the membership of the society as 3,000, it has now reached a figure of 18,000, 10,000 of whom have joined since the new plans for the society became public knowledge. Although the secretary of the society, Mr J. G. Mackarness, sees this as evidence of general approval for the society's plans, others see it as a rush to get into the society before the examinations are established. Existing associate or ordinary members will be exempt from the examinations if they have more than seven years experience—if not, they will have to serve an apprenticeship as subscribing members until the seven years are up, when they will become members without examination. Existing student members will only have to take examinations if they are under twenty-one on May 1 this year.

In fact, the society had a problem in pitching the terms at exactly the right level. If all existing members had to take examinations—as properly they should if the society is to become as respectable as the engineering institutions—then new applicants would have been discouraged. The society admits that its reserves are "tiny", and hence needed to increase its subscription income substantially. This has been done most successfully, but possibly at the cost of losing credibility as a learned society. Moreover, subscription income will increase substantially again soon, for the rate for subscription is to double from £5 a year to £10 for members—a figure "very much in line with other professional bodies" according to Mr Mackarness, particularly as publications of the society are sent free to members. When the decision is taken at the end of March, only a fraction of the membership will be able to be present, but the rest—including those who have joined in the last year—will be able to vote by proxy.

Too Many Institutions

Undeterred by the refusal of the Institution of Heating and Ventilating Engineers to contemplate a merger with his institution, Mr H. G. Conway, president of the Institution of Mechanical Engineers, had another try on February 16. He was invited to speak at the annual dinner of another engineering institution, the Institution of Plant Engineers, and made use of the occasion to offer the plant engineers a merger with his own institution. Mr Conway was anxious not to be cast in the role of an empire builder—"My own institution has no territorial ambitions or illusions of grandeur. We presidents come and go. . . . We speak of our profession as our conscience may dictate. Some of us feel that if a few of our institutions could get together we would have benefited the engineering profession as a whole".

The terms offered for the merger are generous, and very similar to those turned down by the Institution of Heating and Ventilating Engineers (see *Nature*, **217**, 498; 1968). The plant engineers would form a divisional section with a good deal of autonomy. They could elect their own president and council, hold their own meetings and publish a journal. The alternatives, Mr Conway suggested, were either to apply for status as a chartered engineering body—which he thought unlikely to succeed, as there was a general view that the present proliferation of institutions is wrong—or become a technician body and aspire to chartered technician status.

The Institution of Plant Engineers is taking the offer quietly. It says only that it has "taken note" of Mr Conway's suggestion, which will be "carefully considered by the council of the institution", and a further statement will be made in due course. The mechanical engineers will be hoping that this time their efforts to act as a reorganization corporation for the engineering industry come off. Others, scanning the list of engineering institutions, can easily see some candidates for mergers. The Institution of Railway Signal Engineers and the Institution of Locomotive Engineers look obvious bedfellows. And it is hard to see why the Institution of Mining Engineers, which looks after coal and iron ore mining, should be a separate body from the Institution of Mining and Metallurgy, which covers mining other than coal, and metallurgy other than iron. The most improbable institution of all is the Institution of Polish Engineers in Great Britain, established in 1940. Surprisingly, it still has 500 members.

Long Short Story

The appointment at last of a new chairman to Short Brothers and Harland, the Belfast aircraft company, marks the end of an episode which has won few friends for the Ministry of Technology. Some two-thirds of the company is owned by the British Government, which therefore has an important say in its operation. In June last year, readers of the *Daily Express* and the then chairman, Mr C. E. Wrangham, in that order, discovered that Mr Wrangham was to be asked to resign his job. It seems possible that the Minister, Mr Benn, had not even met Mr Wrangham.

Air Vice-Marshal E. M. F. Grundy.

Mr Benn has not yet given the board of Short Brothers or the House of Commons a reason for his decision. In reply to six questions tabled on the matter on July 11, 1967, Mr Benn referred in the House of Commons to the substantial loss incurred by Shorts on the Belfast air freighter before Mr Wrangham's chairmanship, and the need for a reorganization to regain profitability. "This reorganization, which has already begun, can, I believe, best be carried through under the leadership of a new chairman." The ground for Mr Benn's belief, it has been suggested, was the Government's desire to see the company diversify itself out of the aircraft industry. Was it Mr Wrangham's fault that he was too successful in keeping Shorts in it? The company's troubles began in 1960 when it accepted a government order for ten Belfast aircraft in the belief that further orders would follow. None did, and the consequent loss of some £15 million made the company heavily dependent on government funds. Since that time Shorts has developed the Skyvan, a small two-engined freighter, and has built up a thriving export market for its Seacat guided missile. Substantial hopes are also placed on Blowpipe, a radar controlled guided weapon against low-flying aircraft which can be carried and operated by one man. In addition, the company has contracts for the wings of the Fokker 28 and 228 jet airliners, the engine pods for the Rolls-Royce RB 203 engines and the wing tips of the Phantom. In 1967 the company won the Queen's Award to industry.

It may be a measure of disenchantment in British industry with the Ministry's handling of the matter that it has taken until now to find a new chairman for the company. He is Air Marshal Sir Edouard Grundy, who has been managing director of Royston Instruments since 1966. Royston Instruments, which manufactured the Midas flight recorder, was a member of the Royston Group of Companies, now in liquidation. Sir Edouard has had a distinguished career in the Royal Air Force and was Controller of Guided Weapons and Electronics in the Ministry of Aviation from 1962 to 1966. His experience of the RAF, government and industry should stand him in good stead if he is to keep Shorts in business and retain Mr Benn's favour.

Beyond the Classroom

How can any institution in America now be in education and not in politics? The answer of the Dean of Harvard's Graduate School of Education is that it cannot. His report for the academic year of 1966–67 is a chilling document. The American faith in the public—that is, tax-supported and tuitionless—school is no longer justified. Urban schools are failing the "deprived" today, as suburban schools failed the "academically talented" fifteen years ago. And the Federal Government's entrance into educational reform—marked by an initial infusion of $1·2 billion in 1966—has not justified the hopes held out for it. The critics—white and Negro—are right to be disillusioned.

Even the enthusiasm which greeted the entrance of large corporations such as IBM and Time Inc. into the business of selling textbooks and making teaching machines seems to have been misplaced, according to Dr Theodore Sizer, dean of the school. Dr Sizer maintains that many of these companies have been rudely shocked. The school market is scattered and requires a large sales force; local school boards have little money for experimentation and teachers prefer to buy what is familiar. And "the gadgetry of computers and teaching machines and the rest has yielded interesting, but financially intolerable, results". Malaise has hit the education profession itself. State commissioners of education seem ready to wrest control away from the Office of Education in Washington; the private philanthropic foundations and the National Science Foundation give hints of stopping their outpourings of money into educational reforms. And the teachers themselves, underpaid—their average salary in 1966–67 was $6,820—are not only having success at becoming trade unionists but are being truculent as well. The state of American education is uneasy indeed.

Dr Sizer could almost be accused of exaggerating the darkness to accentuate the light of his own school at Harvard. It has faced the challenge pretty squarely, by accepting as a fact the proposition that much of education, and perhaps the best of it, takes place outside the classroom. The candidate for the doctorate in education can no longer expect to be trained to be a polished performer behind the desk; he must learn to be something of the street-corner social worker.

This change of direction emerged from a project called the Center for Research and Development on Educational Differences. Sustained by federal research money, various inquiries "of a scientific nature" were made into what influences determine a child's capacity to learn from formal education. One study looked into the mental abilities of six-year-olds and into the contrasting patterns possessed by children from different social classes and ethnic groups around Boston. In another project, researchers worked with Negro boys from ten to fourteen years old in one of Boston's most solidly black slums. For slightly older students, courses were offered in a variety of settings for real or potential school drop-outs, and were successful in making the boys more interested in academic achievement. The result of these and a number of other experiments was the abandonment by Harvard's Graduate School of Education of the traditional idea of its purpose—the study and improvement of instruction in the classroom—for the radical belief that education's educators must be expressly concerned with what children do and can learn outside school.

Although the interests of the school range widely—from improving the design of Boston's school buildings to improving the teaching of physics, from Boston to Minnesota and Nigeria—its primary concern has been what it offers to the postgraduate students who come to Cambridge, Massachusetts, to take higher degrees in education. The new philosophy affects them directly. One of their programmes, instead of concentrating on teaching academic subjects in classrooms, has turned training teachers into tutors, asking them to spend time with children as individuals and to follow no set curriculum. Another, the training of primary school teachers, has asked them to study a few subjects well, rather than the usual small helping of everything; this, it is hoped, will encourage more men to become teachers of the younger age group.

These steps toward revolution will be intensified in the present academic year (although the Educational Differences Center has had to be reorganized because of educational differences with the Federal Office of Education). But the aim in the future will be the same as Dean Sizer described it for the year just concluded: "to prevent the national spirit of malaise from turning in our particular community to one of negative cynicism. Schools are failing, yes; but this does not mean that they will or should always fail".

Student Participation

THE bold recommendations that students at the London School of Economics should be granted membership of its three main governing bodies create a situation unparalleled in any university or institution in Britain or, indeed, in the world. These recommendations appear in the first report on the machinery of government of the school, signed by eighteen members of a committee chaired by Lord Bridges.

The need for changes in the way in which LSE is governed has become increasingly obvious over the past few years, as a result of the growth of the school and the complexity of its activities. This need was first seen in August 1966 when Sir Sydney Caine presented specific proposals in a paper circulated to the Court of Governors and to the academic bodies in the school. On February 2, 1967, the Court of Governors agreed to establish a joint committee consisting of members of court and the academic body, and five student members were added to this committee.

The main object of student participation, the report says, is to secure student co-operation, thereby strengthening the unity of the school. It may also help to make accurate information on the school's activities available to all students. There are two ways in which students' participation could be achieved: by "consultation" which would need to be official, involving the establishment of joint student–staff consultative committees which would meet regularly to consider in advance matters on the agenda; the alternative scheme would involve the election or nomination of appropriately qualified students to serve as members of committees or other bodies. Of these two, the committee decided that "membership" would be most advantageous.

Many of the recommendations follow the general proposals of Sir Sydney Caine's memorandum. The report recommends that there should be about sixty members of court, including twelve members of academic staff and four to eight student members. A council should be established to replace the existing Standing Committee as the central budgetary authority of the school, and it is proposed that three members of the council should be students. The committee recommends that a senate be established to have executive powers in academic matters, and that it should include five student members. Students will not be allowed, however, to become members of the Academic Board—the forum through which all teachers would discuss and be asked to endorse important issues of policy. In addition, students would be members of some fourteen sub-committees of the senate and council, but staff appointments and promotions would be made by committees other than those on which students are members.

A minority report presented by two student members, Mr Dick Atkinson and Mr David Adelstein, lists a number of criticisms of the majority report. In the introductory comment, it is suggested that this report has limited itself to "managerially specified problems" and ignored "contemporary educational matters". In addition to challenging the assumptions and limitations of the report, Mr Atkinson and Mr Adelstein suggest a number of alternative proposals. For example, they consider that the court should comprise forty representatives of "society", including persons in trade unions, the theatre, the professions, peers of the realm and others. Furthermore, they suggest that the court should be assisted in its functions by electing a committee consisting of three governors, three staff and three students, all of whom should be members of court.

Academic Awards

CONTINUING success is reported by the Council for National Academic Awards (CNAA) in its third annual report covering the period up to September 1967. Initial misgivings about the success of the council are not confirmed by figures of the student enrolments for 1966 to 1967—26 per cent more students enrolled for courses leading to the council's first degrees in September 1967, compared with the number in 1966. The 1967 figure is 167 per cent more than that for 1965. The total number of students attending CNAA courses this session is 10,687, compared with 7,109 at the same time last year.

During 1966–67 the council approved fifty-four courses out of 136 proposed by colleges. Of the courses approved, forty-seven were in science and technology (50 per cent of the number considered) and seven in arts and social studies (17 per cent of the number considered). There are now 173 courses recognized by the council (as at September 1967) covering subjects ranging from aeronautical engineering, agricultural engineering, to textile technology and urban and regional planning. Most are sandwich courses—77 per cent of the courses in science and technology are of this type. One new course, of particular interest to some, is a part-time day and evening course in mathematics at Hatfield College of Technology which is designed especially for mature students.

A useful feature of the CNAA courses is that some are in fields where there are few or no courses in universities; degrees can now be obtained, for example, in building economics, estate management, food science, and photographic technology. The council also reports that it is considering librarianship and architecture as suitable fields for CNAA degrees. Since the report was written it is understood that a degree in information science has been approved by the council. It is to be offered by the Department of Librarianship at Newcastle College of Commerce as from September 1968. This course is designed primarily to prepare students to work in governmental and industrial information departments.

It is easy to forget that the council also has the power to award higher degrees. During 1966–67, five courses leading to the council's M.Sc. degree were approved, bringing the total number of CNAA postgraduate courses to seven—fifty-three students are enrolled on these. Two of the courses offered are in corrosion science and engineering and in experimental nuclear physics.

There is a growing number of registrations for the council's research degrees, particularly from candidates in research organizations. The flexibility of the council's arrangements, and the absence of a residential requirement, seem to be proving attractive to many candidates not eligible for higher degrees awarded by universities. The council's Ph.D. degree or M.C.T. (Membership of the College of Technologists) was awarded to twelve students during 1966–67. There are now 317 candidates registered for research degrees.

The council reports continuing good relations with the universities. Many organizations and professional bodies now give CNAA degrees the same recognition as they give to university degrees; for example, the Civil Service in its recruitment policies, and the Burnham committees in their acceptance of graduate qualifications for salary purposes.

It is inevitable that the council's activities are inseparable from the development of the polytechnics. In this connexion the council is continuing its efforts for new types of course, and broader courses combining more than one discipline—courses covering science and technology and social studies, which might be attractive to students who have read arts subjects in the sixth form at school.

Visiting Fellows

The Senior Visiting Fellowship scheme of the Science Research Council is undergoing spring cleaning, and the revised regulations are likely to be published in the near future. As it stands at the moment, "the council will make grants to applicants of acknowledged standing to invite senior scientists of distinction in other research schools in this country or abroad to the investigator's institution as senior visiting fellows for a period not exceeding one year to give full-time advice and assistance to the investigator in the field in which the visitors are eminent". The fellowships were designed to bring expert outsiders into individual research projects when specific advice was required, and are therefore included in the research grant scheme. Despite criticism on this score, and suggestions that the visiting fellows should be treated in the same way as research fellows, it is unlikely that the new regulations will alter the grouping of the schemes.

People like Dr N. Kurti of Oxford are enthusiastic about the possibilities of such a scheme, but regret that it has not received more publicity. Another criticism has been raised over the question of pay, because, as the regulations state, "if contributions to salary or expenses are being made by a senior visiting fellow's parent organization or other body, the charges to the grant will be reduced accordingly". This is thought to be an unfortunate arrangement, particularly for American visitors whose salary is paid on a nine-monthly basis but is considered to cover a year.

Until now, applications for senior visiting fellowships have had to be made on the same complicated forms as those for research grants. But here the criticism seems to have had some effect and the tidying up of the scheme will probably result in a shorter form being produced. It is thought unlikely that the improved scheme will be put before the council itself, which indicates that there is little hope for major changes. Mr L. S. Smith of the SRC has already stated that there will be no increase in the daily allowance for senior visiting fellows. During the year 1965–66, the last year for which figures are available, the council spent £42,645 on fifty senior visiting fellowships—a reduction of more than £13,000 compared with the year before.

Changes at Cold Spring Harbor

The Cold Spring Harbor Laboratory for Quantitative Biology, famous for its annual symposia, its summer courses and for its year-round research in genetics, has recently been strengthened by the appointment of Dr J. D. Watson as director from February 1 of this year. Dr Watson seems to have been persuaded to take on the job, while remaining as Professor of Biochemistry and Molecular Biology at Harvard, by his wish to see that the laboratory's dramatic improvement from a state of financial and physical bankruptcy would not come to a halt now that Dr John Cairns, the current director, had chosen to concentrate once again on research. Dr Cairns, who before his appointment to Cold Spring Harbor had made some elegant autoradiographical studies of DNA duplication, found on his arrival in Cold Spring Harbor an institution entirely without money, some $80,000 in debt and with physical plant requiring at least $1,000,000 for restoration to a first-class condition. Over the past five years, Cairns has worked heroically; now much of the laboratory has a strikingly pleasant appearance, and the cash reserves are up to $125,000. But after five years of this, Cairns naturally wishes to return to his scientific career.

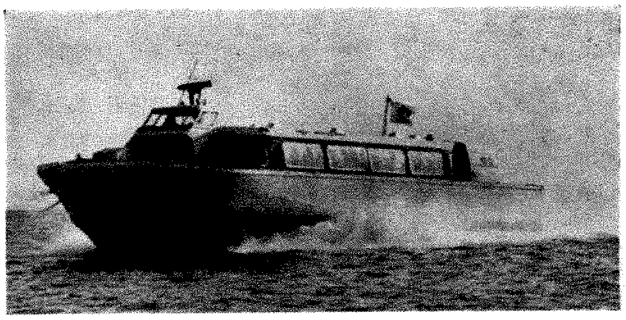
Dr J. D. Watson

The appointment of Dr Watson, already closely connected with the laboratory as a member of the Board of Trustees, and a frequent summer visitor since 1948, should allow a smooth administrative transition. He and Dr Cairns have worked closely together over the past few years, and one of Dr Watson's first aims as director will be to find an endowment for the secure backing of Dr Cairns's position as a staff member. Other immediate objectives will be to find capital funds for a new library to house Cold Spring Harbor's extensive collection of genetic literature, additional summer housing for an enlarged summer course programme and a new laboratory building for expansion of research into the area of molecular biology of higher cells, in particular the multiplication of viruses capable of causing tumours.

Another Hovercraft

Hovermarine, a small firm based in Southampton, has now produced its first hovercraft, the HM 2, on licence from Hovercraft Development, Ltd., which handles the patents for the National Research Development Corporation. The design is particularly interesting; the hovercraft has submerged sidewalls, so that in motion it looks much like a conventional boat (see picture).

The makers suggest that this sort of craft will be best suited to use in estuaries or rivers, where very large seas are not often experienced. At a speed of 28 knots, the craft will comfortably accommodate seas of up to 3 ft. in height; in more severe conditions, the company says, the maximum speed attainable will depend on the state of the sea and the amount of discomfort which the passengers are prepared to accept. When hovering, as in the picture, the sidewalls of the craft act as twin keels, giving the craft good directional stability. Shrewdly, Hovermarine says that this will make it possible for operators to pay realistic wage rates to the helmsmen, instead of having to employ skilled pilots. The craft will carry sixty passengers, or sixty-five at full stretch, and costs about £70,000.



The Hovermarine HM 2 on trials.

In contrast with other hovercraft designs, the Hovermarine HM 2 should be reasonably quiet in operation. It is driven by twin submerged marine screws and not by aircraft-type propellers. Motive power is supplied by two Cummins lightweight diesel engines, and the hover power is supplied by another Cummins engine. The hull is made of glass fibre-reinforced plastics, and the craft can be used from conventional jetties and quays. Hovermarine's own calculations, unsupported as yet by any statistics from operators, show that, at a load factor of 50 per cent and an average speed of 30 knots, operators could make a profit if fares were charged at the rate of 6*d*. a mile. Fares of 9*d*. a mile would produce an annual profit of £25,000 on the same assumptions, if the craft were depreciated to 10 per cent residual value in 10 years.

Research on Foreign Languages

In spite of two British applications to join the European Economic Community, British people remain conspicuously slow at learning foreign languages. There are, however, some signs of impending change, according to the first report of the Committee on Research and Development in Foreign Languages (HMSO, 5*s*.), which was set up in 1964 under the sponsorship of the Nuffield Foundation, the University Grants Committee, the British Council and what is now the Confederation of British Industry to co-ordinate research and development and to spend a little money—mostly other people's. The chairman is Dr L. Farrer-Brown, a former director of the Nuffield Foundation.

The committee's first experiment was with the teaching of French in primary schools. It has been helped particularly by a pilot scheme begun by the Nuffield Foundation in 1963 which is intended to discover whether a modern language can become a normal part of the primary school curriculum. The report says quite frankly that there are many questions yet to be answered—what is the best starting age ? How much time should be devoted to foreign languages at these tender ages ? Are specialists necessary or can ordinary class teachers manage ? What is the effect of teaching French on the general performance of the pupils in primary schools ? The answers to some of these questions may emerge when the National

Foundation for Educational Research has finished its programme of evaluation.

Teaching languages at ordinary level (up to 16) has risen considerably during the past twenty years: the number of pupils offering Russian, for example, has increased nearly 600-fold. If the first modern language can be started in primary schools, it is hoped that more pupils will take a second modern language in secondary schools. Emphasis is now being laid on teaching the spoken language.

The growth of French teaching in primary schools has also led to a conspicuous growth of courses in colleges of education, and a handbook prepared in 1966 showed that French could be studied in 81 colleges. In recent years, language courses have also increased in further education, and it seems that some of the most successful courses have been those provided in direct response to an approach from a firm or firms in the area. Several universities now provide for the study and teaching of languages in new ways: for example, the report points out that in some universities the study and teaching of languages are linked with the study of linguistics, either within a unified centre or in a separate department.

New IBP Chairman

Dr W. Franklin Blair, professor of zoology at the University of Texas, has been appointed chairman of the United States National Committee for the International Biological Programme (IBP). He succeeds Dr Roger Revelle, director of the Center for Population Studies at Harvard University. Dr Revelle was appointed chairman at the beginning of the three-year planning period for the IBP in 1964. Now that the IBP has moved into its five-year operational stage, Dr Revelle will act in an advisory capacity only, because of his commitments at Harvard and the National Academy of Sciences. Dr Revelle was recently appointed chairman of the academy's Science Organization Development Board and now acts, in effect, as Deputy Foreign Secretary of the Academy.

Dr Blair has been associated with the United States IBP programme from its beginning. One of his positions has been as co-chairman of the Subcommittee on Environmental Physiology. He has also organized the IBP integrated research programme on Convergent and Divergent Evolution. His main interest is vertebrate biology, particularly population genetics and the ecology and speciation of mammals, reptiles and amphibians.

Drugs in School

Drug dependence in young people under eighteen years of age in the City of Westminster has recently been investigated by a social worker under Dr J. H. Briscoe-Smith, medical officer of health for the area. The investigation, started in February 1966, was prompted because it was felt that the Health Department should have as much information as possible on the extent of the problem in the Westminster area, particularly as Soho lies within the city's bounds.

Much of the report seems to state the obvious, but it does at least prepare the ground for more extensive research. The aims of the survey were to estimate the size of the problem, whether gaps exist in the provision at present made and to see how local authorities might help. Of the fifteen head teachers of secondary schools interviewed, nine had experienced problems with pill taking by children in their schools. While about half the teachers felt that many of the young people in the fourth and fifth forms experimented with pills at some time, the others considered that this was a pattern pursued by only a small minority. It does seem, however, that the problem is more serious in schools in the "old" City of Westminster. It is also known that there are a number of young heroin addicts around Victoria Station and a number of boys who were known to be taking pills at school in the Westminster area are now heroin addicts.

Of nine youth clubs investigated, six of the larger ones reported a drug problem although it was only a slight one in three of them. Between April 1965 and April 1967, 74 young people were convicted at the Westminster Juvenile Court on charges of possessing drugs, but of these only eight were residents in the area. As the report emphasizes, this is complicated by young people passing in and out of the area, which is in the centre of London.

On the whole, head teachers were against lectures on prevention because they felt that this might draw attention to drug taking and thereby create a challenge for young people. Instead, they thought that lectures for parents might be a better idea. Most schools felt that teachers would welcome more practical information on the matter and a book is to be published later this year containing coloured photographs of pills to enable teachers to recognize them. Four Rotary clubs in the Westminster area are hoping to set up an advice centre for drug addicts, and the Men's Social Services Branch of the Salvation Army is providing a hostel for young boys on probation for drug charges. By setting up an information service, it is suggested in the report that this might assist other workers in the field such as general practitioners and probation officers. A social work service offered by the Health Department to help people with problems of drug dependency is also suggested.

On the Nature Trail

Owners of land in Britain with areas of natural history interest should read *Nature Trails*, a handbook produced by the Nature Conservancy (distributed by Frederick Warne, Ltd., 5*s*.). This gives advice on the setting up of nature trails—the routes along which visitors can walk, with information provided by signs, posters, pamphlets and sometimes guides.

The first nature trail was set up in 1961, many more were instituted at the time of National Nature Week in 1963, and there are now about ninety of them. Some have been set up on national nature reserves by the Nature Conservancy; the Forestry Commission has some and others have been opened by county naturalist trusts and by private organizations and individuals. (A list of more than eighty nature trails can be obtained for 2*s*. from the Council for Nature.)

Where a good guide is available—and the handbook points out that a bad guide is worse than no guide at all—the tour can be varied according to ecological changes or the interests of the visitors. On the whole, a shortage of manpower makes guided trails rare; more common are the trails for which a pamphlet describes points which refer to numbered stakes found at intervals along the route, which is marked out by arrows and signs There may be displays giving further information about the important features of the environment At Gibraltar Point Local Nature Reserve, in Lincolnshire, there is an information centre where voluntary wardens answer questions at the weekends

At Alvecote Pools the National Coal Board has leased a disused Methodist chapel to the West Midlands Trust for Nature, and this has been equipped as a day centre, supervised by a committee of local teachers It is used regularly by about twenty-five schools in the area Nature trails are clearly very valuable as a supplement to biology lessons The handbook points out that, although the trails are chiefly a teaching aid for younger children, they can help to illustrate and clarify examination syllabuses such as advanced level botany Plant identification and taxonomy can certainly be made more real, but whether they can be taught painlessly, as the handbook claims, is less certain

A Catalogue of Earthquakes

The International Seismological Centre in Edinburgh is beginning to fulfil what it sees as its main function, the publication of a regional catalogue of earthquakes The centre, formed in 1963, last year issued its first regional catalogue, which listed earthquakes for the first six months of 1964 The catalogue is based on readings from a global network of 612 stations, and lists nearly 5,000 events thought to be earthquakes, arranged according to the geographical region in which they occurred. In addition, the catalogue contains details of 186 known or probable explosions, data which can be useful for the calibration of seismographs

Computer processing of the raw data is essential for cataloguing work of this kind, but computer programmes are remarkably prone to teething troubles, and these seem to be the main reason for the 3½ year delay in publication Some time lag is inevitable, it seems, because of the inaccessibility of many earthquake recording stations, and the time the data take to reach Edinburgh Because the catalogue is intended to be a final record, replacing preliminary results published only months after the events, data from remote stations, some in the Antarctic, are included

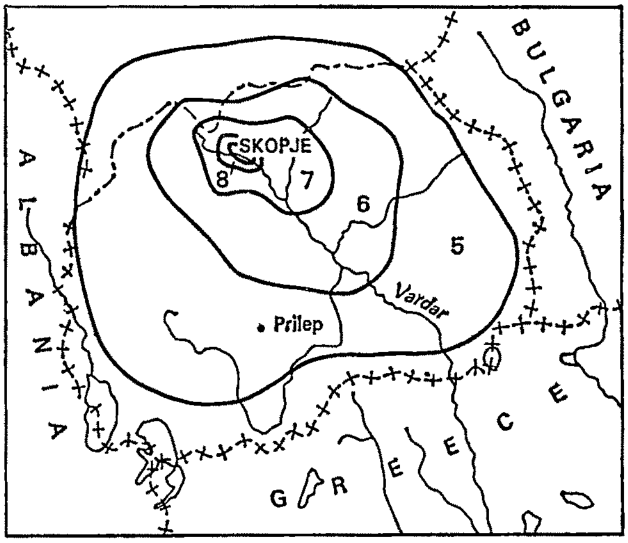
The director of the centre, Dr P. L Willmore, is hoping to cut down the delay in publication to two years or eighteen months, now that the initial difficulties have been ironed out Once the influx of data is under control and the catalogue brought up to date, the ISC expects to find time to analyse records from before 1964 and to produce catalogues of earthquakes occurring in the 1950s

The most rapid publication of preliminary seismic observations and determinations of the epicentre of earthquakes is the province of the United States Coast and Geodetic Survey These reports are especially useful to relief expeditions dispatched to assist at earthquake disasters where local lines of communication have been destroyed In such cases, the times and locations at which shocks occurred can be invaluable

On the other hand, catalogues like that produced by the International Seismological Centre find their main application in long-term statistical investigations of earthquakes Designers of large-scale structures which are especially prone to earthquakes—dams and tall office blocks, for example—like to know how susceptible the area they are building in is to earthquakes Here the regional catalogue of earthquakes will help.

Skopje Earthquake

After the earthquake in Skopje on July 26, 1963, the government of Yugoslavia decided to investigate the causes and effects of the earthquake damage, so that the city could be rebuilt with better resistance to the stresses of any future earthquake As well as calling in Yugoslavian scientists and engineers, the government sent a request to UNESCO for experts to advise them The findings of these four investigators have now been published (UNESCO, 51*s*)



Distribution of observed intensities for earthquake on July 26, 1963 (compiled by D Hadzievski and A Zátopek)

Mr J Despeyroux, chief engineer of SOCOTEC in Paris, reported on building problems and Dr N N Ambrayseys of Imperial College produced an engineering seismology study of the earthquake It was concluded that there would be no point in moving the city completely, but if new building developments are spread out around the city the risk will be minimized In replanning the old city wide streets can be included to give good access to the centre Special building codes for earthquake resistant structures are advisable, and controlled quality of structural materials, about which builders should be informed, would increase the safety of permanent buildings Thirty per cent of the most important buildings in the city were left intact or were not irreparably damaged, those which were properly designed and constructed being the best survivors Regulation of the River Vardar is important because it affects the seismic quality of the ground Earthquake engineering and seismology are different, although related, subjects, and the former is neglected Dr Ambrayseys suggests that a school should be set up in Skopje to train engineers and architects to postgraduate level in earthquake engineering, geotectonics and seismology It would be the first of its kind in Europe

Dr A Zátopek from Czechoslovakia, an expert in seismology, assembled and analysed macro- and microseismic data with the conclusion that the epicentral intensity was IX MCS and the focal depth 5 km at Skopje, the epicentre In all, the shaken area covered 105 km^2 The earthquake was described in general terms as a superficial or shallow tectonic, composed of several shocks, with typical small block structure mechanism within the epicentral area Dr Zátopek recommended that there should be detailed studies of the seismology of Yugoslavia

The final part of the report was produced by Dr A A Sorsky of the University of Moscow, who studied the geological and tectonic factors of the 1963 earthquake His conclusions include the fact that Skopje is on a seismologically dangerous area, and earthquakes are liable to occur there again Seismological and geological data are being collected by Yugoslav scientists so that a microregionalization map can be compiled, from which can be worked out the areas of most movement and consequently most seismological danger Provided building sites are chosen according to this map, Dr Sorsky believes that building should continue on the present site of the city

Keeping Physicists Aware

Comparatively recently there has emerged a new type of indexing journal, aimed at alerting readers quickly to titles of papers written in their respective fields In their simplest form, current awareness journals, as they are called, consist of a collection of facsimile reproductions of contents tables of individual journals The weekly list, *Current Contents*, published by the Institute for Scientific Information, Philadelphia, since 1958, is a well known example of a journal of this type The Polish Academy of Sciences produces a similar key to the Polish literature A more sophisticated example of a current title index is provided by the semi-monthly *Chemical Titles*, a product of the Chemical Abstracts service, which is a computer produced keyword index

In January 1966, the Institution of Electrical Engineers (IEE), in association with the American Institute of Physics (AIP), inaugurated a new current awareness journal called *Current Papers in Physics* to be used in conjunction with *Physics Abstracts* produced by the same institutions The IEE also publishes two other current awareness journals, *Current Papers on Control* and *Current Papers in Electrotechnology*, and two other abstract journals, *Control Abstracts* and *Electrical and Electronics Abstracts*—together the journals are known as INSPEC (Information Service in Physics, Electrotechnology and Control)

It was decided, before *Current Papers in Physics* (*CPP*) began publication, that it would be sensible to assess the need for this new journal and its usefulness During its first year of publication (1966) a joint study was therefore undertaken in Britain by the Aslib Research Department for the IEE and in the United States by the then Documentation Research Project staff of AIP The first report of this study has recently been published (*Results of Questionnaire on Current Awareness Methods used by Physicists prior to Publication of "Current Papers in Physics"*) Panels of physicists were set up in Britain (268 physicists) and the United States (682 physicists) Before *CPP* appeared, the panel members received the first of a series of three tests This initial questionnaire covered panel composition, methods used by physicists to keep up to date before *CPP*, and expectations of a current awareness journal in the field of physics Results of this questionnaire are given in this report Two later questionnaires covered physicists' comments on *CPP* and suggested improvements, and a record of the actual use made of the publication and the order in which sections were scanned Reports of these studies are to be published later

The results of the first survey show that current awareness journals were not much used by panel members before *CPP* appeared In general, the use tended to follow the pattern of the country of publication The journals published in the UK—*British Technology Index* and *Current Papers for the Professional Electrical and Electronics Engineer* (now *Current Papers in Electrotechnology*) were more used in the UK than in the US, and the reverse was true for the US physicists in terms of *Chemical Titles*, *Current Contents · Physical Sciences*, for example. Physicists co-operating in the study seemed to rely mainly on scanning current issues of journals as a means of keeping up to date before *CPP* It was thought to be the best method by 36 per cent of the British physicists, while 37 per cent of United States physicists ranked this method in first place The physicists indicated, however, that they would welcome a publication that would relieve them of the chore of actually scanning journals, provided that "nothing relevant" was missed There were various constructive suggestions about the requirements of a current awareness journal, and also comments about available abstract journals The IEE must be satisfied with the discovery that *Physics Abstracts* was the most widely used publication in the field, in both Britain and the United States. As the report puts it, "the heavy usage of this existing IEE publication in physics augurs well for the success of a complementary current awareness journal from the same publishers" The next two reports may well show if this is indeed the case. At the moment the IEE appears to be satisfied with the sale of *CPP* in Britain and in the United States

Fish Farming

Fish farming has been shown to be practicable, but the "rate at which the prospects are converted into reality will depend critically on the research effort we are able to mount" This was the conclusion of Dr H A Cole, Director of Fishery Research at Lowestoft, who addressed the Royal Society of Arts last week on the artificial cultivation of sea and shell fish and described the research which must be done before a successful intensive rearing system can be built There must be "systematic optimization of the environmental factors present in the system followed by scientific breeding to provide animals highly adapted to culture conditions"

The depletion of fish supplies accessible to British fishermen has led to the investigation of alternative sources, and to the realization that artificial cultivation can lead to advantages in processing and marketing, with possibilities for export Plaice was one of the first fish to be investigated, 15 years ago, and much has been learned from rearing young plaice in tanks and ponds from eggs collected at sea The best conditions of temperature, salinity, light, water exchange and quantity of food have been investigated for plaice As a result 400,000 were produced in 1965 until they were large enough to take to the bottom of the sea as adult flat-fish In the future, however, it is likely that sole will be cultivated more widely than plaice, as it is more valuable, the young grow readily and the adults adapt to tank life and can be induced to spawn This fish favours a warm temperature and is therefore suitable for cultivation in the heated sea water which is put out by power stations Dr Cole suggested that within ten years sole production at these power station sites will be in full swing, and turbot and brill are likely candidates for the same treatment Some shellfish also need warm water and can be grown in these warm water wastes

Oysters of the *Ostrea edulis* variety were once common in estuaries around Britain, but successive pests and floods have reduced the breeding stock to such an extent that any recovery of the oyster industry will depend on successful artificial rearing Fifty years of slow but steady progress in artificial breeding at Conway led to commercial scale techniques being used four years ago and a commercial hatchery now being built in South Devon is likely to produce a steady supply of young oysters New Zealand and Japanese oysters are being investigated, as are American clams The latter can be planted on the shore at the age of 1–1½ years, but must be protected from crabs by plastic mesh until they grow to an inch in diameter. After four years they are large enough to be marketable

The English prawn is another suitable species for artificial cultivation, despite its cannibalistic tendencies, and a habit for producing eggs rather than getting fat As with all other artificially reared fish, the feeding problem for shrimps has yet to be completely solved The brine shrimp *Artemia* is a useful food source for many kinds of fish, but attempts are being made to produce a protein based artificial food Waste fish flesh and poultry offal may provide the basis of the substance, which must be soft Attempts are also being made to find a palatable fish which is herbivorous Grey mullets and the freshwater *Tilapia* are two possibilities, but as yet there is little demand for these varieties

Parliament in Britain

Nationalized Industry Research

The programmes of the National Coal Board provide for estimated expenditure on research and development in the current financial year of £5 million The Gas Council and Boards will spend £5,650,000, and the Electricity Council and Boards £10,650,000 The National Coal Board in 1966 employed 356 qualified staff on research and development, and the Gas Council and Boards 340, in the current year the Electricity Council and Boards employed about 900 The figures were given by Lord Winterbottom concluding a debate for the Government on February 14

Atomic Energy Authority

Dr J Bray, Joint Parliamentary Secretary, Ministry of Technology, stated that the Atomic Energy Authority aimed to achieve cuts of £3 5 million in 1968–69 in the cost of their civil research and development programme principally by some reduction in capital expenditure and by some run down of manpower The balance of the cut would be met by limiting extramural research and development contracts The effect of the cut of £6 million in 1969–70 was still being studied by the authority (Written answer, February 12)

Scientific Officers

The Minister of Technology, Mr A Wedgwood Benn, gave the average age on January 1, 1968, of officers in each grade of the scientific officer class employed in the Ministry's Research and Development Establishments as chief scientific officer, 52, deputy chief scientific officer, 50, senior principal scientific officer, 47, principal scientific officer, 45, senior scientific officer, 33, and scientific officer, 26 The Minister of Defence for Administration, Mr G W Reynolds, gave the corresponding figures for scientific officers in the Ministry of Defence's establishments 54, 45, 48, 46, 36, 26 (Written answers, February 12)

Chemical Defence

The Minister of Defence for Equipment, Mr R Mason, stated that the work of the Chemical Defence Experimental Establishment was directed towards research on defence against chemical warfare, but some of the work of the establishment had found applications in medical science Such benefits included the investigation of the mode of action of several toxic compounds leading to the development of measures for treating intoxication, the development of an antidote to poisoning by organophosphorus insecticides (a service providing advice and first-aid treatment had been maintained since 1960), the development of aids to therapy, such as an automatic injection device and a portable resuscitator which is used by fire brigades and other rescue services, the investigation of the structure of the skin and the processes of skin penetration, and the investigation of the nature of the alveolar lining of the lung Mr Mason later gave the number of qualified engineers and scientists working in defence research and development establishments on December 31, 1967, as 2,838 compared with 2,612 on December 31, 1964 (Written answers, February 13 and 14)

Protein from Leaves

Mrs Shirley Williams, Minister of State at the Department of Education and Science, stated that the Rothamsted Experimental Station is carrying out research on the extraction of protein from the leaves of crop plants Figures for the extractability of leaf (including tree-leaf) protein from many parts of the world were now being published These were not strictly comparable because of differences in the techniques of grinding and pressing Measurements of the extractability of protein from local crops were an essential prelude to any attempt to make leaf protein for use as a food in regions of protein deficiency Unexpected differences had been found in the nutritional value of protein preparations The effects of variations in the technique of precipitation, filtering and processing or drying the protein would be studied and the National Institute for Research in Dairying and the Rowett Research Institute would co-operate in measuring the nutritional value of some of these products (Written answer, February 13)

NEWS AND VIEWS

Accelerators for the Seventies?

HIGH-ENERGY physicists are almost as dismayed as the governments which support them by the high costs of making particle accelerators, which is a part of the reason why there is at present great interest in the kinds of accelerators called collective ion accelerators On the face of things there is at least a possibility that this new technique may eventually lead to the design of simpler and even cheaper particle accelerators To be sure, there is not the slightest prospect that collective ion accelerators will allow European governments to shelve the awkward question of whether or not to contribute towards the 300 GeV accelerator that Cern is anxious to build At this stage, indeed, nobody can be sure that schemes like these can ever justify the enthusiasm which they have stimulated in many places By all accounts, however, the symposium on the subject at Berkeley the week before last showed that these developments are too valuable to be ignored

The new proposals turn on the way in which, in the presence of a sufficiently strong magnetic field, it is possible to embed large numbers of protons in an organized cloud which consists of a still larger number of electrons Doing this is simple enough, given the availability of some of the techniques which have come into fashion in plasma physics A toroidal ring of 10^{13} electrons with linear dimensions of the order of a metre can be loaded with protons simply by the intervention of hydrogen gas It seems usually to be assumed that there will be one proton for every hundred electrons or so The large ring can then be contracted into a more manageable one a few centimetres across, and the result is an electrified object, a charge to mass ratio which is for practical purposes the same as that of an electron—with the understanding that the mass is the relativistic mass of the electrons moving within the torus, possibly with an energy of 20 MeV or so The result is that, when an electron lump like this is stripped of its electrons—which is, by all accounts, all too easy to accomplish—the protons which are left have individual energies which are greater than those which would have been acquired by electrons in the same circumstances in the ratio of the mass of the proton to that of the relativistic electrons within the lump—a factor of forty or thereabouts

The first practical suggestion for using these electrified objects as fodder for a linear accelerator seems to have been made by the Russian group at Dubna, which described some of its ideas at a conference of techniques for particle accelerators at the Massachusetts Institute of Technology last September The notion seems to have been taken up with great enthusiasm, particularly at Berkeley, still then mourning the loss of its scheme for a 200 GeV proton synchrotron to Weston in Illinois The recent symposium there was preceded by a working party which spent two weeks on detailed discussion of possible realizations of the principle, and which seems to have confirmed the mood of watchful optimism which prevailed before Thus it does appear that it should be possible to accelerate electron lumps along the axis of a linear accelerator in such a way as to give the protons which they contain about 1 MeV of energy for each centimetre length, which is a handsome promise On the other side of the balance sheet, however, are several snags The meeting at Berkeley has, for example, drawn attention to the very large amounts of power that would be needed to keep an accelerating machine in operation There are also potential problems in the maintenance of a magnetic field along the axis of the accelerator And potential users of machines like this are quick to point out that pulses of fast particles which last for a nanosecond or thereabouts would not bring much joy to those among the conventional machine builders who spend much of their time seeking ways of flattening the much longer pulses of particles which are now available from accelerating machines so as to make more efficient use of them Clearly there is a great deal to be done before anybody will be able to face any government with a request for money

How Immortal are Amoebae?

from our Microbiology Correspondent

ONE of the most intriguing questions posed to biologists concerns the life span of cells and how this defined period of viability is controlled Data are accumulating on the differential life spans of cells in animal bodies and, in a few instances, this conclusion is being corroborated by studies of animal cell cultures Hayflick (*Exp Cell Res*, **37**, 614, 1965), for example, showed that human foetal lung cells had a life span equivalent to a doubling potential of 50 ± 10, whereas cell lines derived from adult lung had a significantly lower doubling potential The presence of a latent virus, mycoplasma or the nature of the growth medium did not account for this finite life-time

For a number of years, Danielli has been investigating the life span phenomenon in *Amoeba* Clones of *A proteus* and *A discoides* were reported to have apparent immortality when cultured with an unlimited supply of *Tetrahymena* as food organism, but after a period of culture on maintenance diet a defined life span was induced Further analysis of the "immortal" and "spanned" states in *A proteus* has been directed towards elucidating the control of this switch phenomenon (Muggleton and Danielli, *Exp Cell Res*, **49**, 116, 1968) and transplantation experiments have allowed some assessment of the roles of the nucleus and cytoplasm Muggleton and Danielli found earlier that spanned amoebae exhibited two behavioural patterns following division In the first, type *A*, stemline growth occurred in which one product of binary fission showed early mortality while the second daughter cell underwent disparate division again This sequence continued for a finite period and was followed by death of both daughter cells In contrast, division of type *B* cells produced two viable daughters which resulted in exponential growth until such time as all cells of the clone died When an immortal or normal nucleus was implanted into spanned cytoplasm, all the amoebae were spanned and, moreover, all were converted to type *B* behaviour regardless of whether the recipient cytoplasm was type *A* or *B* Transfer of a spanned nucleus to a normal cytoplasm, however, produced type *A* spanned amoebae One conclusion here is that a spanned nucleus normally confers stemline behaviour on its descendants, while a spanned cytoplasm normally induces an exponential growth pattern Small injections of spanned cytoplasm into normal amoebae also induced a finite life span in the recipient and a similar effect followed injections of cytoplasmic supernatant from spanned amoebae So far, conversions have been in one direction only, and Muggleton and Danielli have been unable to convert amoebae from the spanned state to the immortal state Finer analysis of this system is an exciting prospect In particular, the bimodal behaviour of spanned clones is indicative of a complex "spanning" phenomenon Cell life span itself may be under the control of a higher order mechanism, with which we are not yet familiar, or may be the resultant of an accumulation of errors in DNA replication which inactivates part of the genome This latter may be analogous to the "fault-load" hypothesis of Szilard or Hayflick's proposed "multi-hit, multi-target" phenomenon

Flow of Blood

from a Correspondent

A SYMPOSIUM on Haemorheology and the Microcirculation was held at the Royal College of Surgeons on February 10, under the joint sponsorship of the British Society of Rheology and the British Microcirculation Society

Undoubtedly the main contribution was in the field of the biophysics of blood flow in the smallest vessels The mathematics involved was usually simplified for the benefit of the members of the audience who were principally concerned with practical applications to clinical diseases, but the solution of the equations involved often required the use of a computer M J Lighthill provided an analysis of the behaviour of a deformable pellet, such as a blood cell, which has a resting maximum diameter just too large for it to pass through a small tube, such as a capillary, without deformation He predicted the existence of a thick film in which there must be a substantial leak-back from one "bolus" to another If the velocity is reduced, such a film becomes very thin so that the red cell's motion temporarily "sticks" or "seizes up". This type of behaviour may often be observed in the smallest capillaries in the living circulation, but it does not account for the deformations of the cells that are recorded by high speed photography S R Montgomery described the behaviour of large simple rigid models of the shape of resting red cells and showed that their motion is essentially unstable unless "pores" are made in their centre corresponding to about one-tenth of their leading surface area A mathematical analysis of pulsating flow was provided by J H Gerrard in the case of flow driven by simple pistons In these circumstances the axial velocity is less than that nearer the wall of the tube E W J Mardles examined the behaviour of simple liquids containing a meniscus, flowing at very low shear rates in narrow channels, and showed that the resistance of this meniscus must be very great if the channel is less than 10 microns in diameter Although this is the mean diameter of the larger capillaries, it is not yet certain how these conclusions, which might apply to the plasma, would also apply to the blood cells It has been suggested that fibrinogen in the plasma is responsible for giving whole blood its non-Newtonian characteristics, but D N Walder, J P A Weaver and A Evans, using a cone-and-plate viscometer, showed that the wide range of variations in fibrinogen level that normally occurs in patients with different diseases does not seem to have any physiological effect except perhaps at very low shear rates, discussion on this was controversial The effect of cryoglobulins in human plasma was discussed by R B Whittington and J Harkness, and R Pringle showed the results of interesting observations in patients with Raynaud's disease who had abnormal blood viscosities and flow cessation pressures The latter phenomenon was treated in a different manner by C G Caro, T H Foley and M F. Sudlow, who provided interesting data on the effect of altering the transmural pressure in normal human subjects The elastic behaviour of the wall of "living" blood vessels was considered by D J Patel and D L Fry J L Corbett and S H Milton showed that dye studies on the vascularity of experimental skin flaps in animals demonstrated considerable species variability, and B A Warren and M C Davey illustrated the ultrastructure of platelets and fibrin by means of electron photomicrographs

The symposium as a whole served to bring together workers in previously unrelated disciplines and it is hoped that the resulting introductions will foster closer relationships between these people Physicists, hydraulic engineers and rheologists would learn much of the problems of microcirculation if they were able to see living tissues and high speed photographs of blood cells in motion, and the more clinical research workers have much to learn of the methods and parameters needed before the solution of those problems is likely to yield to mathematical analysis

Pituitary Hormone Actions

from our Medical Biochemistry Correspondent

ALTHOUGH the pituitary gland is often described as the "conductor of the endocrine orchestra" because of the way in which pituitary hormones have stimulatory effects on many other endocrine glands, the way in which pituitary hormones act on their target tissues is not completely clear Three recent papers have shown that some pituitary hormones seem to have direct effects on some enzymes concerned with carbohydrate and fatty acid metabolism These effects might be responsible for their action on the metabolism of distant tissues

Bornstein and co-workers (*Biochim Biophys Acta*, **156**, 31, 1968) have isolated from anterior pituitary extracts two polypeptide fractions which they have named Ac-P and In-P Ac-P accelerates fatty acid synthesis from acetate in liver slices In-P inhibits fatty acid synthesis in liver slices and homogenates and the soluble fraction after separation of the homogenate particles In-P has also a strong inhibitory effect on glyceraldehyde 3-phosphate dehydrogenase and α-glycerophosphate dehydrogenase, but does not affect hexokinase, phosphofructokinase, aldolase, lactate dehydrogenase, glucose 6-phosphate dehydrogenase, alcohol dehydrogenase, malate dehydrogenase, isocitrate dehydrogenase, malic enzyme or aspartate aminotransferase

The same group has also shown that preparations of growth hormone will also inhibit glyceraldehyde 3-phosphate dehydrogenase, but only if the hormone has been treated with acid and then returned to neutral solution (*Biochim Biophys Acta*, **156**, 38, 1968) They were able to separate two polypeptide fractions from this acid-treated growth hormone The fraction called In-G inhibited glyceraldehyde 3-phosphate dehydrogenase and also decreased the incorporation of acetate into fatty acids in liver slices The other fraction, Ac-G, was able to prevent the inhibition caused by In-G without itself having any effect on the enzyme activity The two polypeptides appeared to be similar to, if not identical with, the two polypeptides extracted from the anterior pituitary Ac-G seems to reverse the dehydrogenase inhibition produced by In-P Because the action of these two peptides is in many ways antagonistic, growth hormone may have different effects on the metabolism of different tissues, depending on the tissue *p*H and possibly other factors

In the same journal, Butcher and Serif (*Biochim Biophys Acta*, **156**, 59, 1968) present evidence that another pituitary hormone, thyroid stimulating hormone (TSH), affects the carbohydrate-degrading enzyme phosphorylase Other workers have not been able to find phosphorylase in thyroid, but Butcher and Serif, using a new sensitive assay, have shown that thyroid does contain phosphorylase and that TSH changes the ratio of inactive phosphorylase *B* to the active phosphorylated form—phosphorylase *A* Within one minute after the addition of TSH, the proportion of phosphorylase *A* had increased substantially Since compounds related to cyclic adenosine 3′,5′-monophosphate produced the same effect, TSH may increase the cyclic adenosine 3′,5′-monophosphate and increase phosphorylase *A* indirectly. Phosphorylase is regarded as a key enzyme in the control of carbohydrate metabolism in other tissues, so that this effect of TSH may be important in thyroid stimulation Pituitary hormones may alter the metabolism of target tissues by these effects of key enzymes

Exchange of Ribosomal Sub-units

from our Cell Biology Correspondent

ARE the 30*S* and 50*S* sub-units of *Escherichia coli* ribosomes permanently associated *in vivo* in a 70*S* ribosome, or do they undergo exchange ? The elegant experiments which Kaempfer, Meselson and Raskas have just reported (*J Mol Biol*, **31**, 277, 1968) firmly establish that there is sub-unit exchange in *E coli* during protein synthesis Last year (see *Nature*, **216**, 853, 1967) Mangiarotti and Schlessinger reached the same conclusion from somewhat less compelling evidence

Kaempfer *et al* have analysed, on sucrose and caesium chloride density gradients, the density distribution of ribosomes extracted from *E coli* cells which had been uniformly labelled with heavy isotopes (deuterium and ^{15}N) and then transferred to a medium containing only light isotopes Following the classic Meselson and Stahl experiment, they argued that if sub-unit exchange occurs, then, on transfer to a light medium, heavy ribosomes should be progressively replaced by two species of ribosomes with hybrid densities One species of hybrid would have a heavy 50*S* sub-unit and a newly synthesized light 30*S* sub-unit and the other hybrid a light 50*S* and heavy 30*S* sub-unit This interpretation is only valid, of course, if the ribosomal sub-units labelled with heavy isotopes are stable and remain heavy when the cells are grown in a light medium

In fact, as predicted, both hybrid species are formed during growth in the light medium Furthermore, virtually all the ribosomes undergo at least one cycle of sub-unit exchange during a cell generation Kaempfer *et al* have found no evidence for ribosomes which were incapable of dissociation nor for the accumulation of sub-units that were unable to cycle through ribosomes Their experiments also show that ribosomal sub-units are stable, heavy 50*S* sub-units maintain their original density during growth in the light medium Less than 3 per cent of their protein is exchanged in 1 3 generations (about 1 h)

Ribosomal proteins are apparently themselves also stable during cell growth Schlief has recently reported (*Mol Gen Genetics*, **100**, 252, 1967) that the rate of degradation of ribosomal protein to free amino-acid cannot be greater than 0 7 per cent per hour

The simplest explanation of sub-unit exchange in growing cells is that it is a necessary step in protein synthesis The current interpretation is that a round of translation 30*S* and 50*S* sub-units from an intracellular pool join to form a ribosome and at the end of translation they dissociate and return to the pools (see *Nature*, **216**, 638, 1967, and **217**, 508, 1968) A search for evidence of sub-unit exchange in eucells is needed now

Carboxypeptidase

from our Molecular Biology Correspondent

THE successful determination of a protein structure at high resolution is still an event to be celebrated The structure of the proteolytic enzyme, carboxypeptidase *A*, at a resolution of 2 0 Å has been described by Lipscomb and his associates (Reeke *et al*, *Proc US Nat Acad Sci*, **58**, 2220, 1967) In the absence of extensive data on the sequence, many of the side chains cannot be uniquely identified, but the course of the backbone is unambiguous

The essential structural features include four α-helical regions making up some 30 per cent of the chain in all, and two sections of the distorted α-helix also seen in lysozyme are present The model bears out once more the ubiquity of the β-structure, for 20 per cent of the backbone has the form of a pleated sheet containing four pairs of parallel and three of antiparallel chains The active site, as elsewhere, is located in a cavity, and includes the zinc atom, which is present in the native enzyme and is required for activity Three side chains are thought to function as ligands for the zinc, but only one—a histidine residue—has been identified

The most interesting feature of this work concerns the introduction of a substrate, glycyltyrosine The electron density map of the complex at 2 8 Å reveals a number of aspects of the interaction, and in particular—by marked contrast, for example, with ribonuclease—shows that the entry of the substrate provokes appreciable local changes in disposition of side chains. There is no evidence of specific interactions between any groups in the enzyme and the C-terminal side chain of the substrate, which fits easily into the cavity. However, the terminal carboxylate group is brought into contact with an arginine side chain, which moves 2 Å in the process. It is tentatively suggested, moreover, that the oxygen atom of the substrate peptide bond may become a ligand for the zinc atom. It was previously observed by Vallee and co-workers that certain tyrosine residues seem to be involved in enzymatic activity, and indeed it is found that one tyrosine moves a distance of no less than 14 Å when the substrate is introduced so as to bring up the phenolic hydroxyl group close to the substrate peptide bond. The motion occurs in a non-helical part of the chain, and evidently involves a considerable disturbance of the backbone conformation as well as rotation about side chain carbon–carbon bonds. A carboxylate group also seems to form part of the active site.

The details so far available are consistent with chemical data: whether a more precise delineation of the interaction between the active centre and the substrate will immediately suggest a catalytic mechanism remains to be seen. There are grounds for optimism, despite the remarkable failure of known protein structures so far to reveal the mechanism of their function unequivocably.

Observation of a Rapidly Pulsating Radio Source

by

A. HEWISH
S. J. BELL
J. D. H. PILKINGTON
P. F. SCOTT
R. A. COLLINS

Mullard Radio Astronomy Observatory,
Cavendish Laboratory,
University of Cambridge

Unusual signals from pulsating radio sources have been recorded at the Mullard Radio Astronomy Observatory. The radiation seems to come from local objects within the galaxy, and may be associated with oscillations of white dwarf or neutron stars.

IN July 1967, a large radio telescope operating at a frequency of 81.5 MHz was brought into use at the Mullard Radio Astronomy Observatory. This instrument was designed to investigate the angular structure of compact radio sources by observing the scintillation caused by the irregular structure of the interplanetary medium[1]. The initial survey includes the whole sky in the declination range $-08° < \delta < 44°$ and this area is scanned once a week. A large fraction of the sky is thus under regular surveillance. Soon after the instrument was brought into operation it was noticed that signals which appeared at first to be weak sporadic interference were repeatedly observed at a fixed declination and right ascension; this result showed that the source could not be terrestrial in origin.

Systematic investigations were started in November and high speed records showed that the signals, when present, consisted of a series of pulses each lasting ~ 0.3 s and with a repetition period of about 1.337 s which was soon found to be maintained with extreme accuracy. Further observations have shown that the true period is constant to better than 1 part in 10^7 although there is a systematic variation which can be ascribed to the orbital motion of the Earth. The impulsive nature of the recorded signals is caused by the periodic passage of a signal of descending frequency through the 1 MHz pass band of the receiver.

The remarkable nature of these signals at first suggested an origin in terms of man-made transmissions which might arise from deep space probes, planetary radar or the reflexion of terrestrial signals from the Moon. None of these interpretations can, however, be accepted because the absence of any parallax shows that the source lies far outside the solar system. A preliminary search for further pulsating sources has already revealed the presence of three others having remarkably similar properties which suggests that this type of source may be relatively common at a low flux density. A tentative explanation of these unusual sources in terms of the stable oscillations of white dwarf or neutron stars is proposed.

Position and Flux Density

The aerial consists of a rectangular array containing 2,048 full-wave dipoles arranged in sixteen rows of 128 elements. Each row is 470 m long in an E–W direction and the N–S extent of the array is 45 m. Phase-scanning is employed to direct the reception pattern in declination and four receivers are used so that four different declinations may be observed simultaneously. Phase-switching receivers are employed and the two halves of the aerial are combined as an E–W interferometer. Each row of dipole elements is backed by a tilted reflecting screen so that maximum sensitivity is obtained at a declination of approximately $+30°$, the overall sensitivity being reduced by more than one-half when the beam is scanned to declinations above $+90°$ and below $-5°$. The beamwidth of the array to half intensity is about $\pm\frac{1}{2}°$ in right ascension and $\pm 3°$ in declination; the phasing arrangement is designed to produce beams at roughly 3° intervals in declination. The receivers have a bandwidth of 1 MHz centred at a frequency of 81.5 MHz and routine recordings are made with a time constant of 0.1 s; the r.m.s. noise fluctuations correspond to a flux density of 0.5×10^{-26} W m^{-2} Hz^{-1}. For detailed studies of the pulsating source a time constant of 0.05 s was usually employed and the signals were displayed on a multi-channel 'Rapidgrap' pen recorder with a time constant of 0.03 s. Accur timing of the pulses was achieved by recording ser pips derived from the *MSF* Rugby time transmissic

A record obtained when the pulsating source w

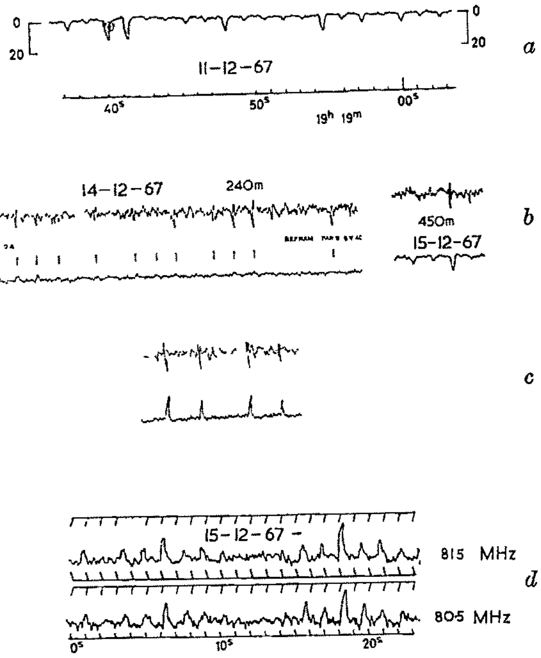


Fig 1 *a*, A record of the pulsating radio source in strong signal conditions (receiver time constant 0 1 s) Full scale deflexion corresponds to 20×10^{-26} W m^{-2} Hz^{-1} *b*, Upper trace records obtained with additional paths (240 m and 450 m) in one side of the interferometer Lower trace normal interferometer records (The pulses are small for $l=240$ m because they occurred near a null in the interference pattern, this modifies the phase but not the amplitude of the oscillatory response on the upper trace) *c*, Simulated pulses obtained using a signal generator *d*, Simultaneous reception of pulses using identical receivers tuned to different frequencies Pulses at the lower frequency are delayed by about 0 2 s

usually strong is shown in Fig. 1*a* This clearly displays the regular periodicity and also the characteristic irregular variation of pulse amplitude. On this occasion the largest pulses approached a peak flux density (averaged over the 1 MHz pass band) of 20×10^{-26} W m^{-2} Hz^{-1}, although the mean flux density integrated over one minute only amounted to approximately $1\ 0 \times 10^{-26}$ W m^{-2} Hz^{-1} On a more typical occasion the integrated flux density would be several times smaller than this value It is therefore not surprising that the source has not been detected in the past, for the integrated flux density falls well below the limit of previous surveys at metre wavelengths

The position of the source in right ascension is readily obtained from an accurate measurement of the "crossover" points of the interference pattern on those occasions when the pulses were strong throughout an interval embracing such a point The collimation error of the instrument was determined from a similar measurement on the neighbouring source 3*C* 409 which transits about 52 min later On the routine recordings which first revealed the source the reading accuracy was only ±10 s and the earliest record suitable for position measurement was obtained on August 13, 1967. This and all subsequent measurements agree within the error limits. The position in declination is not so well determined and relies on the relative amplitudes of the signals obtained when the reception pattern is centred on declinations of 20°, 23° and 26°. Combining the measurements yields a position

$$\alpha_{1950} = 19\text{h}\ 19\text{m}\ 38\text{s} \pm 3\text{s}$$

$$\delta_{1950} = 22^\circ\ 00' \pm 30'$$

As discussed here, the measurement of the Doppler shift in the observed frequency of the pulses due to the Earth's orbital motion provides an alternative estimate of the declination Observations throughout one year should yield an accuracy of ±1′ The value currently attained from observations during December–January is $\delta = 21^\circ\ 58' \pm 30'$, a figure consistent with the previous measurement

Time Variations

It was mentioned earlier that the signals vary considerably in strength from day to day and, typically, they are only present for about 1 min, which may occur quite randomly within the 4 min interval permitted by the reception pattern In addition, as shown in Fig 1*a*, the pulse amplitude may vary considerably on a time-scale of seconds. The pulse to pulse variations may possibly be explained in terms of interplanetary scintillation[1], but this cannot account for the minute to minute variation of mean pulse amplitude Continuous observations over periods of 30 min have been made by tracking the source with an E -W phased array in a 470 m × 20 m reflector normally used for a lunar occultation programme The peak pulse amplitude averaged over ten successive pulses for a period of 30 min is shown in Fig 2*a* This plot suggests the possibility of periodicities of a few minutes duration, but a correlation analysis yields no significant result If the signals were linearly polarized, Faraday rotation in the ionosphere might cause the random variations, but the form of the curve does not seem compatible with this mechanism The day to day variations since the source was first detected are shown in Fig. 2*b*. In this analysis the daily value plotted is the peak flux density of the greatest pulse Again the variation from day to day is irregular and no systematic changes are clearly evident, although there is a suggestion that the source was significantly weaker during October to November. It therefore appears that, despite the regular occurrence of the pulses, the magnitude of the power emitted exhibits variations over long and short periods

Instantaneous Bandwidth and Frequency Drift

Two different experiments have shown that the pulses are caused by a narrow-band signal of descending frequency sweeping through the 1 MHz band of the receiver. In the first, two identical receivers were used, tuned to frequencies of 80 5 MHz and 81 5 MHz Fig 1*d*, which illustrates a record made with this system, shows that the lower frequency pulses are delayed by about 0 2 s This corresponds to a frequency drift of ~ -5 MHz s^{-1}. In the second method a time delay was introduced into the signals reaching the receiver from one-half of the aerial by incorporating an extra cable of known length l This cable introduces a phase shift proportional to frequency so that, for a signal the coherence length of which exceeds l, the output of the receiver will oscillate with period

$$t_0 = \frac{c}{l}\left(\frac{d\nu}{dt}\right)^{-1}$$

where $d\nu/dt$ is the rate of change of signal frequency Records obtained with $l=240$ m and 450 m are shown in Fig 1*b* together with a simultaneous record of the pulses derived from a separate phase-switching receiver operating with equal cables in the usual fashion Also shown, in Fig. 1*c*, is a simulated record obtained with exactly the same arrangement but using a signal generator, instead of the source, to provide the swept frequency For observation with $l > 450$ m the periodic oscillations were slowed down to a low frequency by an additional phase shifting device in order to prevent severe attenuation of the output signal by the time constant of the receiver The rate of change of signal frequency has been deduced from the additional phase shift required and is $d\nu/dt = -4\ 9 \pm 0\ 5$ MHz s^{-1}. The direction of the frequency drift can be obtained from the phase of the oscillation on the record and is found to be from high to low frequency in agreement with the first result

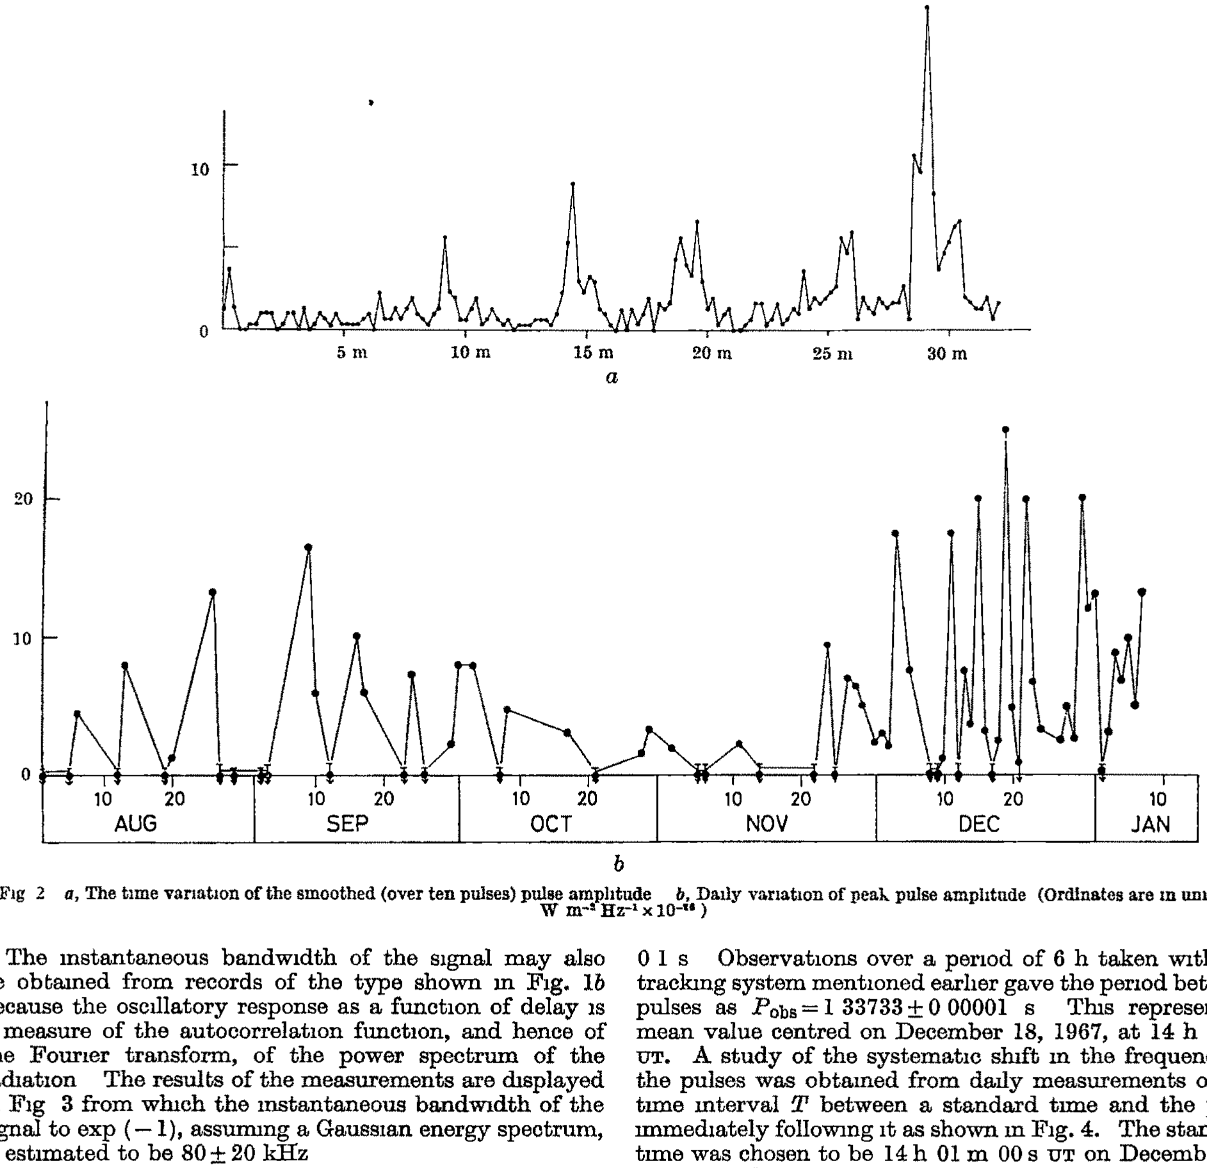

Fig 2 *a*, The time variation of the smoothed (over ten pulses) pulse amplitude *b*, Daily variation of peak pulse amplitude (Ordinates are in units of W m^{-2} Hz^{-1} $\times 10^{-26}$)

The instantaneous bandwidth of the signal may also be obtained from records of the type shown in Fig. 1*b* because the oscillatory response as a function of delay is a measure of the autocorrelation function, and hence of the Fourier transform, of the power spectrum of the radiation The results of the measurements are displayed in Fig 3 from which the instantaneous bandwidth of the signal to exp (-1), assuming a Gaussian energy spectrum, is estimated to be 80 ± 20 kHz

Pulse Recurrence Frequency and Doppler Shift

By displaying the pulses and time pips from *MSF* Rugby on the same record the leading edge of a pulse of reasonable size may be timed to an accuracy of about 0 1 s Observations over a period of 6 h taken with the tracking system mentioned earlier gave the period between pulses as $P_{\mathrm{obs}} = 1\ 33733 \pm 0\ 00001$ s This represents a mean value centred on December 18, 1967, at 14 h 18 m UT. A study of the systematic shift in the frequency of the pulses was obtained from daily measurements of the time interval T between a standard time and the pulse immediately following it as shown in Fig. 4. The standard time was chosen to be 14 h 01 m 00 s UT on December 11 (corresponding to the centre of the reception pattern) and subsequent standard times were at intervals of 23 h 56 m 04 s (approximately one sidereal day) A plot of the variation of T from day to day is shown in Fig 4 A constant pulse recurrence frequency would show a linear increase or decrease in T if care was taken to add or subtract one period where necessary The observations, however, show a marked curvature in the sense of a steadily increasing frequency. If we assume a Doppler shift due to the Earth alone, then the number of pulses received per day is given by

$$N = N_0 \left(1 + \frac{v}{c} \cos \varphi \sin \frac{2\pi n}{366\ 25}\right)$$

where N_0 is the number of pulses emitted per day at the source, v the orbital velocity of the Earth, φ the ecliptic latitude of the source and n an arbitrary day number obtained by putting $n = 0$ on January 17, 1968, when the Earth has zero velocity along the line of sight to the source This relation is approximate since it assumes a circular orbit for the Earth and the origin $n = 0$ is not exact, but it serves to show that the increase of N observed can be explained by the Earth's motion alone within the accuracy currently attainable. For this purpose it is convenient to estimate the values of n for which $\delta T/\delta n = 0$, corresponding to an exactly integral value of N. These occur at $n_1 = 15\ 8 \pm 0{\cdot}1$ and $n_2 = 28\ 7 \pm 0\ 1$, and since N

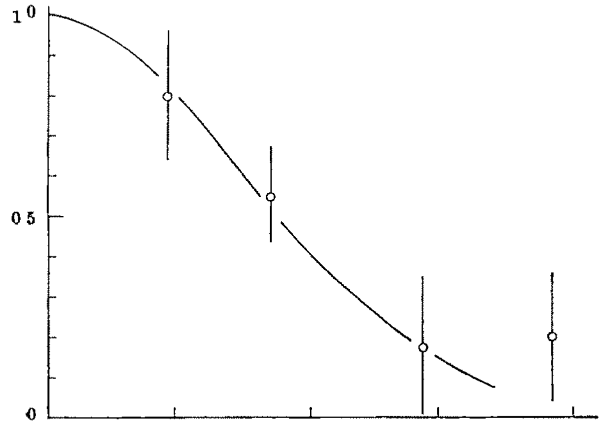

Fig 3 The response as a function of added path in one side of the interferometer

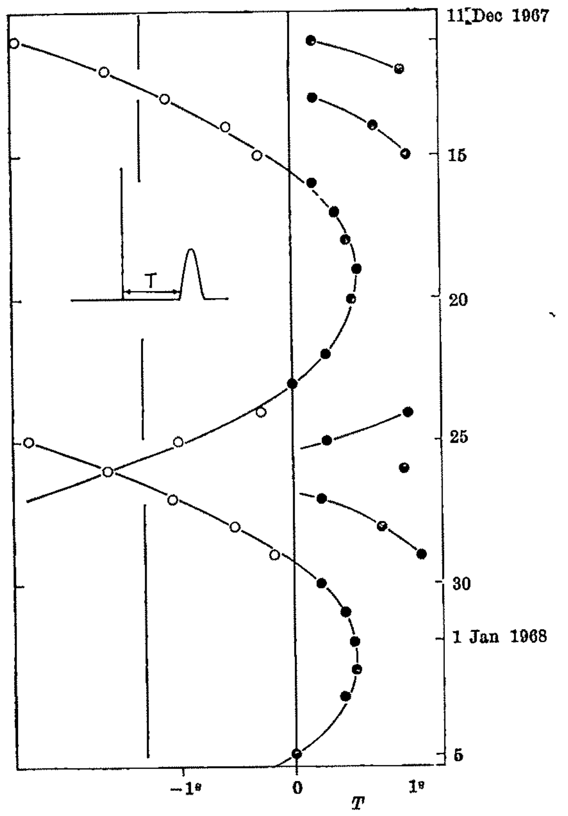

Fig. 4. The day to day variation of pulse arrival time

is increased by exactly one pulse between these dates we have

$$1=\frac{N_0 v}{c}\cos\varphi\left[\sin\frac{2\pi n_2}{366\cdot25}-\sin\frac{2\pi n_1}{366\cdot25}\right]$$

This yields $\varphi=43°\ 36'\pm30'$ which corresponds to a declination of $21°\ 58'\pm30'$, a value consistent with the declination obtained directly. The true periodicity of the source, making allowance for the Doppler shift and using the integral condition to refine the calculation, is then

$$P_0=1\cdot3372795\pm0\cdot0000020\text{ s}$$

By continuing observations of the time of occurrence of the pulses for a year it should be possible to establish the constancy of N_0 to about 1 part in 3×10^8. If N_0 is indeed constant, then the declination of the source may be estimated to an accuracy of $\pm1'$, this result will not be affected by ionospheric refraction.

It is also interesting to note the possibility of detecting a variable Doppler shift caused by the motion of the source itself. Such an effect might arise if the source formed one component of a binary system, or if the signals were associated with a planet in orbit about some parent star. For the present, the systematic increase of N is regular to about 1 part in 2×10^7 so that there is no evidence for an additional orbital motion comparable with that of the Earth.

The Nature of the Radio Source

The lack of any parallax greater than about 2′ places the source at a distance exceeding 10^3 A.U. The energy emitted by the source during a single pulse, integrated over 1 MHz at 81·5 MHz, therefore reaches a value which must exceed 10^{17} erg if the source radiates isotropically. It is also possible to derive an upper limit to the physical dimension of the source. The small instantaneous bandwidth of the signal (80 kHz) and the rate of sweep ($-4\cdot9$ MHz s^{-1}) show that the duration of the emission at any given frequency does not exceed 0·016 s. The source size therefore cannot exceed $4\cdot8\times10^3$ km.

An upper limit to the distance of the source may be derived from the observed rate of frequency sweep since impulsive radiation, whatever its origin, will be dispersed during its passage through the ionized hydrogen in interstellar space. For a uniform plasma the frequency drift caused by dispersion is given by

$$\frac{d\nu}{dt}=-\frac{c}{L}\frac{\nu^3}{\nu_p^2}$$

where L is the path and ν_p the plasma frequency. Assuming a mean density of 0·2 electron cm^{-3} the observed frequency drift ($-4\cdot9$ MHz s^{-1}) corresponds to $L\sim65$ parsec. Some frequency dispersion may, of course, arise in the source itself, in this case the dispersion in the interstellar medium must be smaller so that the value of L is an upper limit. While the interstellar electron density in the vicinity of the Sun is not well known, this result is important in showing that the pulsating radio sources so far detected must be local objects on a galactic distance scale.

The positional accuracy so far obtained does not permit any serious attempt at optical identification. The search area, which lies close to the galactic plane, includes two twelfth magnitude stars and a large number of weaker objects. In the absence of further data, only the most tentative suggestion to account for these remarkable sources can be made.

The most significant feature to be accounted for is the extreme regularity of the pulses. This suggests an origin in terms of the pulsation of an entire star, rather than some more localized disturbance in a stellar atmosphere. In this connexion it is interesting to note that it has already been suggested[2,3] that the radial pulsation of neutron stars may play an important part in the history of supernovae and supernova remnants.

A discussion of the normal modes of radial pulsation of compact stars has recently been given by Meltzer and Thorne[4], who calculated the periods for stars with central densities in the range 10^5 to 10^{19} g cm^{-3}. Fig. 4 of their paper indicates two possibilities which might account for the observed periods of the order 1 s. At a density of 10^7 g cm^{-3}, corresponding to a white dwarf star, the fundamental mode reaches a minimum period of about 8 s, at a slightly higher density the period increases again as the system tends towards gravitational collapse to a neutron star. While the fundamental period is not small enough to account for the observations the higher order modes have periods of the correct order of magnitude. If this model is adopted it is difficult to understand why the fundamental period is not dominant, such a period would have readily been detected in the present observations and its absence cannot be ascribed to observational effects. The alternative possibility occurs at a density of 10^{13} g cm^{-3}, corresponding to a neutron star, at this density the fundamental has a period of about 1 s, while for densities in excess of 10^{13} g cm^{-3} the period rapidly decreases to about 10^{-3} s.

If the radiation is to be associated with the radial pulsation of a white dwarf or neutron star there seem to be several mechanisms which could account for the radio emission. It has been suggested that radial pulsation would generate hydromagnetic shock fronts at the stellar surface which might be accompanied by bursts of X-rays and energetic electrons[2,3]. The radiation might then be likened to radio bursts from a solar flare occurring over the entire star during each cycle of the oscillation. Such a model would be in fair agreement with the upper limit of $\sim5\times10^3$ km for the dimension of the source, which compares with the mean value of 9×10^3 km quoted for white dwarf stars by Greenstein[5]. The energy requirement for this model may be roughly estimated by noting that the total energy emitted in a 1 MHz band by a type III solar burst would produce a radio flux of the right order if the source were at a distance of $\sim10^3$ A.U. If it is assumed that the radio energy may be related to the total flare energy ($\sim 10^{32}$ erg)[6] in the same manner as for a solar flare and supposing that each pulse corresponds to one flare, the required energy would be $\sim 10^{39}$ erg yr^{-1}, at a distance of 65 pc the corresponding value would be $\sim 10^{47}$ erg yr^{-1} It has been estimated that a neutron star may contain $\sim 10^{51}$ erg in vibrational modes so the energy requirement does not appear unreasonable, although other damping mechanisms are likely to be important when considering the lifetime of the source[4]

The swept frequency characteristic of the radiation is reminiscent of type II and type III solar bursts, but it seems unlikely that it is caused in the same way For a white dwarf or neutron star the scale height of any atmosphere is small and a travelling disturbance would be expected to produce a much faster frequency drift than is actually observed As has been mentioned, a more likely possibility is that the impulsive radiation suffers dispersion during its passage through the interstellar medium

More observational evidence is clearly needed in order to gain a better understanding of this strange new class of radio source If the suggested origin of the radiation is confirmed further study may be expected to throw valuable light on the behaviour of compact stars and also on the properties of matter at high density

We thank Professor Sir Martin Ryle, Dr J E Baldwin, Dr P A G. Scheuer and Dr J R Shakeshaft for helpful discussions and the Science Research Council who financed this work One of us (S J B) thanks the Ministry of Education of Northern Ireland and another (R A C) the SRC for a maintenance award, J D H P thanks ICI for a research fellowship

Action Potentials induced in Biomolecular Lipid Membranes

by
PAUL MUELLER
DONALD O. RUDIN
Department of Basic Research,
Eastern Pennsylvania Psychiatric Institute,
Philadelphia, Pennsylvania

Alamethicin, a cyclopeptide, can induce action potentials in biomolecular lipid membranes.

ALAMETHICIN, a cyclopeptide antibiotic from *Trichoderma viride* containing the amino-acids $(GluN)_2$, $(Glu)_1$, $(Pro)_2$, $(Gly)_1$, $(Ala)_2$, (Methyl $Ala)_8$, $(Val)_2$ and $(Leu)_1$ (ref 1), develops a cationic conductance in experimental bilayers which can be controlled by a factor of 10^4 either chemically or by changing the membrane potential using applied voltages or ionic gradients When it is brought together with an ionic gradient and a few μg/ml of protamine, polylysine or spermine in the aqueous phase, the membranes develop characteristics of negative slope resistance (Fig 1), delayed rectification (Fig 2), bistable changes of EMF (Fig 3*A*) and single or rhythmic action potentials (Fig 3*B* and *C*) These changes resemble those occurring in excitable algae or those produced in bilayers by an unidentified proteinaceous material obtained from *Enterobacter cloacae* called excitability inducing material (EIM)[2,3]. As shown in Fig 4, alamethicin structurally resembles other macrocyclic compounds like the depsipeptides and macrolids which develop extreme K^+/Na^+ selective conductances of an ohmic nature in experimental bilayers[4] Alamethicin, however, is a pure peptide containing functional side groups

The electrokinetic and chemical data suggest that six or more alamethicin molecules form either carriers or tubular channels through which ions flow across the membrane and that assembly and dissembly of these aggregates by the voltage or chemical factors regulate the conductance The kinetic and chemical characteristics of alamethicin apparently fulfil the criteria of an allosteric protein specifically designed to form complexes of ionic co-ordination within lipid membranes We discuss the possibility that related compounds could generate active ion transport and act as high energy intermediates in oxidative phosphorylation

Bilayer membranes separating two aqueous phases were made by published methods[2,3,5] Alamethicin acts on membranes made from mixed brain lipids and tocopherol, lecithin and decane, sphingomyelin and tocopherol[2,3] or oxidized cholesterol and octane[6], although the sensitivity to alamethicin and to protamine varies from one lipid type to another Best results were obtained with membranes made from oxidized cholesterol (1 per cent), dodecyl acid phosphate (0 25 per cent), cholesterol (0 42 per cent in octane dodecane, 1 3[6]) and with membranes made from purified lecithin (10 per cent in decane–squalene, 2 1) In the presence of adsorbates the life of the membrane lasts from a few minutes to several hours according to the type of lipid Alamethicin can be introduced either by dissolving it in the bulk lipid solution or by adding it to the aqueous phase after bilayer formation

Fig 1 presents three steady state current–voltage, I(V), curves in the presence of 10^{-7} g/ml of alamethicin on one side of the membrane With 0 1 M sodium chloride on both sides, the membrane shows strong and more or less symmetrical rectification (Fig 1*A*) The conductance decreases 10^4 times between zero and 100 mV and attains a maximum change of *e*-fold/5 mV An ionic gradient generates a cationic resting potential of 10–30 mV/decade without intracationic selectivity. This acts like an applied potential to drive the system into its high conductance state although it does not deliver a net current As shown in Fig 1*B*, the resting potential shifts the I(V) curve along the voltage axis, raises the resting conductance and, for analytical reasons given elsewhere[3], transforms the rectification characteristic in one quadrant into a characteristic of negative slope resistance If protamine is added to either aqueous phase under zero ion gradient there is a similar effect as shown in Fig 1*C* The resting conductance is increased and a negative resistance arises in the absence of a resting potential This is the first of three distinct effects produced by protamine, histone or spermine acting as secondary adsorbates Because this particular effect resembles that of a resting potential it may result from a change in the phase boundary potential accompanying adsorption of basic proteins or polyamines

The voltage–time phenomena generated by constant current pulses in the three sets of conditions just described are given in Fig 2 If the system rests in its low conductance state corresponding to Fig 1*A*, applied voltages raise the conductance This usually occurs slowly with respect to the time constant of the membrane so that the positive coupling between the conductance and the potential produces a delayed voltage restoring effect shown in Fig 2*A* If the system rests in its high conductance state in the conditions of Fig 1*B* or *C*, then applied voltages of that sign which drive it back into the low conductance state develop the regenerative transition shown in Fig 2*B* because the two variables are now negatively coupled But voltages of opposite sign which raise the conductance again develop the delayed rectification process It has already been shown that EIM can generate these same phenomena and change its resting conductance state under the influence of either a resting potential or chemical agents[2,3] It should be noted, however, that, in contrast to alamethicin, EIM remains intrinsically in the high conductance state

The second effect of protamine, histone or spermine is to introduce an alternative resting potential level of

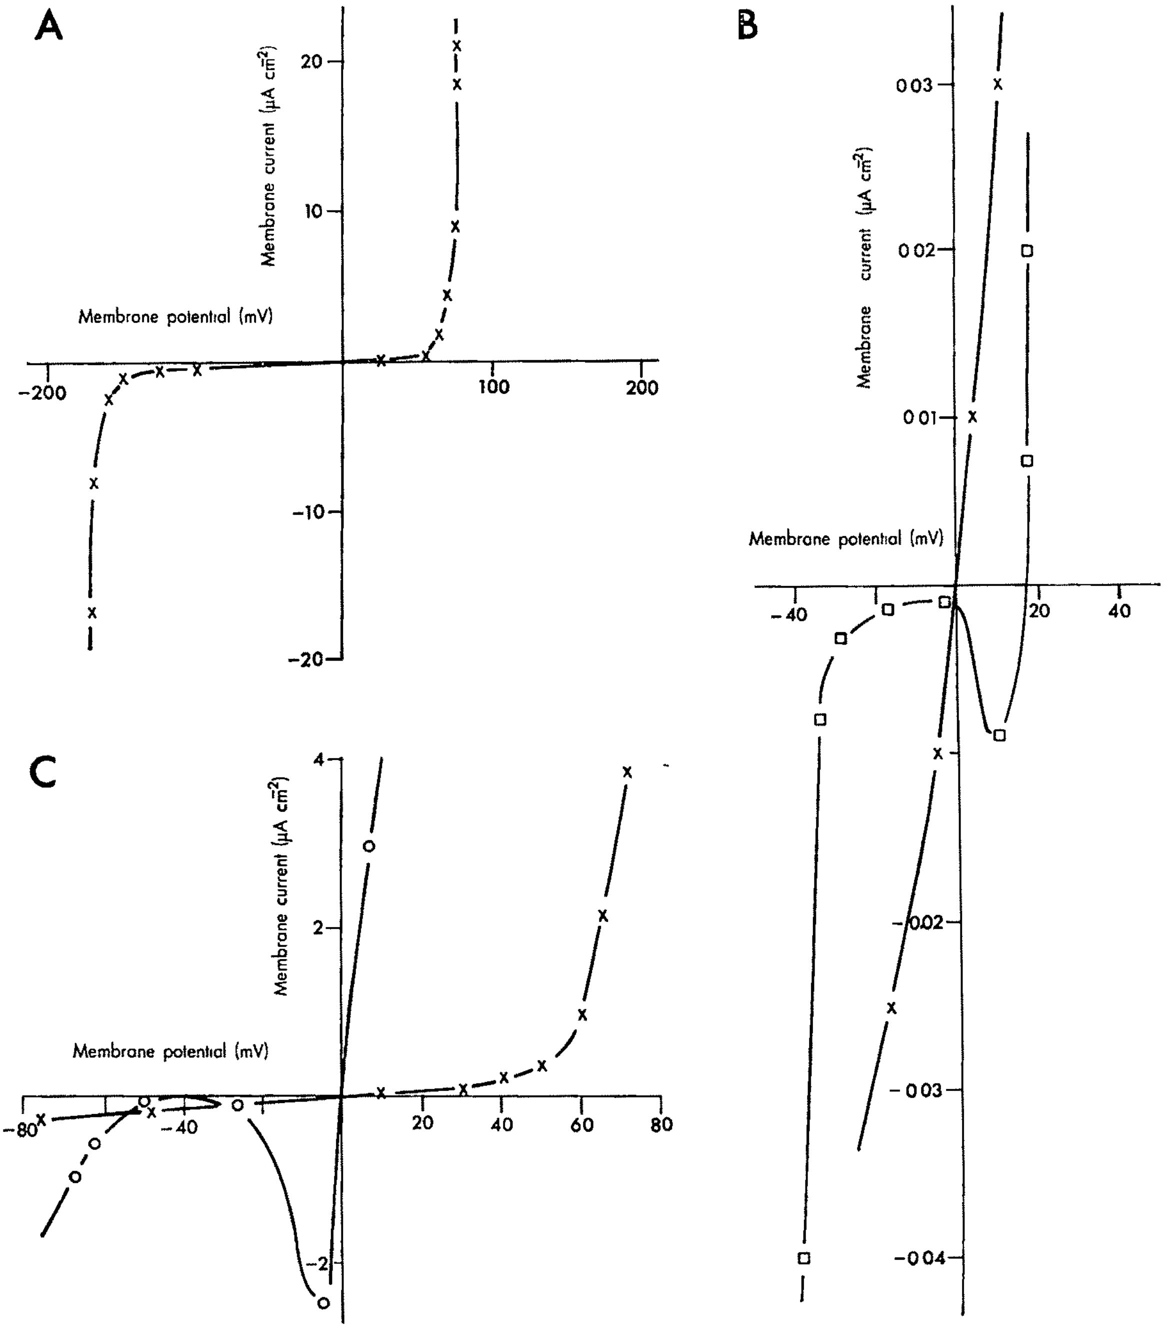

Fig 1 Current–voltage curves from different bimolecular lipid membranes in the presence of 10^{-7} g cm^{-3} alamethicin in the inside aqueous compartment and 5 mM/l histidine Cl, *p*H 7 0, in both sides in all cases Outward current is plotted as positive and the potential is that of the inside compartment minus that of the outside *A*, 0 1 M sodium chloride on both sides Membrane solution 2 5 per cent purified sphingomyelin in tocopherol chloroform methanol, 5 3 2 The asymmetry of the rectification characteristic is because alamethicin was added to one side only *B*, (squares) Membrane solution same as upper left but 0 05 M sodium chloride outside only There is a resting potential at the point of zero current caused bv the ionic concentration gradient The ion gradient also develops a negative resistance The upper left curve (crosses) is reproduced for comparison *C*, (circles) 0 1 M sodium chloride both sides and 10^{-4} g cm^{-3} protamine sulphate inside Membrane solution 4 per cent oxidized cholesterol in decane Protamine converts the rectification into a negative resistance characteristic The curve of Fig *A* (crosses) is reproduced on these expanded ordinates for comparison

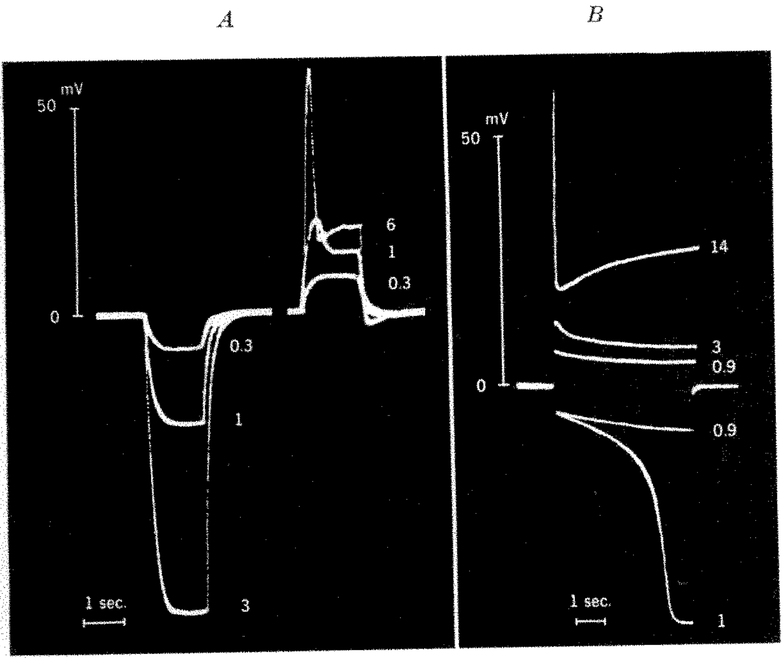

Fig. 2. Recorded membrane potentials in response to applied constant rectangular currents in the presence of 10^{-7} g cm^{-3} alamethicin in the inside compartment and 5 mM/l. histidine Cl, *p*H 7·0, in both sides in all cases. Upward deflexions denote inside positive. Numbers indicate the current density in μA cm^{-2}. *A*, 0·1 M sodium chloride in both compartments, 10^{-5} g cm^{-3} protamine inside. Membrane solution: 5 per cent total white matter lipids plus 3 per cent cholesterol in 3 : 4 : 2, tocopherol : chloroform : methanol. If there had been no protamine, the rectification would have been more nearly instantaneous and the potentials would show less initial upward transient. *B*, Same as above but using 10^{-4} g cm^{-3} protamine and a membrane solution of 4 per cent oxidized cholesterol in decane. Increasing the protamine concentration develops the regenerative non-linear response to inward currents which correspond to the negative resistance characteristic in the I(V) curve of Fig. 1*C* (circles).

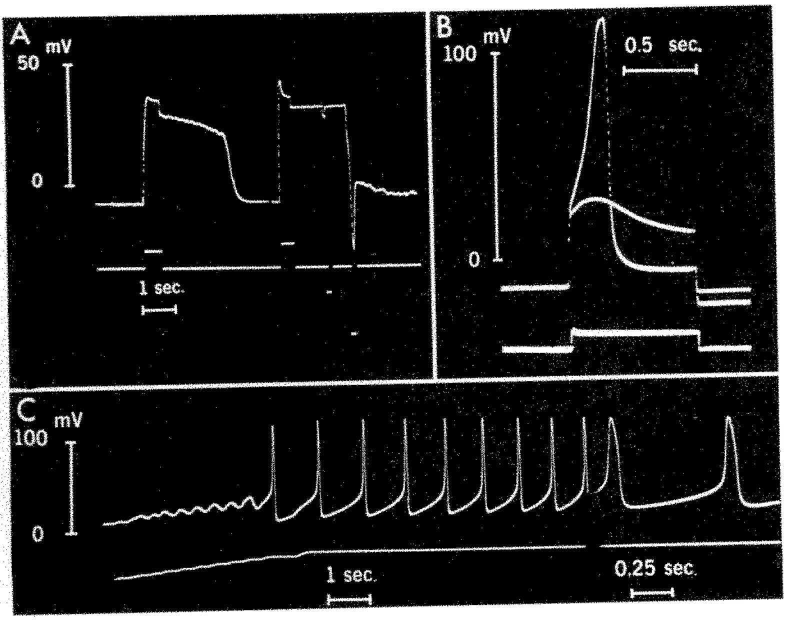

Fig. 3. Conditions as in Fig. 2*B* but 40 mM/l. potassium chloride inside and none outside. The lower traces show the applied currents. *A*, Bistability caused by a slight excess of protamine. The system was monostable initially as seen in the response to the first pulse, but then it became intrinsically bistable. Because there is no steady applied polarization the response results from an EMF change. The resistance is lower in the more anion permeable state which is the uppermost level. *B*, Subthreshold response and monostable action potential during applied depolarizing pulses. *C*, Rhythmic firing begins as the depolarizing current is increased to a critical level. Note expanded time scale on the right. These action potentials and those in *B* are largely resistive in type, the resistance increasing during the spike. They occur at depolarization levels greater than those initiating the EMF changes in the upper left figure and always require sustained applied voltages for their development. Lecithin–decane–squalene membranes, in the same conditions, develop self-regenerative single or rhythmic action potentials which can be initiated by brief currents or appear in the absence of any applied currents. Their amplitude is usually 30 to 60 mV but their wave form and frequency are identical to those in records *B* and *C*.

anionic sign. If, in the presence of an ionic gradient, the concentration of protamine is carefully titrated against alamethicin, the membrane potential becomes bistable and switches reversibly through zero from the original cationic level to the new level under the stimulus of brief applied pulses (Fig. 3*A*). The anionic level is more effectively developed by arginine-rich than lysine-rich basic proteins and by membranes containing sphingomyelin rather than lecithin. Although any combination will work with alamethicin, only the first member of each pair is effective with EIM[3].

In membranes composed of oxidized cholesterol and dodecyl acid phosphate "resistive action potentials" occur as shown in Fig. 3*B*. They resemble those occurring in frog skin[7] and in bilayers exposed to EIM in certain conditions[3]. They can enter the rhythmic state under maintained polarization (Fig. 3*C*) when the chemical parameters are properly adjusted. They are not self-regenerative and do not make use of the EMF change just described but seem to involve a secondary increase of the membrane resistance induced by protamine. This new gating characteristic constitutes the third effect of basic proteins.

In membranes composed of selected types of commercial purified lecithin containing squalene and decane, it is possible to adjust the ionic gradient and the ratio of alamethicin to protamine, so that the bistable flip-flop kinetics shown in Fig. 3*A* become monostable and generate either spontaneous rhythmic firing in the absence of applied voltages, or single action potential responses following short shock stimulation. These self-regenerative action potentials have all the kinetic properties of cellular action potentials and are similar to those already described in sphingomyelin membranes containing EIM and protamine[2,3]. Their time course and frequency are like those shown in Fig. 3*B* and *C* except that their amplitude is about 30–60 mV.

Fig. 5 shows that the maximum change of the steady state conductance varies exponentially with the sixth power of the potential (*e*-fold/5 mV) for a wide range of alamethicin concentrations. This is the same value reported for the potassium permeability system in nerve[8]. In addition, Fig. 6*A* shows that the steady state conductance also varies as the sixth power of both the alamethicin concentration and the ion concentration. Furthermore, this relation has been found to be independent of the voltage. These findings indicate that the molecularity of the reaction underlying the development of the conductance is hexamolecular with respect to both alamethicin and ions. It is also hexamolecular both in the resting state and when it is voltage induced.

The apparent kinetic order of the reaction is also six. As in nerve[8], the membrane current and conductance undergo a sigmoid rise with time following an instantaneous displacement of the potential by voltage clamp methods. The time constant of the response is voltage dependent and larger for the conductance increase than the decrease. The maximal rate of change de-

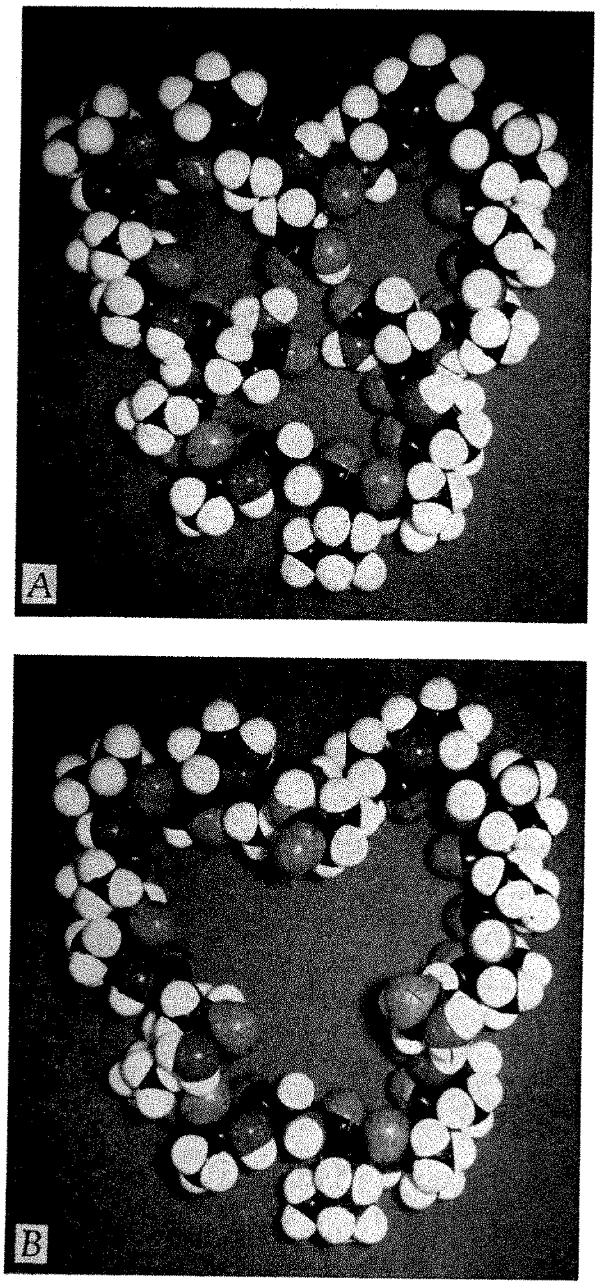

Fig. 4. Two hypothetical molecular configurations of alamethicin: *A*, By rotating the carboxyl and amide groups out of the plane of the ring, an open ring configuration is attained which might conduct by acting either as a carrier or as part of a channel. In addition to the peptide bonds, the three functional side groups could contribute to the formation of a hexamer of tubular or other shape via intermolecular hydrogen or ionic bonding. *B*, Intramolecular chelate. The carboxyl group of the glutamic acid side chain is arranged to form internal hydrogen bonds or possibly a metal ion chelate with the two glutamine residues. This may be the monomeric non-conducting form. The electrokinetic data suggest that the field regulates the conductance by moving monomeric co-ordination complexes of counterion and alamethicin which are positively charged into the hydrocarbon region of the bilayer where they form a hexameric channel unit. The ion with a partial hydration shell is thought to be sequestered within the ring.

pends strongly on the lipid type, ionic strength, the temperature (Q_{10} 3–4), and the presence of protamine. When these parameters are held constant, then the maximum rate is found to increase with the sixth power of the alamethicin concentration as shown in Fig. 6*B*. Hence the reaction is kinetically of the sixth order with respect to this parameter.

Voltage clamp studies have also shown that, if an applied voltage is instantaneously reversed in sign, the reversed membrane current undergoes a marked decline before building up again to its starting level showing that the conducting system exists in some well defined polarized state across the membrane.

We may begin the evaluation of these findings with a consideration of the origin of the ion selective conductances. It has been proposed[4] that macrocyclic compounds develop a cationic conductance by providing a dominating proton acceptor function in the form of carbonyl oxygen atoms. These atoms project toward the centre of the ring to form an adjustable co-ordination complex with either the naked or hydrated cation by means of multiple hydrogen bonds or dipole interactions. This orientation simultaneously sequesters the ion while placing the hydrocarbon side chains along the ring exterior to permit membrane solubilization of the entire charges complex by van der Waals interaction with the lipid hydrocarbon chains. Similar co-ordination complexes might also be formed by non-covalent ring closures as in the case of the gramicidins[4,9] or perhaps even by an open helix.

In this view, the poor intracationic selectivity of alamethicin would result from a larger ring diameter (13 Å inner diameter) compared with valinomycin (7 Å), for example. Basic proteins and spermine may invert the sign of this conductance, and therefore the sign of the resting potential in an ionic gradient, by increasing the ratio of proton donors and positive charges to proton acceptors and negative charges in the conducting system. Because protamine and sphingomyelin are essentially chemical analogues of histones and lecithin containing two extra proton donor groups in each case, protamine would be expected to be more effective in converting the ionic selectivity as is observed experimentally.

When the titration of protamine against alamethicin is not carried to completion, two distinct conducting populations with different selectivities could arise, provided the effect involves specific chemical complex formation and not a diffuse effect on the Donnan potential.

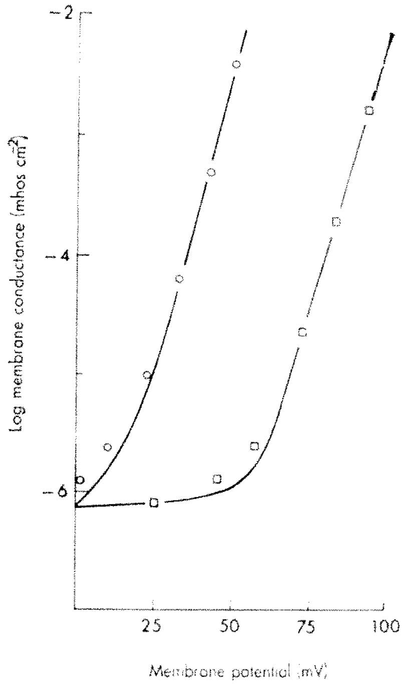

Fig. 5. The relation between membrane conductance and applied potential at two different concentrations of alamethicin in the aqueous phase (circles 5×10^{-8} g/ml., squares 10^{-6} g/ml.) membrane lipid composition as in Fig. 1*A*. Ionic concentrations in both aqueous compartments, 0·1 M sodium chloride. The points are experimental; the curves were calculated from equations (3), (4) and (6) using the following values for the constants which were adjusted for best fit: $G_s = 8 \times 10^{-7}$ mhos cm^{-2}, $G_{Al} = 10^{-11}$ mhos cm^{-2}, Al = 1 M/l. and 0·2 M/l., $Me^+ =$ 0·1 M/l., $K_{1,2} = 0{\cdot}1$, $E_3 = 2$ kcal/mol, $E_4 = -2$ kcal/mol, $K_{5,6} = 4 \times 10^{11}$, $n = 6$. The thickness of the hydrocarbon layer was assumed to be 50 Å.

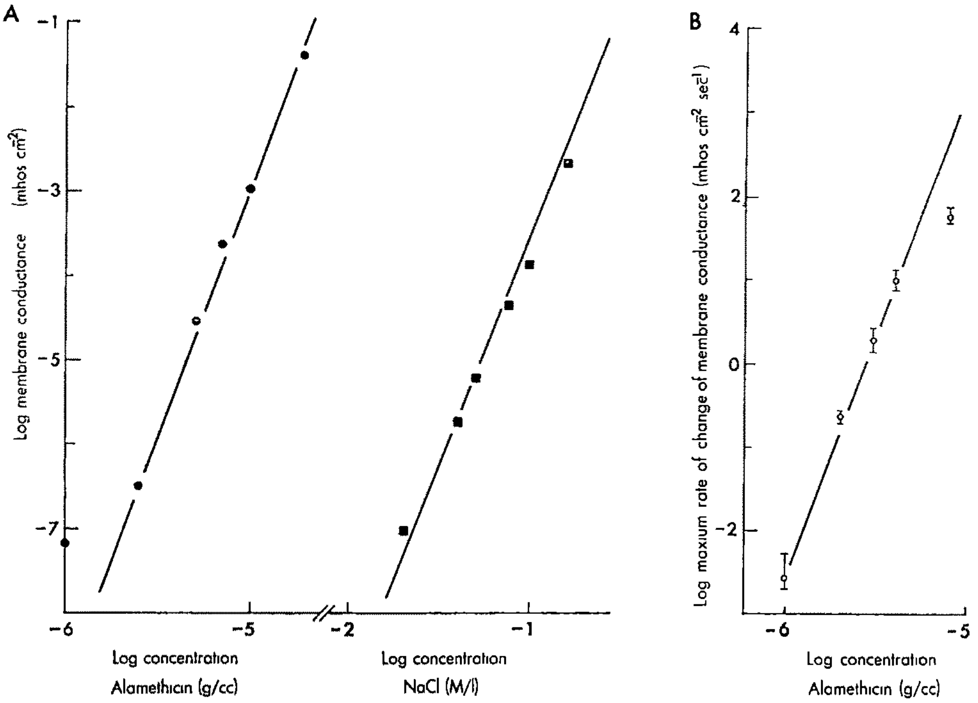

Fig 6 *A*, (Left) Relation between membrane conductance (I/V) and concentration of alamethicin in the aqueous phase at constant ion concentration (0 1 M sodium chloride) and constant voltage (60 mM) (Right) Relation between membrane conductance and concentration of sodium chloride in the aqueous phase, at constant alamethicin concentration (10^{-5} g/ml), and constant voltage (60 mV) All concentrations are identical in both aqueous compartments Membrane lipid composition as in Fig 1*A* The straight lines have slopes to the sixth power which are independent of membrane lipid composition and of the voltage as long as the conductances induced by alamethicin are much larger than the intrinsic membrane conductance These curves were each obtained from a single membrane *B*, Maximum rate of change of membrane conductance after a sudden displacement of the membrane potential by 100 mV (voltage clamp), as a function of the concentration of alamethicin Membrane in 0 1 M sodium chloride, both sides, membrane solution as in Fig 1*B*, temperature, 35° C The slope of the straight line again indicates a sixth power function Each point is an average of ten values obtained from ten different membranes The bars give the total scatter

This is the simplest interpretation for the origin of the bistability, and if it is assumed that the gating mechanism of the pure alamethicin system remains intact within the alamethicin–protamine complex then all the conditions are fulfilled for developing action potentials within the framework of the Hodgkin and Huxley theory[8] namely, that two gated conducting systems with appropriate time constants and different ionic selectivities act as parallel EMFS and variable resistive loads on each other This is the likeliest interpretation for the origin of the experimental action potentials

Although the nature of the underlying gating mechanism has not been resolved, some preliminary models can be considered A simple monovalent carrier mechanism can be excluded as inconsistent with the highly non-linear co-operative phenomena shown by alamethicin and EIM, and carriers composed of six or more alamethicin molecules having molecular weights of 11,000 or larger would be rather bulky items in terms of membrane dimensions Moreover, if these aggregates form complexes with compounds like protamine or polylysine having molecular weights up to 50,000, it seems doubtful whether they could retain the essential mobility of a carrier In addition, it has been pointed out[8] that in certain conditions carriers should develop measurable currents because of their own transient movements None has been found[8] For these reasons carrier mechanisms are not favoured at this time although their existence would not change the validity of the mathematical model or critical aspects of the discussion to follow

As an alternative, alamethicin might cause a reversible micellization of the bilayer structure Co-operative interactions between micelles to form channel domains or clusters could account for the non-linear effects Although channel domains may exist, however, it is at present considered more likely that the primary gating event results from the self-aggregation of the cyclopeptide component As discussed later, the properties of alamethicin resemble allosteric proteins which characteristically undergo polymerization in the presence of extraneous molecules and alamethicin exhibits a strong tendency to aggregate in both aqueous and non-aqueous solution It has also been found that most of the electrokinetic effects of alamethicin, except protamine interaction, can be induced in bilayers by amphophilic ion precipitants such as dipicrylamine which develop strong attractive forces between the organic moiety[10] accounting for their unique effects in aqueous solutions Furthermore, if the cyclic compounds do form ionic co-ordination complexes, we must assume that they and not lipid polar groups provide the immediate conduction sites for ions across the bilayer Finally, the invariance of the principal electrokinetic phenomena despite wide lipid variation gives additional support to this interpretation

We therefore tentatively suggest that through self-aggregation, or a change in aggregation state, alamethicin provides a series of sites bridging the bilayer, whatever lipid rearrangements may secondarily accompany such an effect

The enniatins and valinomycin, which develop large conductances but no gating effects, lack the functional side groups of alamethicin and, as depsipeptides, also lack every other nitrogen atom of the peptidic proton donor The enniatins, in fact, contain none because the remaining nitrogen groups are blocked by *N*-methylation Consequently, these compounds, as compared with the homodetic peptide, alamethicin, can form no more than half the number of peptide hydrogen bonds between rings of the type which stabilize the α-helix of linear proteins It is therefore conceivable that within the constraints imposed by the anisotropic hydrocarbon chains of the bilayer the additional intermolecular hydrogen bonds of alamethicin and the development of aggregates of tubular form resembling phage tail cores

At present the simplest interpretation of the fact that the kinetic order and molecularity of the reaction are both hexameric would be that the potential varies the concentration of alamethicin monomers and metal ions in the hydrocarbon region to form hexameric conducting units Because the conductance varies as the sixth power of the ionic strength even when extrapolated to zero voltage the conducting configuration is probably stabilized in part by ionic or ion dipole interactions as well as hydrogen ion bonding. Within this formulation EIM and alamethicin would differ only in having free energies of opposite sign for the monomer–hexamer transition, the former normally resting in the hexameric form, the latter in the monomeric form

The oligomers may exist in several alternative bond states which could account for the polarized nature of the conducting system If the hydrogen bonds were polarized from donor to acceptor, as they are in α-helices, they would lie in a particular direction across the membrane and a reversal of the field might cause a reversal of bond polarization which could explain the observed decrease in transient conductance This could occur with the existing set of channels or involve a complete dissembly of one set and reassembly of another set from the opposite side of the membrane In addition, or as an alternative, the side groups might be similarly polarized or exist in a number of inter- or intra-molecular (chelate) bond configurations (see Fig 4), or the rings may be stacked with their peptide bonds lying in the same or alternating senses around the rings, or the atoms of adjacent rings could be located in several alternative registers

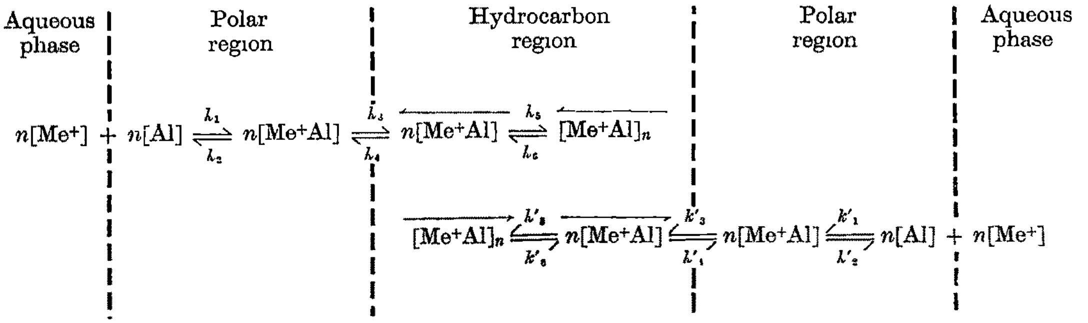
The idea of reversible bridge formation by an aggregate of six ions under the control of the membrane potential has already been suggested by Hodgkin and Huxley as one possible basis for action potentials in nerve[8] If we agree with them and make the following three assumptions, we can account quantitatively for the chief features of the chemical and electrokinetic findings

(1) In the absence of a large phase boundary, resting or applied membrane potential, the alamethicin molecules (Al) are primarily absorbed as monomers or possibly aggregates of a non-conducting type to the two polar regions of the bilayer In addition to the counterion of the carboxyl group a fraction of the rings carry an extra cation (Me$^+$) sequestered by the peptide carbonyls of the ring giving the total co-ordination complex a net positive charge. Only this fraction forms conducting oligomers This accounts for the fact that a positive voltage on the side of the membrane to which alamethicin has been added induces a larger increase in conductance than a negative voltage and that the conductance is a function of the ionic concentration to the sixth power

(2) An applied or resting potential, or an increase of the phase boundary potential caused by changing absorbates, ions or lipid, drives the monomers [Me$^+$Al] from the positive side into the hydrocarbon region where they aggregate as hexameric tubular channels, carriers or other aggregate form of a conducting nature (Me$^+$Al)$_n$ Because of these complex dynamics the distinction between carrier and channel concepts becomes blurred

(3) The intra-oligomeric bonds are polarized in one direction or the other normal to the plane of the membrane according to the sign of the potential The polarization sign, indicated by an arrow in equation (1), also dictates the direction of assembly and dissembly of the oligomer No transfer of monomers takes place from one polar region to the other, presumably because the oligomers are formed by sequential apposition of polarized monomers from only one side or because secondary lipid re-arrangements block this movement

These assumptions can be represented by the following simplified reaction scheme



Aqueous phase
Polar region
Hydrocarbon region
Polar region
Aqueous phase
n[Me+] + n[Al] ⇌(k1, k2) n[Me+Al] ⇌(k3, k4) n[Me+Al] ⇌(k5, k6) [Me+Al]n
[Me+Al]n ⇌(k'5, k'6) n[Me+Al] ⇌(k'3, k'4) n[Me+Al] ⇌(k'1, k'2) n[Al] + n[Me+]

(1)

The concentration of positively charged alamethicin monomers located in the polar region at zero potential [Me$^+$Al] is related to the concentration of metal ions [Me$^+$] in the aqueous phase and alamethicin [Al] in the polar region by

$$K_{12}\,[\mathrm{Me}^+] + [\mathrm{Al}] = [\mathrm{Me}^+\mathrm{Al}] \qquad (2)$$

where $K_{12} = k_1/k_2$ is the dissociation constant of the metal ion–alamethicin complex For simplicity, equation (1) neglects the distribution constant for [Me$^+$] between aqueous and polar regions as well as the dissociation and polymerization side reactions which may go on in each of the three regions

The fraction, p, of the charged monomers, [Me$^+$Al], driven from the polar region into the hydrocarbon region by the potential, V, is given by

$$p = k_3/(k_3 + k_4) \qquad (3)$$

in which k_3, k_4 are the rate constants for the transition into and out of the hydrocarbon region and are of the form

$$k_3,\ k_4 = A \exp E_{3,4} \pm z\ 11\ 5\ V/RT \qquad (4)$$

where E_3, E_4 are the activation energies in kcal/mol for the forward and backward transitions, z is the valence of the monomer, A is the collisional frequency constant and V is the membrane potential The concentration of oligomers, or channels, is then

$$[\mathrm{Me}^+\mathrm{Al}]_n = ([\mathrm{Me}^+\mathrm{Al}]p)^n K_{5\,6} \qquad (5)$$

where $K_{5\,6} = k_5/k_6$ is the equilibrium constant for the formation of channels from the monomer The membrane conductance, G_m, as a function of the potential, the concentration of alamethicin in the aqueous phase and the concentration of monovalent cations in the aqueous phase are then given by

$$G_m = G_0 + G_{\mathrm{Al}}\,K_{5\,6}\,([\mathrm{Me}^+]\,[\mathrm{Al}]\,K_{1\,2}\,p)^n \qquad (6)$$

where G_0 is the intrinsic conductance of the bilayer in the absence of alamethicin and G_{Al} is the conductance of the individual alamethicin oligomer.

With most lipids, $k_4 \gg k_3$, so that at low concentrations of alamethicin the resting conductance is equal to G_0 because there are only a few conducting oligomers. In this case it is sufficient to deal with one side of the reaction scheme only At higher concentrations, oligomers of both polarization signs appear at zero potential and those of one sign will be dissembled by the voltage while those of the opposite sign are simultaneously assembled The experiments indicate that $n = 6$ in all conditions examined so far, including variations of lipid composition, temperature and pH, and that $k_1 \ll k_2$ so that excess Me$^+$ can still regulate the concentration of [Me$^+$Al]

Some examples are calculated and compared with the experimental data in Fig 5 At low voltages the experimental values deviate from those predicted by equation (6), perhaps because the profile of the surface potential which determines the resting conductance is different from the potential profile caused by the applied voltage

The model assumes a causal relation between the high order of the conductance versus concentration and that of the conductance versus voltage functions This relation could be fortuitous and the channel closure could occur without disaggregation, for example, as a result of the statistical operation of six series gates formed by the glutamic residues blocking the ring opening through chelate formation But, in this event, additional and rather unlikely hypotheses would have to be introduced to account for the fact that the rates of gate operation also depend on the sixth power of the concentration of alamethicin Moreover, the state of low conductance approaches the intrinsic value of the conductance of the bilayer itself and, while this condition is easily met by total channel dissembly, in its absence effective ring blockage would be required

Within the framework of this model alamethicin resembles an allosteric protein in which the observed co-operative and modifier-substrate effects result from configurational changes which involved oligomeric systems Protamine and possibly the potential may act as allosteric modifiers of the ionic (substrate) conductance by controlling the monomer–oligomer transition, a typical ligand effect in regulatory enzymes This effect of protamine represents a type of chemical control over the ionic gating mechanism which might be elaborated into a mechanism for actively pumping ions against an electrochemical gradient Compounds containing high energy phosphate are common ligands of allosteric systems and in appropriate conditions a single phosphorylation reaction might induce the bond reversal or other oligomeric re-arrangement discussed earlier Because of the bond constraints in such systems perturbation of a terminal bond in a linear oligomer could sweep over the entire structure causing the vectorial ejection of 5 to 10 ions against an ion gradient

In fact, three lines of experimental evidence indicate a close relation between ion gates and ion pumps First, both are ion handling systems showing the same ion discriminating capabilities[11] known to occur only with macrocyclic compounds, and both seem to manipulate an unusually large number of ions (5 to 10) per elementary cycle[12]. Second, as with alamethicin in bilayers, ion pumps show homotropic ionic co-operative effects, heterotropic modifier-substrate interactions and large entropy changes characteristic of allosteric systems[13,14] Finally, preliminary data suggest some chemical similarities Ion pumps, phosphorylation reactions and the membrane properties of alamethicin or EIM are modified by chlorpromazine and promethazine[3,13,15], basic proteins[3,16], atabrine and octyl guanidine[3,17], all at concentrations of a few μg/ml Finally, ion pumps may be composed of five[18] or six[19] molecular sub-units The sub-units of both may have molecular weights of a few thousand and are exopeptidase insensitive[19], implying again that both contain ring compounds or blocked terminal groups as in gramicidin

An allosteric gate-pump mechanism for regulating ion movements across bimolecular lipid membranes may provide a system for carrying out cellular energy transformations because it has been shown in cells that electron transport, oxidative phosphorylation and ion movements are closely coupled[20] High energy electrons in the redox system, high energy phosphate bonds in ATP and the electrochemical energy of a transmembrane ion gradient can be taken as three equivalent energy forms which are interconverted in a symmetrical manner by the gate-pump system Six reversible energy transformations would then be predicted and the evidence suggests that all six have been observed. Thus either high energy electrons[21] or ATP[11] can generate an ion gradient, or an ion gradient can reduce the cytochromes[22] or form ATP[23] and the cytochromes can generate ATP[17] or ATP can reduce the cytochromes[24] The energy per ion varies with the electrochemical gradient but is usually 2 to 10 times smaller than the chemical energy units, that is to say, ATP or redox step The system, however, maintains a high efficiency by transporting five or more ions per unit of chemical energy This unusual stoichiometry requires a special molecular machinery to couple the disparate energies efficiently The ion handling and polarization properties of alamethicin suggest that a cyclopeptide hexamer sequestering six ions and capable of cycling between conducting and non-conducting states of polarized configuration could supply the necessary coupling machinery It would be necessary only for the same configurational cycle to be induced by each of the three energy forms Because of the mutual bond constraints in the oligomer a change induced in the bond state of one monomer, for example, by phosphorylation or a valence change of Fe^{++} to Fe^{+++}, could drive the entire oligomer into an alternative configuration of higher energy through a series of consecutive reactions across the membrane Conversely, because the bond energy in each monomer is a function of all the others, such a system may provide a way to lead off the configurational energy of the entire oligomer through one of its monomers to form a high energy phosphate bond These distributive characteristics would be particularly suitable for coupling reactions operating at different levels of unit energy as discussed earlier Conformational states[25] of cyclopeptide oligomers may therefore satisfy the requirements for the unknown metabolic intermediates[26] often designated as X, Y and $\sim X$, $\sim Y$ If so, then excitability phenomena, active transport processes and the key steps in the utilization of respiratory and radiation energy, that is, oxidative and photosynthetic phosphorylation, would all result from related modes of operation of a common mechanism located in cell membranes

We thank Dr George B Whitfield, jun , of the Upjohn Company, for the alamethicin

RNA in Mouse Cells exposed to Different Antigens

by
KAREL RASKA, jun *

New Brunswick, New Jersey

The behaviour of peritoneal cells in producing different species of RNA after exposure to different antigens is consistent with the idea that the potential to produce antibodies of varying specificity is inherited

THE finding that plasma cell tumours secrete a homogeneous protein, thought to be identical to a normal immunoglobulin produced in excess, has made it possible to determine the amino-acid sequence of the light chain sub-unit of the whole molecule[1-3]. Sequence analysis of light chains isolated from mice bearing several types of tumours reveals that approximately half of the molecule has a constant structural identity and that there are variations in sequence throughout most of the other half[4] At least three hypotheses have been proposed to explain the molecular mechanism by which immunoglobulins arise *in vivo* (*a*) Half of a single gene for antibody synthesis undergoes mutation during somatic development[5-7], (*b*) a single species of messenger RNA is misread during translation[8], and (*c*) the potential to produce antibodies of varying specificity is inherited in multiple genes, and antigens activate those genes appropriate for the synthesis of specific immunoglobulins[9]

In an attempt to test these hypotheses, we first reported[10] that new species of RNA† appeared in the mouse spleen after inoculation with sheep red blood cells (SRBC) The presence of this RNA was detected *in vitro* by hybridization with mouse DNA In further experiments, we sought to determine whether the formation of new species of RNA by the mouse was a non-specific response to immunization, or whether separate and distinct RNAs appeared after immunization with separate and distinct antigens

Peritoneal exudate cells (p e cells) were obtained from B_6AF_1 mice (Jackson Laboratories, Bar Harbor, Maine) or *CD*-1 mice (Charles River, Wilmington, Mass) Each of approximately 100 mice was injected intraperitoneally with 3-thioglycollate broth (Difco) Three days later the mice were killed and the peritoneal cavity of each mouse was rinsed with 5 ml of Eagle's medium (Grand Island Biologicals, without added serum) containing 100 u of penicillin, 50 μg of streptomycin and 0 5 u of heparin/ml The cells were centrifuged gently at 4° C and resuspended in fresh medium with the addition of 0 01 mCi/ml of tritiated uridine (Schwarz Bioresearch) Antigen was added‡, as indicated in the legends to the figures, and the cells were incubated in medium for 1 h at 37° C in a water bath equipped with a shaking device

After incubation the cells were centrifuged and the RNA was extracted from the pellet by the warm phenol method[11] DNA was extracted[12] from the spleens and thymus glands of B_6AF_1 mice and after heat denaturation was immobilized on membrane filters ('Millipore')[13] Hybridization occurred when the labelled RNA dissolved in 2 5 ml of 2 × SSC (SSC is 0 15 M sodium chloride and 0 015 M sodium citrate) was incubated with a filter containing DNA for 20 h at 65° C After incubation the filters were washed by passing 50 ml of 2 × SSC in one direction and then 50 ml of fresh 2 × SSC in the other direction The filters were then treated with 25 μg of RNase (Worthington, boiled before use) in 2 5 ml of 2 × SSC to remove non-specifically bound RNA[13] and then washed again. Scintillator (PPO, POPOP, toluene) was added to the dried filters and the remaining radioactivity was determined in a Packard 'Tri-Carb' liquid scintillation counter Peritoneal cells were separated into two populations—those which adhered to glass (more than 99 per cent macrophages) and those which did not adhere to glass (more than 95 per cent lymphocytes) The entire population was suspended in Eagle's medium and incubated in glass bottles for 3 h At the end of the incubation period, the cells which did not adhere to the glass were removed by decantation The cells which adhered were washed gently with fresh medium. Antigen was incubated with the adhering population for 1 h at 37° C, after which RNA was extracted as described previously

The cells which failed to adhere to glass were centrifuged gently and resuspended in fresh medium The population was then incubated at 37° C for 1 h with antigen before RNA was extracted

In studies involving molecular hybridization a saturation plateau results when increasing amounts of labelled RNA are added to a fixed amount of DNA in conditions which allow the formation of RNA DNA hybrids. This plateau is reached when all the available sites for hybridization in DNA are occupied with complementary species of RNA The number of counts which remain complexed with the DNA after removal of non-hybridized RNA is an index of the number of different molecular species of RNA which are present in the preparation It is independent of the specific activity of the preparation of RNA used for hybridization studies (A representative member of each species of RNA hybridizes to its complementary site, and so other members of that species are washed away The specific activity of each molecular species may differ, so that the specific activity of the whole preparation may vary for a wide range without affecting the c p m which remain with the filter after incubation with saturating amounts of labelled RNA)

The basis of an important control, involving cells incubated without added antigen, is the ability of unlabelled RNA to compete with labelled RNA for sites of hybridization This capacity for competition between two RNAs is an indication of the number of molecular species of RNA in common in the two preparations

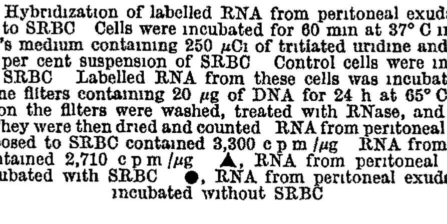

Fig 1 Hybridization of labelled RNA from peritoneal exudate cells exposed to SRBC Cells were incubated for 60 min at 37° C in 25 ml of Eagle's medium containing 250 μCi of tritiated uridine and 0 3 ml of a 10 per cent suspension of SRBC Control cells were incubated without SRBC Labelled RNA from these cells was incubated with membrane filters containing 20 μg of DNA for 24 h at 65° C After incubation the filters were washed, treated with RNase, and washed again They were then dried and counted RNA from peritoneal exudate cells exposed to SRBC contained 3,300 c p m /μg RNA from control cells contained 2,710 c p m /μg ▲, RNA from peritoneal exudate cells incubated with SRBC ●, RNA from peritoneal exudate cells incubated without SRBC

† We realize that some species of RNA may be present in amounts too small to be detected by molecular hybridizations and that "new" species may represent an increase in such species The term "new" is used for convenience only

‡ In general terms, a foreign material becomes an antigen only if it stimulates the formation of antibody In these experiments, we did not determine whether the cells exposed to "antigen" would eventually form antibody, hence the term "antigen" is used for convenience

Similarly, the relative capacity of two unlabelled RNAs to compete with one preparation of labelled RNA is an index of the number of molecular species in common between the two unlabelled preparations.

When filters containing mouse DNA were incubated with increasing amounts of RNA, a plateau was reached which was higher when the RNA was isolated from peritoneal exudate cells that were exposed to SRBC (Fig 1) This suggested that peritoneal exudate cells incubated with SRBC formed species of RNA that were not actively synthesized by control cells Experiments were carried out involving competition between labelled RNA from cells exposed to SRBC and unlabelled RNA from cells incubated with or without added sheep cells The results (Fig 2) indicate that unlabelled RNA from stimulated cells was a more efficient inhibitor than was RNA from unstimulated control cells

To determine whether different species of RNA formed after peritoneal exudate cells were exposed to different antigens, we carried out a series of reciprocal competition experiments between labelled and unlabelled RNAs from cells exposed to one antigen and labelled and unlabelled RNAs from cells exposed to a second antigen

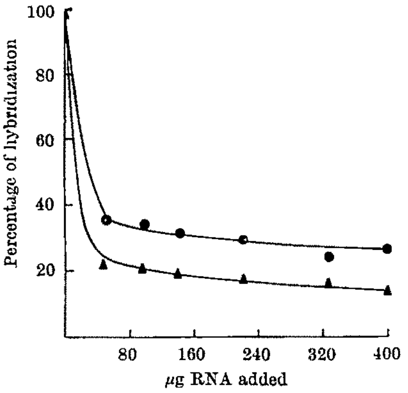

Fig 2 Competition for sites of hybridization by unlabelled RNA from either SRBC-exposed or control peritoneal exudate cells Tritiated RNA (40 μg) from peritoneal exudate cells exposed to SRBC was incubated as described with membrane filters containing 20 μg of DNA and varying amounts of unlabelled RNA from either control cells or cells exposed to SRBC After incubation the filters were treated as described previously ▲, Unlabelled RNA from peritoneal exudate cells incubated with SRBC ●, Unlabelled RNA from peritoneal exudate cells incubated without SRBC

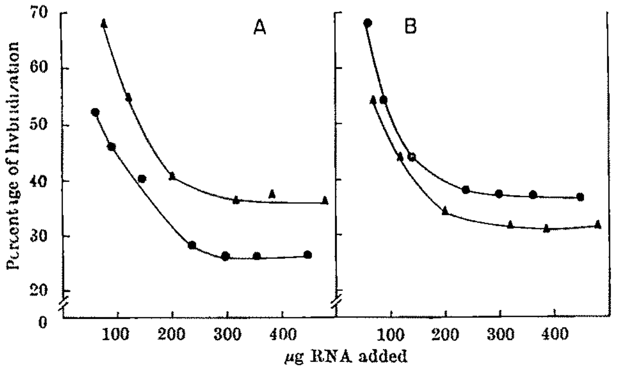

Fig 3 Competition for sites of hybridization by unlabelled RNA from either SRBC or CRBC-exposed cells *A*, Tritiated RNA (40 μg) from peritoneal exudate cells exposed to SRBC was incubated with filters containing 20 μg of DNA and varying amounts of unlabelled RNA from cells exposed to either SRBC or CRBC *B*, Other filters were incubated with 40 μg of labelled RNA from peritoneal exudate cells exposed to CRBC and varying amounts of unlabelled RNA from the same pools of either SRBC or CRBC-exposed cells ▲, Unlabelled RNA from peritoneal exudate cells incubated with CRBC ●, Unlabelled RNA from peritoneal exudate cells incubated with SRBC

Pools of labelled or unlabelled RNA were prepared from peritoneal exudate cells exposed for 1 h *in vitro* to either SRBC or chicken red blood cells (CRBC) Filters containing mouse DNA were incubated with labelled RNA prepared from cells exposed to SRBC and with increasing amounts of unlabelled RNA from cells exposed to either SRBC or CRBC Other filters were incubated with labelled RNA isolated from cells exposed to CRBC and increasing amounts of unlabelled RNA from the same pools obtained from cells exposed to either SRBC or CRBC The results (Fig 3) indicate that unlabelled RNA from specifically stimulated cells was a more efficient competitor for sites of hybridization than was unlabelled RNA from non-specifically stimulated cells. Similar results were found with RNAs from SRBC and cells stimulated with *E coli* (Fig 4)

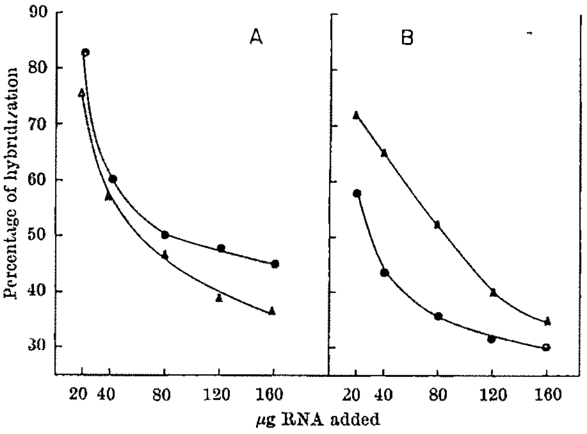

Fig 4 Competition for sites of hybridization by unlabelled RNA from cells exposed to either SRBC or *E coli* *A*, Tritiated RNA (50 μg) from peritoneal exudate cells exposed to SRBC was incubated with filters containing 20 μg of DNA and varying amounts of unlabelled RNA from cells exposed to either SRBC or *E coli* *B*, Other filters were incubated with 50 μg of labelled RNA from peritoneal exudate cells exposed to *E coli* and varying amounts of unlabelled RNA from the same pools of cells exposed to either SRBC or *E coli* ▲, Unlabelled RNA from peritoneal exudate cells incubated with SRBC ●, Unlabelled RNA from peritoneal exudate cells incubated with *E coli*

An additional control experiment with cells incubated without antigen was performed Filters containing mouse DNA were incubated with a fixed amount of unlabelled RNA from cells exposed to either SRBC or CRBC and increasing amounts of labelled RNA from cells exposed to SRBC. The results (Fig 5) indicate that unlabelled RNA from specifically stimulated cells was a more effective competitor for sites of hybridization than was unlabelled RNA from non-specifically stimulated cells The fact that unlabelled RNA from cells exposed to CRBC also competed suggests that many of the species of RNA in the two preparations were the same

These findings strongly suggest that some similar and some distinct species of RNA appeared after peritoneal exudate cells had been exposed to different antigens

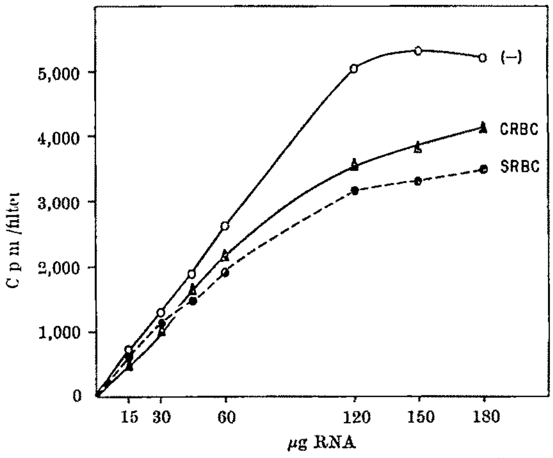

Fig 5 Competition for sites of hybridization by unlabelled RNA from cells exposed to either SRBC or CRBC Unlabelled RNA (120 μg) from cells exposed to either SRBC or CRBC was incubated for 24 h at 65° C with filters containing 20 μg of DNA Control filters were incubated without added RNA After incubation the filters were washed and varying amounts of labelled RNA from peritoneal exudate cells exposed to SRBC was added The filters were then incubated for an additional 24 h and washed Labelled RNA contained 12,600 c p m /μg

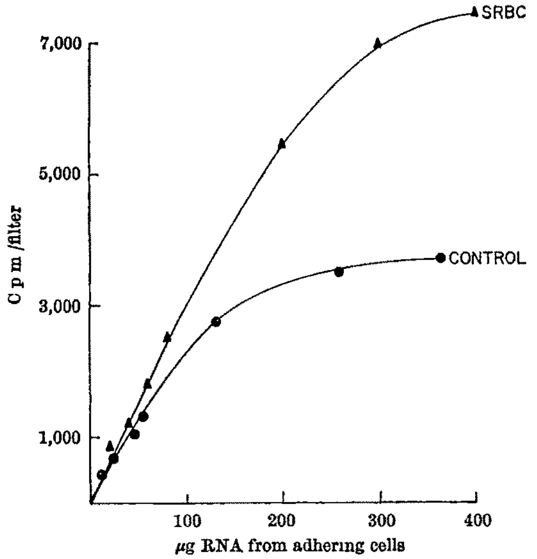

Fig 6 Hybridization of labelled RNA from peritoneal exudate cells which adhered to glass Cells were exposed to SRBC for 60 min in the presence of tritiated uridine After incubation the cells were washed and RNA extracted Control cells were incubated without SRBC. Varying amounts of labelled RNA were added to filters containing 40 µg of DNA ▲, RNA from cells exposed to SRBC, 10,450 c p m /µg ●, RNA from control cells, 6,300 c p m /µg

Peritoneal exudate cells were separated into populations which adhered or failed to adhere to glass Labelled or unlabelled RNA was extracted from both kinds of cells after incubation with antigen. Reciprocal competition experiments were performed between RNAs from cells exposed to either SRBC or CRBC. Similar experiments were performed between RNAs from cells exposed to SRBC or *E coli*

Cells which adhered to glass as well as cells which failed to adhere to glass synthesized new species of RNA exposure to antigen (Figs 6 and 7) Different species of RNA, however, were not found when the adhering cells were incubated with different antigens (Table 1) Also, different species of RNA were not found after adhering cells had been exposed to either SRBC or *E coli* On the contrary, different species of RNA were detected after the non-adhering cells had been exposed to either SRBC or CRBC (Fig 8). Similar results were obtained when non-adhering cells were exposed to either SRBC or *E. coli*

The role of these antigen-stimulated species of RNA in the immune response remains to be determined They were detected in cells which did not adhere to glass (consisting predominantly of lymphocytes) One of the principal functions of lymphocytes is the synthesis and release of antibody. Thus the species of RNA formed in these cells may play an essential part in antibody formation Cells which adhered to glass, consisting of more than 99 per cent macrophages, synthesized new but not antigen-specific species of RNA.

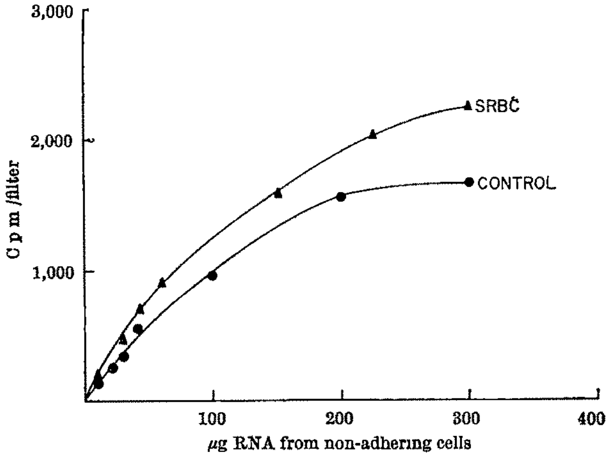

Fig 7 Hybridization of labelled RNA from peritoneal exudate cells which did not adhere to glass Cells were exposed to SRBC for 60 min in the presence of tritiated uridine After incubation RNA was extracted, and hybridization was performed as described ▲, RNA from cells exposed to SRBC, 7,100 c p m /µg ●, RNA from control cells, 6,100 c p m /µg

Table 1 HYBRIDIZATION OF RNA FROM CELLS WHICH ADHERED TO GLASS IN THE PRESENCE OF COMPETING RNA

Labelled RNA from cells exposed to	Experiment	Percentage hybridization with competing RNA from cells exposed to SRBC	CRBC
SRBC	1	35	36
(*A*)	2	44	42
	3	32	32
CRBC	1	26	27
(*B*)	2	45	46
	3	37	36

Each experiment was performed as a competition for sites of hybridization between labelled and unlabelled RNAs from the cells after incubation with antigen (*A*) Competition between labelled RNA from adhering cells exposed to SRBC and unlabelled RNA from adhering cells exposed to either SRBC or CRBC. (*B*) Competition between labelled RNA from adhering cells exposed to CRBC and unlabelled RNA from either of the same two pools used in (*A*)

Peritoneal exudate cells from *CD*–1 mice were incubated in Eagle's medium for 3 h at 37° C in glass bottles After incubation the non-adhering cells were removed and the adhering cells were incubated for an additional hour with either SRBC or CRBC Labelled RNA from such cells was prepared in a similar manner except that 0 1 mCi/ml of tritiated uridine was added to the incubation medium The results of three separate experiments are given Labelled RNA (20 µg) and at least 180 µg of unlabelled RNA were used in each experiment The filters contained 20 µg of DNA

Gottlieb *et al*[14] reported that immunogenic RNA from macrophages which formed a complex with phage was not unique for a given antigen This RNA was thought to be present in the cell before the addition of phage antigen Our findings—namely, that the adhering population formed new, but not different, species of RNA—are consistent with this report It is reasonable to suppose that the new species we detected are devoted to other cell functions, such as the formation of degradative enzymes Others have examined the immunogenicity of RNA-antigen complexes Askonas and Rhodes[16] and Friedman *et al*[17] concluded that a trace of the original antigen was present in the RNA fractions active in stimulating an immune response *in vitro* Youmans and Youmans[18] reported that RNA extracts of tubercle bacilli stimulated immunity when administered to normal mice before challenge

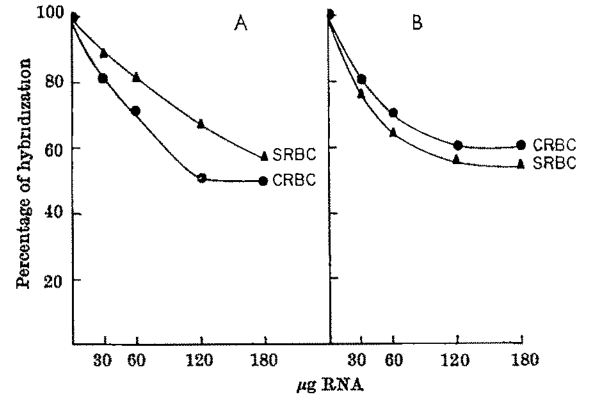

Fig 8 Reciprocal competition between unlabelled RNAs from peritoneal cells which did not adhere to glass Cells from the suspension used in the experiment reported in Fig 7 were incubated for 1 h with either SRBC or CRBC as described *A*, Labelled RNA (30 µg) from non-adhering cells exposed to CRBC was incubated with membrane filters containing 10 g of DNA from the spleens of mice and increasing amounts of unlabelled RNA from cells exposed to either SRBC or CRBC *B* Labelled RNA (30 µg) from non-adhering cells exposed to SRBC was incubated with membrane filters containing 10 g of DNA from the same preparation used in (*A*) and increasing amounts of unlabelled RNA from the same pools used in (*A*)

Reports from several laboratories indicate that RNA with properties of messenger converts otherwise normal cells to specialized function. Adler *et al*[19] found that RNA from rabbit peritoneal cells of *A4*/*A4* allotype exposed *in vitro* to antigen converted non-immune cells from rabbits of *A5*/*A5* allotype to form an antibody which was inactivated by anti-*A4* antiserum. Segal *et al*[20] and Mansour and Niu[21] reported that uterine tissue from immature rats was converted to a form which looked like tissue that was stimulated by oestrogen after it was exposed to RNA from mature rat uteri Fujii and Villee[22] found similar results with RNA from androgen-stimulated tissues. In both laboratories the preparations were thought to be free of residual hormone. Cohen *et al.*[23] reported that RNA from spleens of immunized mice converted a small proportion of non-immune cells to a form producing antibody The activity of the RNA extracts was unaffected by proteases and amylases Thus it may be that two types of intercellular stimulatory effects occur an effect based on RNA which is associated with antigen, and an effect based on information containing RNA free of antigen

On the basis of these experiments, we can make two additional suggestions on the origin of antigen-stimulated RNAs (1) The proportion of peritoneal lymphocytes which responded *in vitro* to antigen was probably large It is unlikely that sufficient unique RNA to have been detected would have arisen from the few stem cells which responded to antigen (2) The information for the synthesis of these RNAs was present in a large proportion of normal mouse DNA The DNA used in these experiments was obtained from non-immune mice These results are most consistent with the hypothesis that the potential to produce antibodies of varying specificity is inherited and not acquired through mutational processes thought to occur throughout somatic development Further evidence for this point rests on the demonstration that these unique species of RNAs are messengers for the synthesis of immunoglobulins

Toxicity of Pyrrolizidine Alkaloids

by

A. R. MATTOCKS

Toxicology Research Unit,
MRC Laboratories,
Woodmansterne Road,
Carshalton, Surrey

A new class of metabolite, with a pyrrole-like structure, has been demonstrated in the tissues of animals poisoned by pyrrolizidine alkaloids. There is some correlation between the degree of hepatotoxicity and the amount of "pyrrole" found in the liver Evidence has been found of the types of reactions such metabolites might undergo with tissue constituents.

CERTAIN pyrrolizidine alkaloids, such as heliotrine (I), lasiocarpine (II) and retrorsine (III), have long been known to cause chronic liver poisoning in animals, and the pathology has been well described[1,2] Progressive liver damage has been induced experimentally in rats by single doses of certain alkaloids[3,4]

Usually the most hepatotoxic alkaloids are cyclic diesters, like retrorsine (III) and seneciomine (IV) Higher doses of lasiocarpine (II) and still more of heliotrine (I) are needed to give similar effects, while supinine (V) is even less hepatotoxic[2] Some alkaloids, especially fulvine (VI) and monocrotaline (VII), frequently cause lung as well as liver lesions[4-6]

In contrast to the pathological studies, very little progress has been made in elucidating the mechanism by which these alkaloids exert their toxic effects A requirement for hepatotoxicity seems, *inter alia*, to be the allylic ester function[7] Thus rosmarinine (VIII), platyphylline (IX), and the amino-alcohol retronecine (X), among other alkaloids, are not hepatotoxic Culvenor, Dann and Dick[8] have suggested that the "toxic reaction" with cell constituents is an alkylation, based on the known tendency of the allylic ester group to undergo alkyl–oxygen fission

These alkaloids, however, are not notable as alkylating agents, and their chemical reactivity is usually of a low order, being limited to hydrolysis of the ester linkages and to readily reversible *N*-oxidation. The *N*-oxides display a toxicity which is similar to, but sometimes weaker than, that of the corresponding bases Neither the alkaloids nor their *N*-oxides respond in normal conditions to tests for alkylating agents, such as those employing 4(*p*-nitrobenzyl)pyridine[9] or 4-picoline[10] Nevertheless, it is hard to see how the alkaloids could exert their toxic effects without undergoing reaction with cell constituents. The chemically unreactive hepatocarcinogen dimethylnitrosamine (XI), the early effects of which on the liver are very similar to those caused by the pyrrolizidine alkaloids[11], is known to be metabolized to a reactive alkylating species which methylates proteins and nucleic acids *in vivo*[12] It is tempting to suppose that those pyrrolizidine alkaloids which damage the liver are also metabolized in that organ to a highly reactive intermediate. Some of this metabolite might in certain conditions be transported to the lungs or beyond This has been suggested[5] as an explanation for the lung lesions caused by fulvine

We have found evidence of metabolites from certain pyrrolizidine alkaloids which can be demonstrated in liver and other tissues after the alkaloids themselves have ceased to be detectable This evidence, and the nature and type of reactivity of such metabolites, is discussed here.

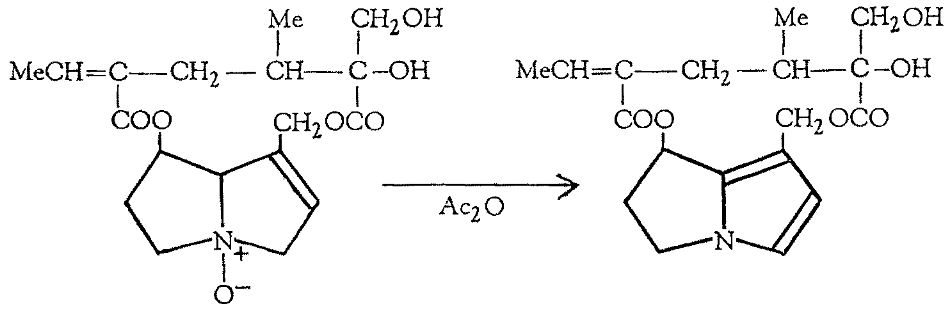
A procedure for the spectrophotometric determination of unsaturated pyrrolizidine alkaloids, recently described[13], involves dehydrogenation of the alkaloids—by treating their *N*-oxides with acetic anhydride—to pyrrole-like derivatives which give colours with a modified Ehrlich reagent (4-dimethylaminobenzaldehyde). An example is the conversion of retrorsine *N*-oxide (XII) to (XIII). Derivatives like (XIII) will for convenience be termed "chemical pyrroles". Usually, "chemical pyrroles" are only formed from alkaloids which have unsaturation in the basic moiety, that is, a 3-pyrroline ring. This structural feature is also present in all the markedly hepatotoxic alkaloids. It has now been found that similar (but not necessarily identical) derivatives are formed *in vivo* by metabolism of pyrrolizidine alkaloids. These "metabolic pyrroles" are detectable in the urine and tissues of rats dosed with pyrrolizidine alkaloids by the formation of mauve or magenta colours after warming with Ehrlich reagent. Such colours are not given by the alkaloids themselves or by their *N*-oxides.

Pyrroles in Urine

While measuring excretion of bases and *N*-oxides in the urine of rats which had been injected intraperitoneally with pyrrolizidine alkaloids using the new estimation



XII XIII

procedure[13], it was found that the urine gave a magenta colour when treated with Ehrlich reagent, and it was established that this was caused by metabolites of the alkaloids (my unpublished work). The alkaloids and their N-oxides did not undergo chemical decomposition to pyrrole derivatives when incubated for several days with rat urine Similar pyrroles were not found in the urine of rats the livers of which had been damaged by single doses of dimethylnitrosamine (given intraperitoneally) or by intravenous beryllium sulphate The "metabolic pyrroles" did not give reactions characteristic of urobilinogen or porphobilinogen[14]

Table 1 RECOVERY OF ALKALOID AND METABOLITES FROM URINE OF 6 × 150 G MALE RATS GIVEN RETRORSINE, 60 MG/KG, INTRAPERITONEALLY

Time after dosing (h)	Percentage recovered Alkaloid	N-oxide	"Pyrroles"
0–3 5	8 6	10 8	4 1
3 5–7	0 9	1 2	3 0
7–24	1 1	1 3	5 3
24–48	0 1	0 2	1 8
Totals	10 7	13 5	14 2

Results are percentage of dose given, calculated as alkaloid

With all the pyrrolizidine alkaloids tested, excretion of unchanged alkaloids and of N-oxides after intraperitoneal injection was rapid and had almost finished within 24 h Excretion of "metabolic pyrroles" varied with the alkaloid, but they usually reached a maximum a little later than the alkaloids and N-oxides Typical figures for retrorsine are given in Table 1 The amount of "metabolic pyrroles" excreted is of the same order as the amounts of unchanged alkaloids and of N-oxide "Metabolic pyrroles" excreted in the urine of animals given other alkaloids are listed in Table 2 Like the "chemical pyrroles", they formed red derivatives in the presence of strong acids

That the "metabolic pyrroles" were not the same as the "chemical pyrroles" derived from the same alkaloids was evident from differences in the absorption spectra of the colours formed with Ehrlich reagent The curves were always similar, but they were displaced in wavelength by a few millimicrons (Fig 1) "Metabolic pyrroles" from hepatotoxic alkaloids always showed a shift to higher wavelength compared with the "chemical pyrroles", whereas the non-hepatotoxic rosmarinine showed a slight drop in wavelength Similar wavelength shifts were observed with "metabolic pyrroles" formed *in vitro* (below)

Pyrroles in Organs *in vivo*

When rats were dosed, orally or intraperitoneally, with retrorsine (III), then killed after various times, it was possible to detect "metabolic pyrroles" in several organs, but especially in the liver The simplest way was to chop the tissues into small pieces, rinse them in water and in ethanol, homogenize them in absolute ethanol and centrifuge the homogenate The alcoholic liquor gave practically no Ehrlich reaction The residue was shaken with a modified Ehrlich reagent containing more acid than the usual reagent to overcome the buffering action of the tissues, then heated for 1 or 2 min at 80°–95° C (The reagent contained 3 g of 4-dimethylaminobenzaldehyde in 60 ml of absolute ethanol and 40 ml of 14 per cent methanolic boron trifluoride) The reagent was decanted and replaced with clean ethanol The presence of pyrroles was shown by a mauve colour in the suspended solids and often in the decanted reagent In these conditions, the liver of a rat given 30–100 mg/kg of retrorsine, and killed 0 5–12 h later, was stained mauve, whereas a control liver (untreated animal) was colourless The colour was detectable 5 min after dosing, reached a maximum probably between 2 and 5 h, and decreased until it was barely detectable at 45 h (Fig 2).

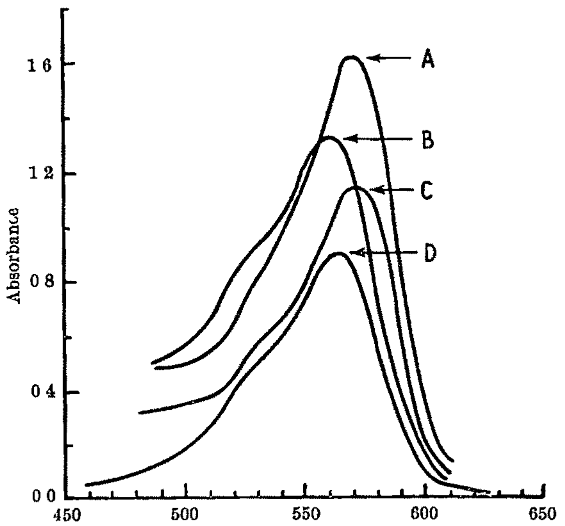


Fig 1 Absorption spectra of colours from Ehrlich reagent and "pyrrole" derivatives *A*, "Metabolic pyrrole" from lasiocarpine, *B*, "metabolic pyrrole" from rosmarinine, *C*, "metabolic pyrrole" from retrorsine, *D*, "chemical pyrrole" from retrorsine The "metabolic pyrroles" were from rat urine samples

Another method of demonstrating the colour in liver was to make thin slices, fix them in alcohol and heat them for a few minutes in the Ehrlich reagent, which was then replaced with clear alcohol This gave strongly coloured slices from retrorsine-treated animals compared with almost colourless controls The colour was also visible in sections prepared in the freezing microtome, but the intensity was not sufficient for it to be used as a histochemical stain

The metabolite in liver responsible for the Ehrlich reaction was demonstrable after the fresh tissue had been stored in a deep-freeze for at least 2 weeks, and also in ethanol-fixed slices or in ethanolic homogenates after a similar time That it was firmly bound to tissue constituents was shown by the failure either of ethanol or of isotonic aqueous media to extract it from liver to any great extent

An attempt to determine the distribution of "metabolic pyrroles" in subcellular liver fractions was made as follows A male rat was given retrorsine (140 mg/kg),

Table 2 "METABOLIC PYRROLES" FROM A NUMBER OF PYRROLIZIDINE ALKALOIDS, DETECTED IN RAT URINE AND LIVER *in vivo* AND IN LIVER SLICES *in vitro*

100–120 g male rats used

Alkaloid	Rough relative hepatotoxicity	"Pyrroles" in urine Dose of alkaloid given (mg/kg)	Percentage of dose excreted as "pyrroles" in 24 h	"Pyrroles" in liver *in vivo* Dose of alkaloid given (mg/kg)	Mauve colour (2–5 h)	"Pyrroles" in liver slices *in vitro* In slices	In medium (based on absorbances at 570 mμ)
Retrorsine (III)	+ + + + + +	60	12 4	50	+ + +	+ + + +	3 8
Retrorsine N-oxide (XII)	+ + +	60	3 6	60	+	+ + +	2 1
Monocrotaline (VII)	+ + + +	60	6 7	60	+ +	+	1 3
Senecionine (IV)	+ + + + +	60	7 1	50	+ + +		
Lasiocarpine (II)	+ + + +	60	8 5	100	+ + +	+ + + + +	6 3
Heliotrine (I)	+ +	150	2 1	250	+	+	1 0
Supinine (V)	+	150	1 2	250	+	+	1 2
Rosmarinine (VIII)	0	60	8 3	200	0	+ + +	17
Retronecine (X)	0	200	0 2	250	0	0	0

This table is explained in the text

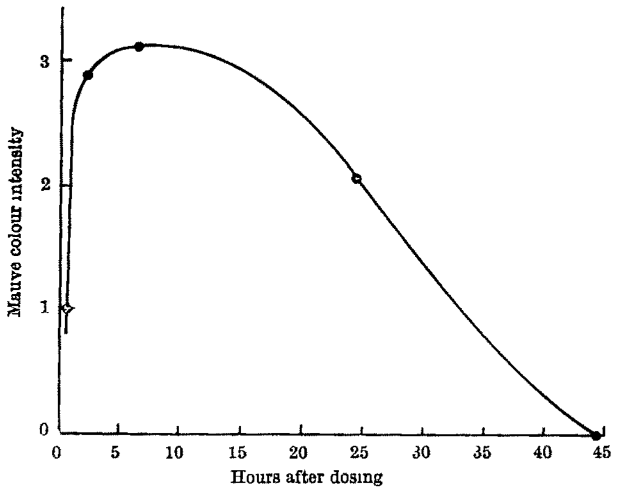

Fig 2 Build-up of Ehrlich-positive material in liver of rats injected with retrorsine (30 mg/kg) and killed after various times. Based on visual estimates of colour intensity.

intraperitoneally, and killed 1 h later. The liver was homogenized and fractionated in ice cold 0 3 M sucrose[15] Each solid fraction was treated with absolute ethanol and centrifuged, and the residues were heated with the modified Ehrlich reagent Mauve colours were observed in all the solids and in the reagent liquors from the debris (including nuclei) and microsomal fractions (λ_{max} 570 mμ) The solid debris and microsomal fractions were stained more strongly than the mitochondria or soluble proteins The ethanol supernatants gave no Ehrlich reactions

Other pyrrolizidine alkaloids also gave rise to "metabolic pyrroles" in the liver, as shown in Table 2 Some correlation between the strengths of colour and the hepatotoxic potency of the alkaloids is apparent in most cases Livers of rats treated with comparable doses of dimethylnitrosamine showed no colour with Ehrlich reagent

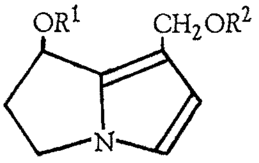
"Metabolic pyrroles" were sometimes detected in other organs The lung was the principal organ affected The colour, though much weaker than that in the liver, sometimes persisted after the liver colour was no longer apparent The staining of the heart, spleen and kidneys (but not the small intestine), 4 h after a large dose of monocrotaline, showed that the metabolite could be retained in these, too, in small amounts It may be pointed out that renal lesions have been found in rats given monocrotaline[6], while slight changes in the spleens and possibly hearts of rats were found after fulvine poisoning[5]

Formation of "Metabolic Pyrroles" *in vitro*

The staining of livers taken from animals dosed with pyrrolizidine alkaloids could be reproduced *in vitro*, using liver slices from normal rats Slices (about 0 25 g) were shaken at 37° C in 2 ml of Krebs Ringer phosphate[16] containing glucose (0 3 per cent w/v), but no added co-factors, in an oxygen atmosphere The alkaloids (500 μg) were added to the medium After 3–5 h the medium was decanted and the slices were washed with alcohol and heated with the modified Ehrlich reagent in the way already described, and colour changes were observed The aqueous media were diluted with alcohol, centrifuged, and the supernatants heated with Ehrlich reagent In most cases, colours similar to those of the slices were observed, and rough quantitative comparisons could be made (Table 2) Pyrroles were not formed by portions of lung tissue in similar conditions

"Chemical Pyrrole" Derivatives

The analytical method for determining unsaturated pyrrolizidine alkaloids[13] involves dehydrogenation of the alkaloids by heating their *N*-oxides with acetic anhydride This was extended to a preparative scale with modified conditions. Retrorsine *N*-oxide was treated at 50° C with acetic anhydride for 1–2 min, then with excess methanol containing sodium carbonate for 5 min Among the products was a petroleum-soluble fraction which was shown by chemical, chromatographic, infrared, nuclear magnetic resonance and mass-spectrographic evidence (which will be described elsewhere) to be a mixture (i) of (XIV), (XV) and (XVI) Aqueous alkaline hydrolysis of (i) converted (XIV) to (XV), leaving a mixture (ii) containing (XV) and (XVI) Both the mixtures (i) and (ii) gave strong Ehrlich reactions and decomposed instantly in acids to give red polymers



XIV $R^1 = CH_3$, $R^2 = CH_3CO$
or $R^2 = CH_3$, $R^1 = CH_3CO$

XV $R^1 = CH_3$, $R^2 = H$
or $R^2 = CH_3$, $R^1 = H$

XVI $R^1 = R^2 = CH_3$

The toxicities to rats of mixtures (i) and (ii) are summarized in Table 3 It is apparent that (i) is a powerful toxin, acting directly on the tissues with which it comes into contact Because (ii) is less toxic than (i), it seems that the principal toxic component is (XIV) The non-toxicity of these mixtures when given orally is understandable, for probably the compounds are rapidly decomposed on contact with stomach acid

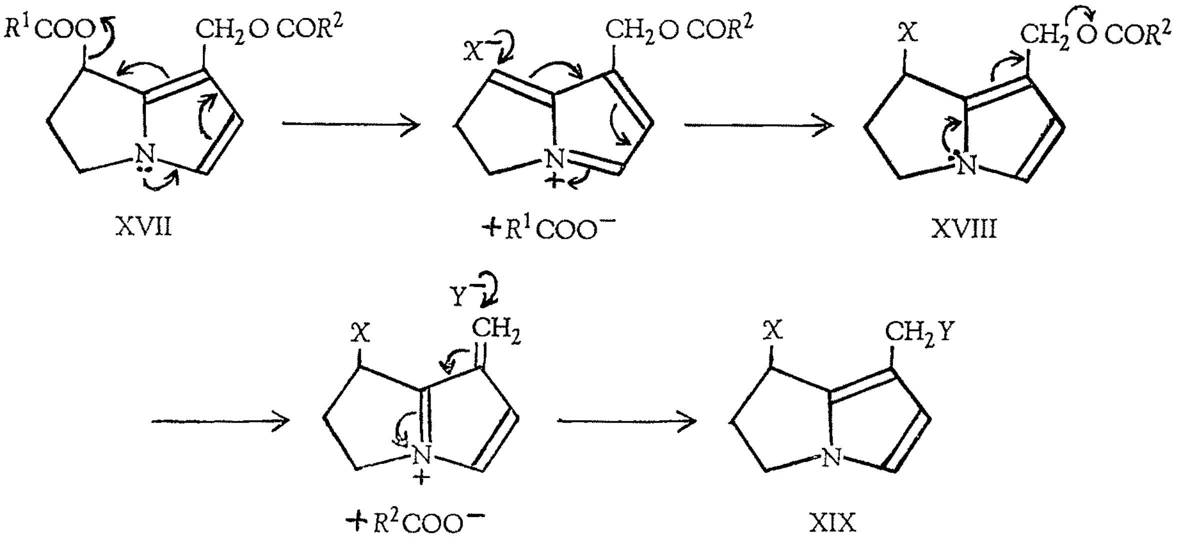
Table 3 TOXIC EFFECTS OF SINGLE DOSES OF SEMI-SYNTHETIC "PYRROLE" MIXTURES IN MALE RATS

	Route of administration and dose range		
Mixture	Oral 40–80 mg/kg	Intraperitoneal 25–60 mg/kg	Intravenous 20–40 mg/kg
(i)	No action	Severe local irritation. Peritonitis	Lung damage at 4–5 weeks typical of that caused by monocrotaline and fulvine
(ii)	—	—	No action

The course of poisoning and the striking pleural effusions seen at post-mortem in rats given a single intravenous dose of (i) are of particular significance, because they closely resemble those seen in rats 4–5 weeks after a single dose of monocrotaline or fulvine[5] The pathology will be described in detail elsewhere (unpublished results of Barnes, Butler and Mattocks)

Implications of the Results

The results summarized in Table 2 show that certain metabolites formed *in vivo* from a number of pyrrolizidine alkaloids have the following properties (*a*) They give magenta colours with Ehrlich reagent (*b*) In their reactions with acids and in the spectra of the Ehrlich derivatives they are similar to, but not identical with, the "chemical pyrroles" which can be prepared by dehydrogenating the same alkaloids (*c*) The "metabolic pyrroles" are partly excreted in urine, but some are also bound strongly to the tissues of the liver and to a decreasing



XVII $+R^1COO^-$ XVIII

$+R^2COO^-$ XIX

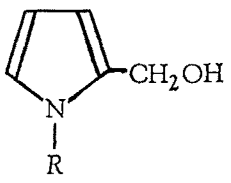
extent, the lung and other organs, for 48 h or more after being formed (*d*) With the exception of rosmarinine (which is discussed later), there is a rough correlation between the hepatotoxicity of the alkaloids[*] and the amounts of pyrroles to which they give rise *in vivo*

The following hypothesis is consistent with these results The alkaloids themselves are not hepatotoxic A proportion of the alkaloid (depending on its structure) is metabolized in the liver (by a process amounting to dehydrogenation) to a pyrrole-like derivative which has one or more highly reactive (electrophilic) centres in addition to its pyrrole-like properties This metabolite reacts rapidly with certain nucleophilic tissue constituents, both soluble and insoluble, forming "bound pyrroles" in which the high reactivity is lost but the pyrrole function remains Soluble "bound pyrroles" are either eliminated in urine or possibly adsorbed on local macromolecular sites A proportion of the reactive metabolite may be carried in the bloodstream to the lungs or beyond, to react and form "bound pyrroles" in these organs

Thus the metabolites detected in the urine and in the tissues of animals poisoned with pyrrolizidine alkaloids are soluble and insoluble "bound pyrroles", respectively

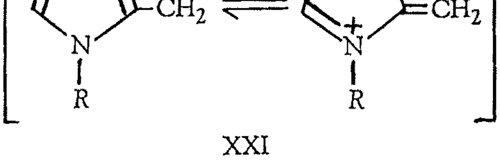
That the "metabolic pyrroles" consist of covalent compounds of alkaloid metabolites with various tissue constituents is not yet proved, but there is good circumstantial evidence The present results can be compared with the early experiments of Miller and Miller[17], who found that metabolites of the carcinogen *p*-dimethylaminoazobenzene were bound tightly to cellular constituents in the liver

Clues to the chemical nature of the reactive metabolite, and of any "toxic reaction" which it might undergo with tissue constituents, are provided by experiments with "chemical pyrrole" derivatives The cytotoxicity of compounds of type (XIV) has particular significance for the hypothesis that pyrrole-like derivatives are responsible for pyrrolizidine alkaloid toxicity Of special importance is the observation that a single dose of the mixture (i) (XIV+XV+XVI), administered intravenously, can cause a delayed lesion in the chest of the same kind as that produced by a single larger dose of fulvine or monocrotaline given by mouth A severe irritant effect is evident after intraperitoneal administration, and this may indicate that the pyrrole derivative does not survive long enough to reach the liver by the blood stream What might be the local effect if only a small amount of a similar compound were to be released metabolically within the liver cell can be appreciated



XX R=H or CH_3

The mode of preparation of the mixture (i) indicates the ease with which methanol and acetate (CH_3COO^-) can react with (probably) (XIII), with loss of the original acid moiety of the alkaloid The ester groups in retrorsine (III) are relatively resistant to hydrolysis by acyl–oxygen fission In contrast, the ester linkages in (XIII) can be broken by unimolecular alkyl–oxygen fission, and thus rendered highly reactive, being unaffected by the steric hindrance associated with the S_N2 reaction It is emphasized that both the ester groups of a diester alkaloid can be thus activated when the 3-pyrroline ring is converted to a pyrrole ring This is illustrated by the reaction of the nucleophiles X^- and Y^- with the pyrrole derivative of a diester alkaloid (XVII) to form (XVIII) and then (XIX) (not necessarily in that order) In (XIX), both X^- and Y^- have been "alkylated" by the pyrrole moiety, which can thus be regarded as a bidentate alkylating agent The special properties attributed to (XVII) are paralleled by the behaviour of 2-hydroxymethyl pyrroles (XX) Silverstein *et al*[18,19] found it impossible to prepare derivatives of these alcohols, owing to their ability to form resonance-stabilized cations (XXI) (ref 20) Also comparable are the α-hydroxy amines (pseudo-bases)[21] (XXII), in which the hydroxy group is unusually labile for similar reasons, and can exchange with alkoxy groups in mild conditions In fact, the hydroxymethyl pyrrole derivatives can be regarded as conjugated pseudo-bases



XXI

---

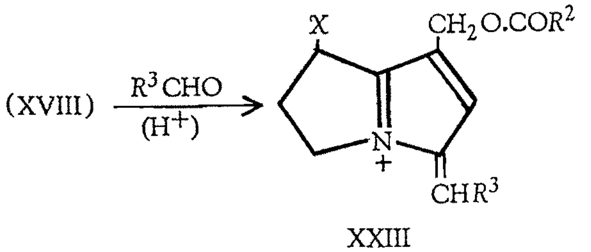
[*] Designations of hepatotoxicity are necessarily crude, being derived from results from various sources Short-term LD_{50} figures, where available, are not necessarily a reliable guide to chronic hepatotoxicity[7], so designations of the latter are rather based on comparisons of the doses of different alkaloids usually stated to be needed to produce typical long-term effects in rats

$$R_2N.CH_2OH \underset{HOH(H^+)}{\overset{R^1OH}{\rightleftharpoons}} R_2N.CH_2OR^1$$

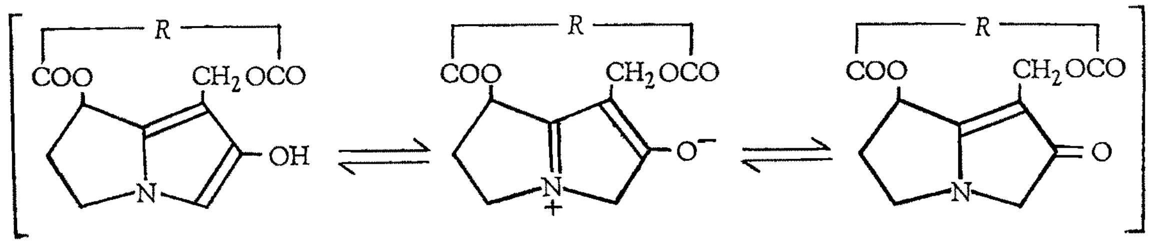
XXII

the esters of which, as exemplified by the "chemical pyrroles", are accordingly highly reactive Seen in this light, it is possible that, in certain conditions, "alkylations" caused by such pyrroles may be reversible. (This again might suggest possibilities for interference with biochemical systems)

Another unusual feature of this system is the further possibility of reaction of electrophilic groups at the α-position of the pyrrole ring This is a normal reaction of pyrroles, and the Ehrlich reaction is an example. Thus (XVIII) could react with an aldehyde to give (XXIII) Side effects of this would be to stabilize the alkylation bond to *X*, and also to de-activate the alkylating ability of the remaining ester group, as well as to prevent the subsequent detection of the derivative with Ehrlich reagent



XXIII



XXIV

There is direct evidence that the "chemical pyrroles" can act as alkylating agents The mixture (i), mentioned earlier, and also (XIII) and similar derivatives (but not the parent alkaloids or *N*-oxides), give positive reactions as alkylating agents using 4(*p*-nitrobenzyl)-pyridine[9] or 4-picoline[10]. In addition, preliminary experiments have shown that (XIII) reacts with bases such as *cyclo*hexylamine, pyrrolidine and guanosine to form compounds which give coloured Ehrlich derivatives the absorption maxima of which are higher than that of the starting material, and similar to the "metabolic pyrroles" Thus the elevated λ_{max} of "metabolic pyrroles" compared with the corresponding "chemical pyrroles" could be the result of similar alkylation-type reactions *in vivo*

The alkaloid rosmarinine (VIII) presents an unusual case Although the concentration of "metabolic pyrroles" found in urine is usually an indication of the amount of reactive metabolite initially formed in the liver, it is the "bound pyrroles" in liver and other tissues which are more likely to be of importance in accounting for the toxicity of the alkaloids Thus, although rosmarinine gives rise to large amounts of urinary "pyrroles", no "bound pyrroles" are found in the liver *in vivo*, and this could account for the lack of hepatotoxicity of this alkaloid (The "bound pyrroles" found in liver slices treated with rosmarinine *in vitro* (Table 2) may result from differences in metabolism between the two systems, or to the lack of a flushing blood flow in the slices.) Furthermore, the pyrroles from rosmarinine differ from those from other alkaloids, such as the related senecionine (IV), as shown by the differences in the absorption maxima of their Ehrlich derivatives This might be due to the retention of the β-hydroxy group in the pyrrole ring, giving rise to tautomeric forms (XXIV) and thus considerably reducing the alkylating power of the ester groups

The gradual disappearance of "bound pyrroles" from tissues may be accounted for in several ways Adsorbed pyrroles might be slowly eluted Covalently bound pyrroles might be removed, either by a reversal of the alkylation reaction or through breakdown of the tissue constituent Alternatively, the pyrrole function might be metabolically removed, leaving a smaller fragment attached to the tissue constituent, or it may react with an electrophilic group, as mentioned earlier Thus, because no colour reaction can be obtained in liver tissue after, say, 48 h, this does not necessarily mean that no fragment of the alkaloid molecule remains The Ehrlich reaction is an insensitive test for trace amounts, and final residues may in any case be Ehrlich-negative

Emphasis has been placed on pyrroles, because these can be detected easily Evidence connecting these with alkaloid hepatotoxicity, though strong, is, however, circumstantial the phenomena occur at the same time More work will be needed to further establish the connexion The possibility of other, undetected metabolites must not be overlooked

I thank Dr J. M Barnes for valuable discussions, Dr W H Butler for help with the pathology, Dr Francesco De Matteis for carrying out tests for naturally occurring pyrroles, Dr L Keefer, Mr James Loo and Dr W. Lijinsky (Chicago) for help with NMR and mass spectra, B A J Alexander and C R Kennedy for technical assistance, and B W Street for the liver fractionation

LETTERS TO THE EDITOR

PLANETARY SCIENCE

Occurrence of Olivine in a Type I Carbonaceous Meteorite

A REPORT of the discovery of olivine in the Orgueil carbonaceous meteorite[1] aroused considerable scepticism[2,3]. The identification was based on selected area electron diffraction patterns obtained from two mineral fragments observed during an electron microscope examination of a powdered meteorite specimen. Because, with the electron microscope in use at that time, it was only possible to examine particles in the orientation which they had arbitrarily taken up on the specimen support film, each diffraction pattern gave only limited information about the unit cell parameters and space group of any individual unknown mineral. The possibility of using such restricted data to identify mineral species rests on the fact that many minerals develop pronounced and specific faces, either by growth or cleavage, so that different fragments of the same mineral tend to lie in a common orientation, and thus to exhibit the same type of single crystal diffraction pattern in the electron microscope. The match between patterns from terrestrial olivine samples and those from olivine in Orgueil was good, but it was clearly desirable to put the identification on a firmer basis, if possible, by obtaining for a single mineral particle the full complement of unit cell parameters and the space group.

A Philips *EM*-300 electron microscope equipped with a goniometer stage made it possible to take diffraction patterns over a wide range of crystal orientations and thus to re-create virtually the entire reciprocal lattice of an unknown mineral. The Philips goniometer stage permits tilt through ±60° and rotation through 360°. The rotation axis coincides with the centre of the specimen

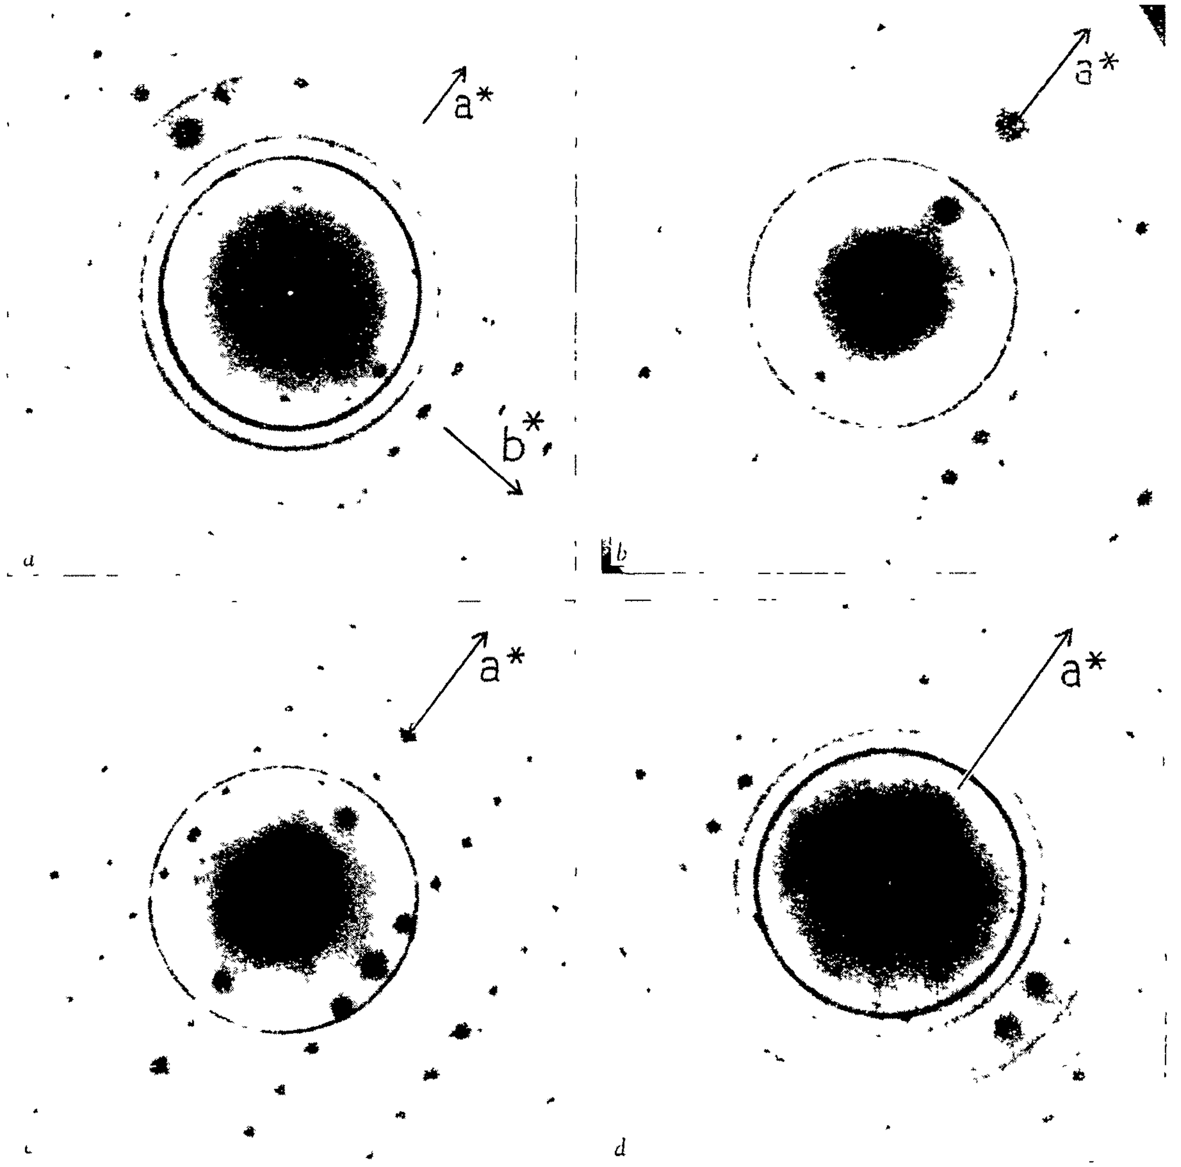

Fig 1. Selected area electron diffraction patterns taken at different orientations of an olivine crystal from the Orgueil meteorite. The tilt axis common to all four patterns coincides with the a^* axis of the reciprocal lattice. Angles of tilt relative to the normal specimen plane are *a*, −25°, *b*, 0°, *c*, +12°, and *d*, +23°. The innermost powder ring is the 2.338 Å reflexion of the aluminium standard.

grid, but an important advantage of this goniometer stage is that the tilt axis can be adjusted to intercept the electron optic axis for any position on the grid Thus the crystal remains stationary in the field of view during changes in tilt orientation, so that it is possible to observe the diffraction pattern directly in the microscope while the orientation is changing Both tilt and rotation are motor-driven. For this study, the anti-contamination device was in operation, for photographing patterns over a full range of orientations can result in the crystal being irradiated for up to 1 h during which considerable contamination, with consequent deterioration of the diffraction pattern, would occur The blades of the anti-contamination device restricted the range of tilt angles from ±60° to ±45° This was not, however, a real disadvantage, for, at the extreme angles of tilt, the path length for electrons through a crystal, which is commonly flattened in the direction perpendicular to the microscope grid, became so great that the beam was almost entirely absorbed

During a recent examination of a sample of the Orgueil meteorite a series of patterns was obtained from an irregularly shaped fragment approximately 2μ in diameter Four of these patterns are shown in Fig 1 The single crystal reflexions are produced by the unknown mineral and are superimposed on a powder pattern caused by the aluminium film used both to support the specimen and as a built-in diffraction standard for determining the scale of the unknown patterns By measuring the patterns it was possible to construct reciprocal lattice sections parallel to the electron beam All reflexions can be fitted to an orthorhombic network corresponding to a unit cell with parameters of 4 69 ± 0 10 Å, 6 04 ± 0 01 Å and 10 33 ± 0 03 Å. Following the conventions of Donnay[4] these are designated as the *c*, *a* and *b* axes, respectively.

The next stage in the identification is the elucidation of space group data from systematic absences among the reflexions These are listed in Table 1

Table 1 CONDITIONS FOR APPEARANCE OF REFLEXIONS

Reflexion	Condition	Conclusion
hkl	No conditions	Primitive cell
$hk0$	$k=2n$	*b*, Glide plane parallel to (001)
$h0l$	Not observed	
$0kl$	No conditions	
$h00$	$h=2n$*	Two-fold screw axis along <100>

* Reflexions, visible on some patterns, with $h \neq 2n$ are caused by double diffraction brought about by dynamical interactions

The possibility must be considered that the condition observed for $h00$ reflexions is a special manifestation of a more general condition and two such conditions are given in Table 2

Table 2 MORE GENERAL CONDITIONS WHICH COULD LEAD TO OBSERVED $h00$ CONDITION

Reflexion	Condition	Conclusion
$h0l$	$h=2n$	*a*, Glide plane parallel to (010)
$h0l$	$h+1=2n$	*n*, Glide plane parallel to (010)

Space groups which fulfil these observational requirements are $P2_1ab$, $P2_1nb$, $Pmab$ and $Pmnb$ The space group of olivine is $Pmnb$ The values of the unit cell parameters correspond to an olivine with 40–45 per cent fayalite which falls near the top of the olivine compositions observed in type II carbonaceous meteorites[5,6] It should be pointed out that olivine has never been observed as a contaminant in this laboratory

The significance of olivine in a type I carbonaceous meteorite is that it is necessary to postulate a high temperature (that is above about 500° C) stage for at least a small fraction of the meteorite and this seems to be incompatible with suggestions that such a meteorite is identical to primitive, unaltered cosmic material[7–9] It is concluded that type I meteorites resemble those of type II in that they are largely mechanical mixtures of minerals with different thermal histories[5,6,10]. This mixing must have occurred after the aqueous reaction stage necessary to explain certain other mineralogical features of the carbonaceous meteorites[1–3,11]

I thank Professor J D Bernal for advice and encouragement and Dr G F Claringbull for the specimen of Orgueil

Composition of the Optically Active Fraction of a Texas Petroleum

Hills and Whitehead have investigated the optically active components of Nigerian, Libyan, Kuwaitian and Iranian crude oils[1,2] The enriched optically active fractions from these sources have been found to contain pentacyclic triterpanes and, furthermore, they seem to be made up essentially of the same components, although in varying proportions We have found that these generalizations also seem to be true for the optically active material from a Texas petroleum

Louis[3,4] has isolated an optically active saturated solid hydrocarbon mixture (purest sample $\alpha_D = +36°$) from a

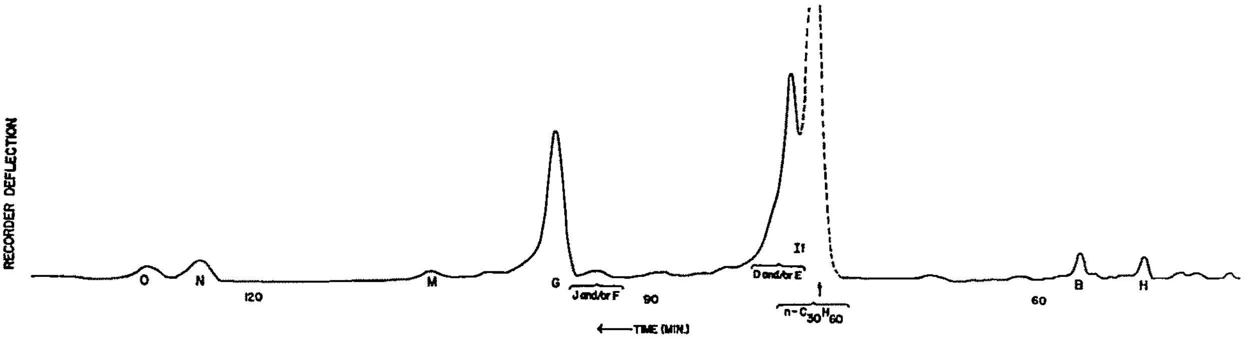

Fig 1 Part of a chromatogram of the optically active fraction isolated from the Mirando crude oil with added n-$C_{30}H_{62}$ 148 ft glass capillary of 0 01 in inner diameter, coated with *SE* 52 silicon gum Carrier gas hydrogen at 250° C Flame ionization detector Solvent peak (cyclohexane, not shown) appears at 2 min 11 s after injection

fraction (boiling range 162°–191° C at 0 01 mm) of the crude oil from Mirando A sample of this material was chromatographed on a capillary column in the same conditions as the optically active fraction originating from the Nigerian oil[1] (Fig 1, and ref 1, Fig 5), the stationary phase used was, however, *SE* 52 instead of *SE* 30 silicon gum

By co-injection of a mixture of the two optically active materials (on a glass column 148 ft × 0 01 in internal diameter, coated with *SE* 52, *t*, 250° C) it was shown that the Nigerian fraction caused peak enhancement of the chief components marked[1] *H*, *B*, *D* (and/or *E*, and possibly *I*), *J* (and/or *F*), *G*, *M*, *N* and *O* (Fig 1)

The mass spectra of the material, using ionization potentials of 15 and 70 eV, are given in Fig 2 Comparison of the peak intensities in the two conditions showed, notably, that the two most prominent ion masses, that is, 398 and 412 m/e, are molecular ions These peaks correspond to pentacyclic hydrocarbons of the formula $C_{29}H_{50}$ and $C_{30}H_{52}$, respectively It is further seen that the fragment at 191 m/e is of relatively high intensity particularly at 70 eV This fragment is considered to be characteristic of triterpanes[5] and is found, for example, in the following components of the Nigerian fraction[1] *E* and *F* (prominent masses at 413 and 191 m/e), and *D* (prominent masses at 398 and 191 m/e)

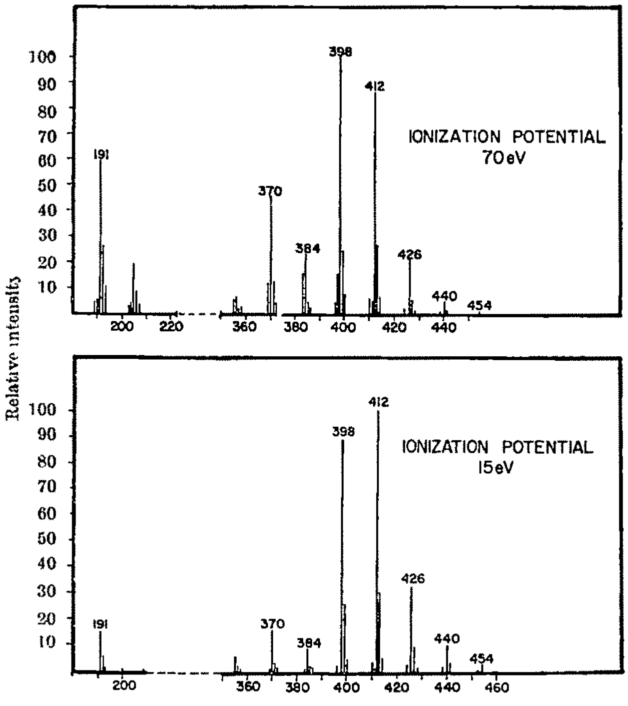

Fig 2 Mass spectra of the optically active fraction isolated from the Mirando crude oil, measured with an ionization potential of 15 and 70 eV, respectively

The large degree of coincidence of the gas chromatographic and mass-spectral data is also exhibited by the nuclear magnetic resonance spectra. The ratio of the methine plus methylene protons to the methyl protons has been found to be equal to about one for the Mirando sample

This evidence suggests that the optically active fractions from the Texas petroleum, and those from the African and Middle Eastern crude oils examined previously, may have, qualitatively, a largely similar composition The proportion of the various components seems, however, to vary In particular, *J* and *F* are found only in small amounts in the Mirando sample investigated Similar observations were made for the fractions originating from Libya and the Middle East, as compared with the Nigerian petroleum[1] It should, however, be remembered that the method of isolation used by Louis[3,4] differed from that of Hills and Whitehead[1]. Further work is needed to determine the extent to which the quantitative differences observed are analytically significant.

We thank E V Whitehead for carrying out the gas–liquid chromatographic analysis of our samples and for comparing the results with those reported in ref 1.

Composite Minor Intrusions in South Eastern Snowdonia

Composite minor intrusions were first recognized in North Wales by Beavon[1], who described a series of sills between 5 and 300 ft thick which are concordantly emplaced among lower Caradocian Glanrafon Slates outcropping on the eastern limb of the Arddu syncline (Fig 1) The sills have features which characterize them as composite minor intrusions as defined by Bailey and McCallien[2].

Mapping in the area to the north west of Blaenau Ffestiniog (Fig 1) has shown that the intrusions Beavon described are part of a more extensive suite which outcrop from the Glaslyn estuary to the neighbourhood of the Crimea Pass, between Blaenau Ffestiniog and Dolwyddelan They are emplaced among a great plexus of dolerite sheets which surround the mid-Caradocian volcanic ring structure of south-central Snowdonia[3,4]

The composite intrusions of the north eastern part of the area differ substantially from those described by Beavon and from most composite sheets of the British Tertiary province and elsewhere First, the basic margins of the sills vary in thickness between 0 and 150 ft even within a single intrusion, whereas the basic margins of the Tertiary composite intrusions are usually thin (2–6 ft) and remarkably constant even where there are local irregularities in the form of the intrusion[5]

Second, the acid components of the two largest sills leave their basic envelopes, by lateral failure of the basic margins in the case of the Allt Fawr sill and by transgression of the acid core of the Llyn Coch sill to form a dyke in the overlying rocks (Fig 1)

These intrusions afford a unique opportunity to examine the behaviour of the acid magma both within and outside its envelope of basic rocks Their basic margins are usually identical to the augite dolerites which are well documented throughout North Wales[6–9] The acid cores are made up from fine grained, equigranular granodiorite, or flow banded and spherulitic quartz latite which are both chemically and mineralogically similar to massive quartz latite intrusions which invade the Moelwyn Volcanic Series, about 1,000 ft stratigraphically below the composite sills[10] The acid member is not chilled against the dolerite, although the acid rocks contain sporadic xenocrysts of plagioclase like the feldspar in the basic margins The dolerite, however, often possesses a fine grained margin where it is in contact with the acid rock This marginal rock is riddled with secondary quartz, feldspars are highly decomposed and original pyroxene is converted to chlorite and acicular amphibole Its appearance suggests metamorphism by the acid member rather than chilling in the manner envisaged by Walker and Skelhorn[11] Lower contacts between the acid member and the dolerite are straight but thin and regularly spaced acid veins with matching contacts which penetrate downwards into the basic rock along incipient joints Small, subangular xenoliths of dolerite are aligned parallel with the contacts in the lower few feet of the acid member of the sills At upper internal contacts, the dolerite frequently lobes downwards into the acid core Sometimes the lobes are completely detached and form xenoliths with crenulate margins In the Llyn Coch sill flow, banding in the acid core sweeps upwards towards the dolerite roof from opposite directions, diverges and then runs parallel with the contact Where the flow bands sweep upwards and bifurcate, the dolerite sags into the negative area between them At the point of bifurcation the number of vesicles in the acid rock rapidly diminishes, suggesting that the discharge of volatiles at such points may have contributed to the upward flow of heat energy responsible for the local reomorphism of the overlying dolerite

Where the acid cores of the large Allt Fawr and Llyn Coch sills leave their basic envelopes, there are rapid changes in texture, grain size and in the style of contact metamorphism adjacent to the intrusions Where the core of the Allt Fawr sill lies within its dolerite envelope, it is made up from fine grained, equigranular granodiorite As the envelope thins, and finally disappears out, the acid core becomes finer grained and passes into flow banded and spherulitic quartz latite The Llyn Coch sill, emplaced at a higher stratigraphical level, has a core of flow banded quartz latite Where the acid member leaves its envelope and transgresses into the overlying sediments the rock becomes nodular The size and frequency of the nodules increase rapidly away from the dolerite envelope Blake *et al*[5] have suggested that in mixed acid/basic intrusions the presence of the basic magma increases the mobility of the acid magma They infer that the increased mobility is brought about by heat exchange between the hotter basic and the cooler acid magma The behaviour of the acid components in these composite sills supports this suggestion in that there was a marked increase in the viscosity of the acid magma where it left its warm dolerite envelope and where crystallization of the acid component was apparently more rapid A consideration of metamorphism adjacent to the composite intrusions suggests that the retention of volatiles also played an important part in increasing the mobility of the magma within the basic envelope Adjacent to the dolerite envelopes of the composite intrusions, metamorphism of the country rocks is similar to that associated with ordinary dolerite intrusions in the same area The shaly sediments are baked and have resisted cleavage Minutely spotted adinole is developed around the thick basic margins of the Llyn Coch sill and above the upper dolerite of the Allt Fawr sill Where the acid components of the sills leave their basic envelopes the style and extent of metamorphism change rapidly The sediments above the acid member of the Allt Fawr sill are heavily spotted with chloritic pseudomorphs after cordierite for 150 ft above the intrusion The style of metamorphism reflects only that component of the sills which is in contact with the country rocks The more extensive metamorphic aureole above the cooler acid

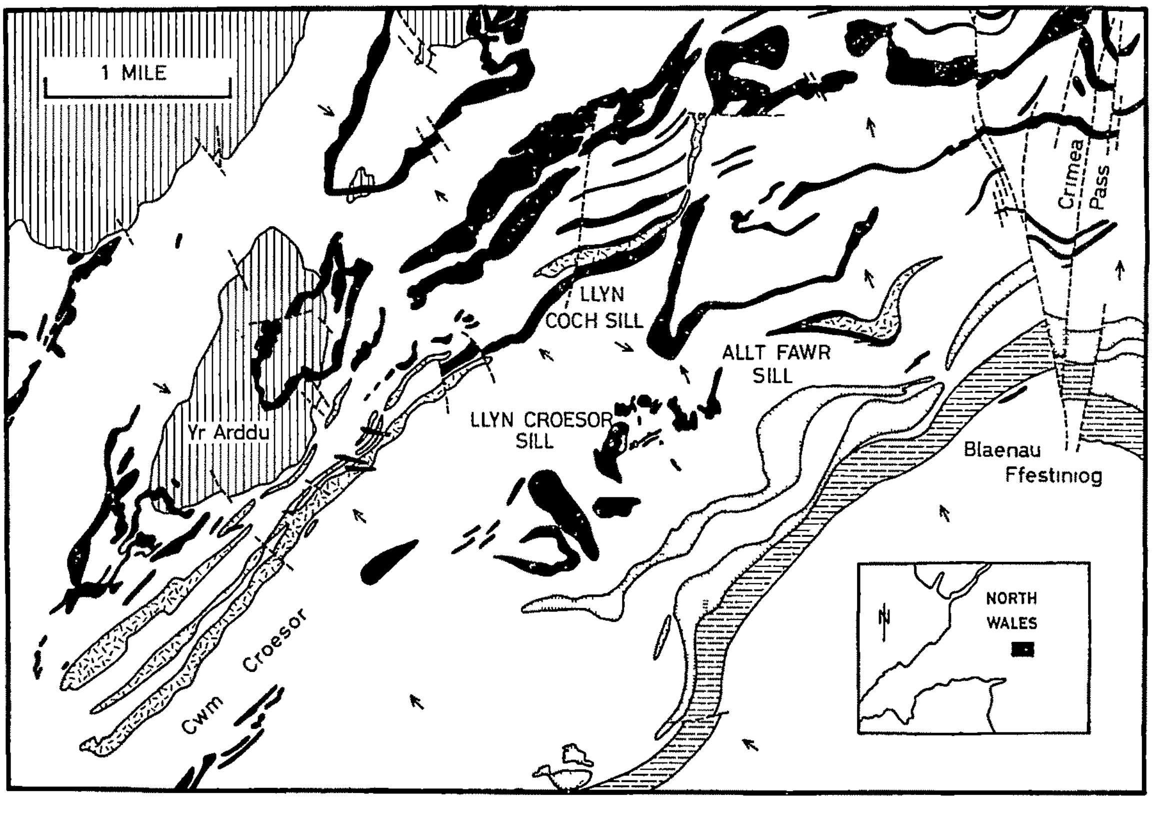

Fig 1 Simplified geological map to show the location of composite minor intrusions in south eastern Snowdonia Composite minor intrusions, dashes, dolerite, black, quartz latite, dots Cambrian, unornamented, Lower Ordovician, broken lines, Glanrafon Series, unornamented, Snowdon Volcanic Series, vertical lines Arrows indicate dip of bedding, faults, broken lines Inset map, location of area

member of the Allt Fawr sill suggests that volatile streaming into the surrounding sediments played an important part in metamorphism and that even a thin basic envelope prevented volatiles escaping from the acid member It seems likely that the retention of volatiles was important in maintaining higher mobility of the acid magma within its basic envelope

Blake *et al*[5] have suggested that in the formation of mixed acid/basic intrusions, acid magma mobilized at depth by rising basic magma rapidly prevents the continued rise of basic material Thus the basic margins of composite intrusions tend to be uniformally thin The unusual thickness of the basic margins of these intrusions can be explained by assuming that mobilization of the acid member took place more slowly so that correspondingly more basic material rose to a high level. There is some indication of a time lag between the arrival of basic and acid components in that incipient joints formed in the lower basic margins before the acid magma was emplaced The crenulate basic xenoliths in the upper parts of the acid cores of the sills can be shown to have been derived from the upper dolerite margins The occurrence of such xenoliths has been cited as evidence of the simultaneous liquidity of acid and basic magma[5,11] The contrasting behaviour of the dolerite at the upper and lower internal contacts in the Snowdonian intrusions suggests that the basic magma had become sufficiently viscous to fracture before the acid magma arrived Upward flow of heat energy and probably discharge of volatiles at the acid/basic interface caused partial reomorphism of the dolerite, giving rise to lobe structures and in extreme cases to detached xenoliths within the acid hosts

The composite sills of south eastern Snowdonia demonstrate conclusively that acid and basic magmas existed simultaneously in the Caradocian volcanic province of North Wales The basic component of the sills is identical in every way to the dolerites with which they are spatially associated This suite of dolerites has been interpreted as belonging to the mid-Caradocian (Snowdon Volcanic Series) igneous cycle[3,4], and it seems likely that the composite minor intrusions belong to the same phase of activity The acid cores of the intrusions, however, have much closer affinities with the sodic quartz latite intrusions associated with the lower Caradocian Moelwyn Volcanic Series than with the dominantly potassic rocks of the Snowdon Volcanic Series What is more significant is that the composite intrusions have much the same lateral extent as the quartz latites which outcrop about 1,000 ft below them It is possible that basic magma, rising through the already emplaced quartz latite sills, remelted portions of them and that the reconstituted acid magma rose to higher levels and was emplaced among the dolerites Elsewhere, away from the quartz latite sills, the basic magma was emplaced as a suite of simple dolerites

PHYSICS

Radial Distribution Functions from Small Packings of Spheres

Scott[1] has derived a radial distribution function from a packing of about 1,000 spheres by measuring the Cartesian co-ordinates of each sphere and calculating the individual distribution functions of each of a group of 25 spheres known to be in the centre of the packing These 25 separate distribution functions were averaged to give the final result Clearly the edge of the packing interferes and limits both the maximum radial distance to which the distribution function can be determined and the number of centres that can be found sufficiently far from this edge An improvement would be to use all the spheres in the packing as centres and to correct the distribution function obtained for the effect of the edge A maximum separation equal to the diameter of the packing would be obtainable together with better statistics in the histogram Alternatively, results similar to those of Scott[1] could be obtained from packings of half the linear size containing only about 125 spheres.

If it is assumed that the packing is spherical in shape, with radius $R_{\max}$, that it is homogeneous and of density ρ_0 centres per unit volume, and if the radial distance of the distribution function is r, then all spheres within a distance of $(R_{\max} - r)$ from the centre of the packing will have complete shells of neighbours within the radius r and so no correction need be applied. The spheres between $(R_{\max} - r)$ and $R_{\max}$ are the ones that do not have complete shells of radius r and a correction factor (F) has to be applied for these This factor will be the ratio of the number of pairs that should be observed to the number that actually are observed and will be a function of $(r/R_{\max})$ given values of r and $R_{\max}$

For an infinite packing the number of sphere centres in an elemental shell between r and $(r + \delta r)$ from a central sphere is

$$4\pi r^2 \rho(r) \delta r$$

where $\rho(r)$ is the radial distribution function For a centre at a distance R from the centre of a packing of limited size the apparent value of $\rho(r)$ will be less than the true

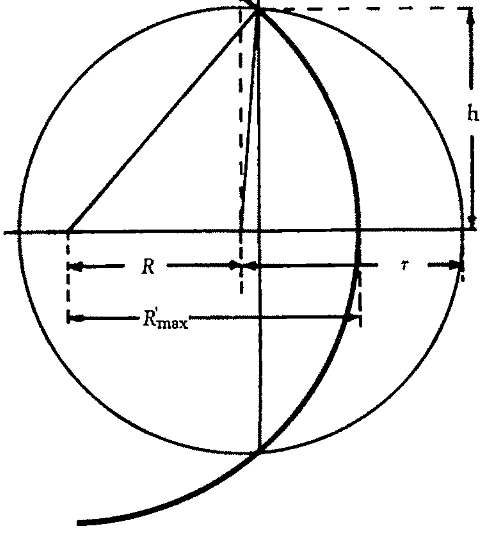

Fig 1 A section through a spherical packing of radius $R_{\max}$ The centre at a distance R from the packing centre only has a partial shell of neighbours at a distance r

value because part of the shell will lie outside the packing (Fig 1) The fraction will be the ratio of the area of the cap of the sphere, radius r, inside sphere radius $R_{\max}$, to the total area of the sphere radius r Thus the apparent density from the centre at R is

$$\rho_{A,R}(r) = \rho(r) \quad \frac{(r+x)}{2r}$$

where

$$x = \frac{R_{\max}^2 - R^2 - r^2}{2R}$$

The number of centres in an elemental shell, thickness δR and at a distance R from the centre of the packing to which $\rho_{A,R}(r)$ pertains, is

$$4\pi R^2 \, \delta R \, \rho_0$$

Thus the apparent density $\rho_A(r)$ taken over the whole packing will be

$$\rho_A(r) = \int_0^{R_{\max}} \frac{(\text{number of centres}) \, \rho_{A,R}(r)}{\text{total number of centres}}$$

$$= \frac{\int_0^{(R_{\max}-r)} 4\pi R^2 \, \rho_0 \rho(r) \, \mathrm{d}R + \int_{(R_{\max}-r)}^{R_{\max}} 4\pi R^2 \, \rho_0 \rho(r) \, \frac{(r+x)}{2r} \, \mathrm{d}R}{\int_0^{R_{\max}} 4\pi R^2 \, \rho_0 \, \mathrm{d}R}$$

Because $\rho_A(r)$ is the apparent density observed for the packing of limited size, the correction factor (F) by which the experimental density has to be multiplied to give the true distribution function is

$$F = \frac{\rho(r)}{\rho_A(r)}$$

Integrating $\rho_A(r)$ and substituting $y = \left(\frac{r}{R_{\max}}\right)$ gives

$$F = \frac{16}{(y-2)^2(y+4)}$$

When $r \geqslant R_{\max}$, there can be no core of centres in the packing with a complete shell of neighbours Consequently a term is lost in $\rho_A(r)$ which becomes

$$\rho_A(r) = \frac{\int_{(r-R_{\max})}^{R_{\max}} 4\pi R^2 \, \rho_0 \rho(r) \, \frac{(r+x)}{2r} \, \mathrm{d}R}{\int_0^{R_{\max}} 4\pi R^2 \, \rho_0 \, \mathrm{d}R}$$

and

$$x = \frac{R^2 + r^2 - R_{\max}^2}{2R}$$

Integration gives the same correction factor as before

$$F = \frac{16}{(y-2)^2(y+4)}$$

When $y = 0$ there is no edge effect and $F = 1$ When $y = 1$, $F = 3\ 2$ When $y = 2$ the pair separation equals the diameter of the packing and $F = \infty$.

The co-ordinates of Scott[1], corrected by Bernal and with a few additional minor corrections, were analysed in this way The packing density was calculated for spherical samples of increasing radius cut from the packing (Fig. 2) The actual volume of solids within this radius was determined by calculating the volume of the spheres totally within the radius and adding the inner sphere segments of those spheres intersecting the radius The edge of the packing was determined by the radial distance at which this packing density began to decrease rapidly

A spherical sample, radius 15 0 mm and containing 536 spheres, was taken from the packing and the separation of every pair of spheres determined The uncorrected radial distribution function was determined for intervals of 0 05 sphere diameters. The correction factor was then evaluated and applied for each of these intervals and the result reduced to the average value for one sphere by division by 268 and normalized by division by $4\pi r^2 \delta r$ where r was the radial distance and δr the interval width in diameters (0 05 in this case).

The results are shown in Fig 3 and they reinforce the observations of Scott[1]. The structure of the peaks can, however, be more clearly seen. The peak at 1 0 diameters is very sharp as would be expected for hard spheres but the peak between 1 7 and 2 0 is curiously square The other peaks slowly merge into the continuum at about 5 5 diameters

Fig. 4 shows the structure in the important region between 1 and 1 5 diameters The number of neighbours within a radial distance is plotted against distance At 1·1 diameters this is in agreement with Scott[1], who found 9 3 ± 0 8 neighbours There are, however, only about 5 actual contacts but the gradient is very steep in this

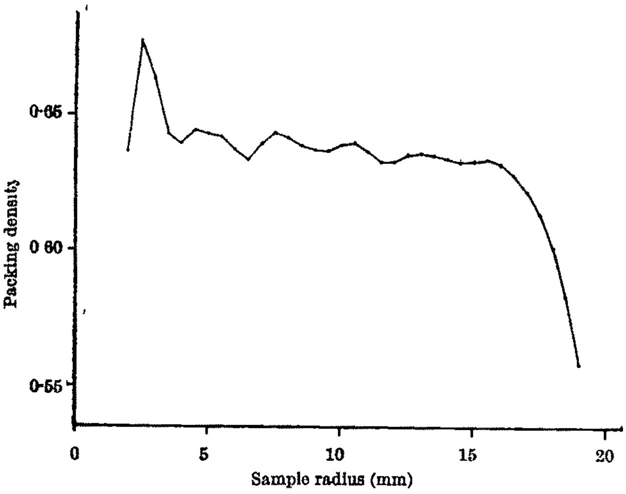

Fig 2 The packing density of spherical samples of increasing radius cut from the packing

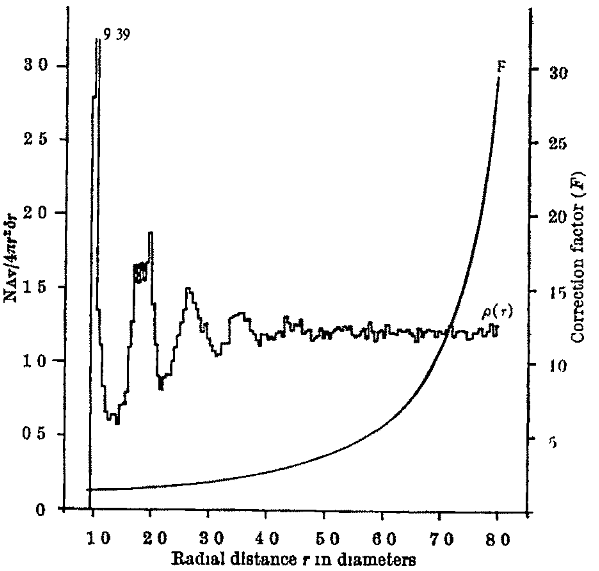

Fig 3 The radial distribution function, ρ(r), showing also the values of the correction function (F)

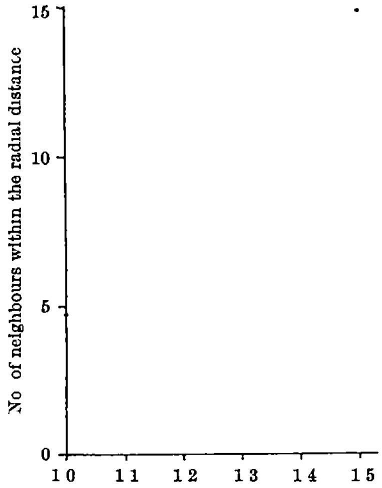

Fig 4 The cumulative near neighbour distribution function The average number of neighbours within a radial distance (r) of the central sphere is shown

region and there are nearly 7 neighbours within 1 02 diameters

I thank Mr and Mrs A C Wright for their helpful discussions. I also thank Professor G D Scott for a copy of the original co-ordinates of his packing and Professor J D Bernal for the few corrections to these co-ordinates

Rational Geometry for measuring Elastic and Viscoelastic Parameters

Recent developments in rubber elasticity theory have led to the recognition that measurements of elastic properties of gels and rubbers near the gel point are of special value[1-3] The need to develop new methods of measurement has been foreshadowed[2]. We describe here a method under trial for materials in the range 10^3–10^5 dyne cm^{-2} (but which could be extended well beyond this range), the importance of which stems from its rational basis

Elasticity investigations depend on measuring deformation in response to an applied force The geometry of the area over which the force is applied to the specimen is important, for it will enter the interpretation of experimental data through the boundary conditions for the differential equations which are relevant. Even in the domain of routine uniaxial tensile modulus measurements, international committees have given much thought to the best geometry of the clamps which transmit the force (see ref 4)

From both the experimental and theoretical viewpoints, perhaps the simplest testing geometry is that of a rigid sphere embedded in a large reservoir of the material under examination For materials which adhere to the spherical surface, it is possible to obtain complete theoretical solutions for the relation between the displacement of the sphere ξ and the externally applied force F. Under static conditions the relation for an incompressible material is

$$F = 6\pi\mu a\xi \qquad (1)$$

where μ is the shear modulus and a the radius of the sphere. Thus for materials which exhibit the appropriate tactile properties, measurement of F and ξ leads directly to a value of μ

Preliminary results for a nickel sphere (radius $a = 0\ 0080$ cm) embedded in a gelatine gel are shown in Fig. 1 The sphere was at distance $> 50a$ from the surface of the gel An electromagnet capable of generating up to 1,000 gauss at the sphere was used to exert forces of order 1 dyne on the sphere These forces were calibrated in terms of the "pick-up distance" of the free nickel sphere versus its distance from the tip of the electromagnet (At the pick-up distance the magnetic force just exceeds the known weight of the sphere) Displacements of the embedded sphere were measured with a microscope (magnification × 400), they were reproducible for several hours and reversible within experimental error Fig 1 shows linear elastic behaviour up to the maximum displacement of about 0 7a Young's modulus calculated from the slope is $1\ 30 \times 10^4$ dyne/cm^2 (using equation (1) and assuming Poisson's ratio to be 1/2) As a check, a value of $2\ 1 \times 10^4$ was obtained on a sample of the same gel by the surface indentation method[5] The agreement is thought to be satisfactory because the surface method is much less accurate and liable to give high values of Young's modulus owing to loss of plasticizing action by evaporation of water

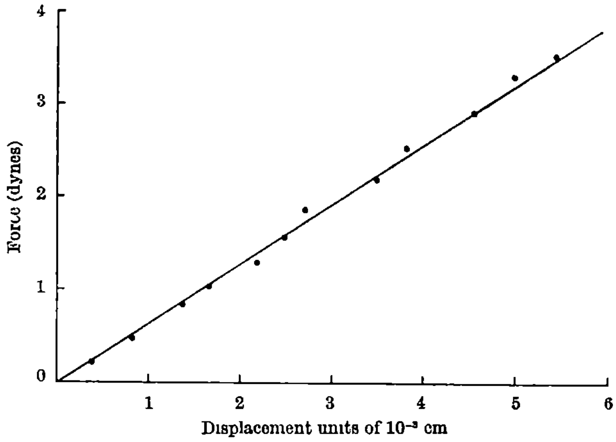

Fig 1

One of us[6] has generalized the result (1) to the case of time dependent displacement $\xi(t)$ The principal result is that for an elastic solid, (1) is replaced by

$$F = 6\pi\mu a\xi + 6\pi a^2(\mu\rho)^{1/2}\dot{\xi} - \tfrac{1}{2}M\ddot{\xi} \qquad (2)$$

where ρ is the density and $M = 4\pi a^3\rho/3$ is the mass of material displaced by the sphere. In turn, equation (2) is readily generalized to the viscoelastic case[6], thus permitting analysis of dynamic experiments in terms of viscoelastic parameters

One of us (J A L) thanks the Plastics Institute education fund for a grant

Tensile Strength of Granular Materials

In several communications[1-4] on the tensile strength of granular materials bound by liquids, authors have tried to confirm or improve the equation of Rumpf[5]. At the Institute of Mechanical Process Engineering of the University of Karlsruhe, where the first measurements of the tensile strength of moist agglomerates started in 1957, investigations have recently led to a complete theoretical and experimental description of the tensile strength relationship in the whole moisture range.

Considering previous communications, it should first be pointed out that the liquid in moist or "green" agglomerates can be distributed in three characteristic ways, which depend on the amount of liquid present and the porosity of the agglomerate. These are (*a*) the "pendular state" with only liquid bridges between the individual particles which make up the agglomerate; (*b*) the "capillary state" in which all pores within the pellet are filled completely with the liquid which forms concave menisci at the pore ends, and (*c*) a transition range where both liquid bridges and capillaries filled with liquid are present. The binding mechanisms are different for all three ranges.

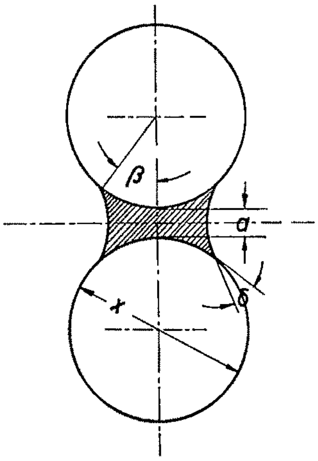

Fig 1 Liquid bridge between two spherical particles of equal size (model)

Theoretically, equations for the cases (*a*) and (*b*) can be derived. Equation (1) is the relationship derived statistically by Rumpf[5]

$$\sigma_{tg} = \frac{9}{8} \cdot \frac{1-\varepsilon}{\varepsilon} \cdot \frac{H(x)}{x^2} \tag{1a}$$

where σ_{tg} is the tensile strength of granular materials which is produced by binding forces, $H(x)$, of any physical nature at the co-ordination points between the individual particles within the agglomerates, ε is the porosity of the pellet and x is the mean size of the particles forming the agglomerate. For a liquid bridge between two special particles of equal size x with a distance a at the co-ordination point (Fig 1), the binding force is[6]

$$H(x) = \alpha \quad x \quad FH$$

where α is the surface tension and $FH = FH(\beta, \delta, a/x)$ is the complicated function of the half centriangle β, the contact angle δ and the dimensionless length ratio a/x. Thus σ_{tb}, the tensile strength of agglomerates in the bridge or "pendular" state, is

$$\sigma_{tb} = \frac{9}{8} \; \frac{1-\varepsilon}{\varepsilon} \; \frac{\alpha}{x} \; FH \tag{1b}$$

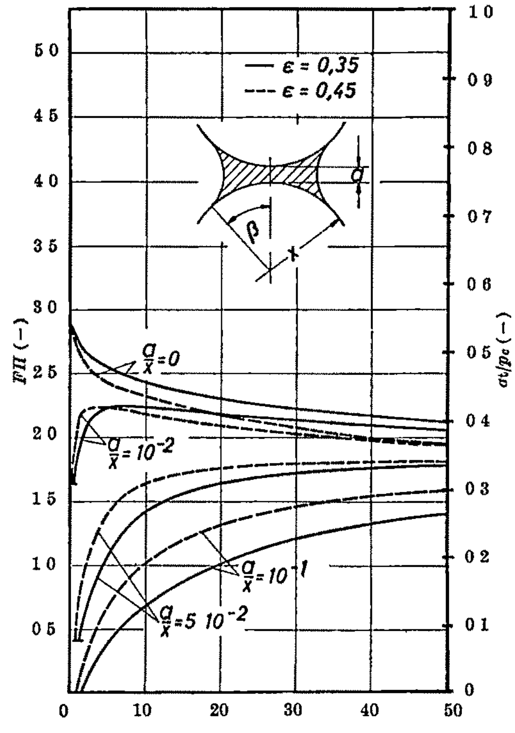

Fig 2 Dimensionless adhesion force, *FH*, as a function of the percentage liquid saturation, *S*. Parameters are the length ratio, *a/x*, and the porosity, *ε*

Fig 2 shows the dimensionless adhesion force, *FH*, plotted against the percentage saturation, *S*, the relation between the pore volume occupied by the liquid and the total pore volume of the pellet[6]. Different porosities, ε, and distances, a, give different curves. Because in practice no absolutely smooth particles are found, the case $a = 0$ seldom occurs in a real agglomerate. In most cases, the situation at the co-ordination points is very probably similar to that shown in Fig 3. This explains the discrepancy between the Haines–Fisher equation, which was derived assuming $a = 0$ and experimental results[4]. Recent measurements of tensile strengths of granular materials in the "pendular state" are in good agreement with the theoretical curves shown in Fig 2, if an experimentally estimated length ratio, a/x, is introduced (result to be published).

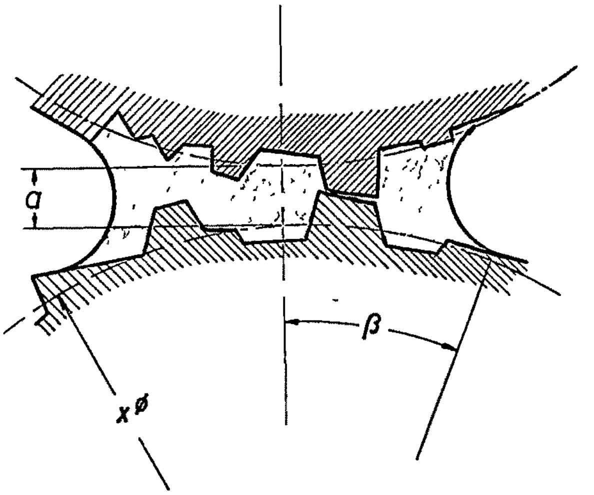

Fig. 3 Schematic representation of a liquid bridge at the co-ordination point of two real particles

Equation (2) is the relationship for the capillary pressure in granular materials, because the tensile strength of agglomerates in the "capillary state", σ_{tc}, is approximately equal to the capillary pressure[5] According to Rumpf[5] a conventional equation for the capillary pressure, p_c, in granular materials is

$$\sigma_{tc} \sim p_c = \text{const} \; \frac{\alpha}{x} \; \frac{1-\varepsilon}{\varepsilon} \; f(\delta) \qquad (2a)$$

where $f(\delta)$ is a contact angle function which is, by definition, unity for liquids wetting the solid completely ($\delta = 0°$) The constant has values between 6 and 8.

Using certain assumptions, the capillary pressure in a liquid bridge between two spherical particles of equal size can also be used to characterize the capillary pressure in granular materials (result to be published) This equation reads

$$\sigma_{tc} \sim p_{cb} = \frac{\alpha}{x} \; FPC \qquad (2b)$$

where $FPC = FPC(\beta, \delta, a/x)$ is a complicated function of the half centriangle, β, the contact angle, δ, and the dimensionless length ratio, a/x (ref 6).

The tensile strength of moist granular materials can be described in the complete moisture range by assuming that the relationship between the tensile strength, σ_t, and the percentage liquid saturation, S, in the transition range (c) increases linearly from a point S^*—the critical percentage liquid saturation where liquid bridges in the aggregate begin to touch each other—to $S = 100$ per cent Below S^* the tensile strength is described by equation (1a)

Defining a tensile strength characteristic, FZ,

$$FZ = \sigma_t \; \frac{x}{\alpha} \qquad (3)$$

and a capillary pressure characteristic, FPK,

$$FPK = p_c \cdot \frac{x}{\alpha} \qquad (4)$$

the set of equations for the tensile strength of moist granular materials gives

$$FZ = \frac{9}{8} \; \frac{1-\varepsilon}{\varepsilon} \; FH = FZ_b \qquad \text{for } 0 \leq S < S^* \qquad (5a)$$

$$FZ = FZ_b^* + \frac{S - S^*}{1 - S^*} (FPK - FZ_b^*) \text{ for } S^* < S < 100 \quad (5b)$$

with

$$FZ = \frac{9}{8} \; \frac{1-\varepsilon}{\varepsilon} \; FH(\beta^*, \quad) = FZ_b^* \text{ for } S = S^* \qquad (5c)$$

and

$$FZ = FPK \qquad \text{for } S = 100 \qquad (5d)$$

Equations (5) represent, under the assumptions made previously, the most general solution of the problem The characteristics, FZ and FPK, can incorporate any equation for the tensile strength, σ_t, and the capillary pressure, p_c Fig 4 shows, for example, some tensile strength curves which were calculated using equations (1b), (2a) and (2b) and plotted in a dimensionless form over the percentage liquid saturation, S While below the critical percentage liquid saturation, S^*, the curves are unequivocal for a given set of ε and a/x values, they differ considerably in the transition range The dashed lines in Fig 4 represent the curves calculated according to equation (2a), where

$$FPK = \text{const} \; \frac{1-\varepsilon}{\varepsilon} \cdot f(\delta), \; \text{const} = 6 \text{ and } f(\delta) = 1$$

and the full lines have been calculated using equation (2b), with

$$FPK = FPC, \; \beta = 28° \text{ and } \delta = 0°$$

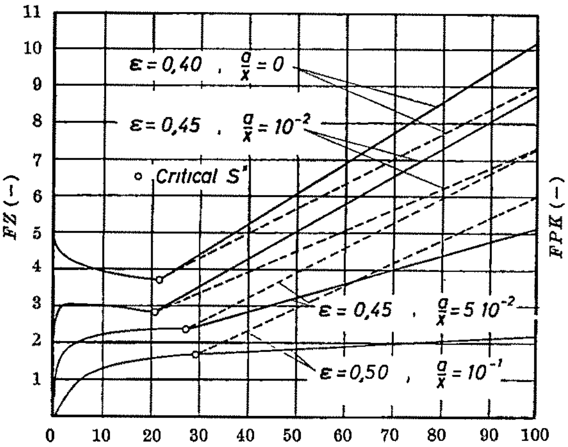

Fig 4 Theoretical tensile strength curves of moist granular materials Parameters are the length ratio, a/x, and the porosity, ε Both equation (2a) (– – – –) and equation (2b) (——) have been used for the calculation of FPK

The critical percentage liquid saturation has been estimated using the rules of spherical trigonometry

Experimental results confirmed the trend of the curves in Fig 4 Above the critical percentage liquid saturation a better approximation could be obtained by using equation (2b) (solid lines in Fig 4)

This research was made possible through the Deutsche Forschungsgemeinschaft, Bad Godesberg, West Germany The measurements of tensile strength were carried out in the Institute of Mechanical Process Engineering of the University of Karlsruhe by Mr E Hoffmann

THE SOLID STATE

Crystal Structures of some Protactinium Bromides

THERE has recently been considerable interest in the crystal chemistry of the f-electron transition elements The often unusual co-ordination arrangements found around these rather large metal atoms may in some cases be connected with f-orbital participation in the bonding Protactinium is of particular interest because of the proximity of the 5f and 6d energy levels, but few detailed structural studies of protactinium compounds have yet been reported

We briefly report here the results of three crystal structure determinations in which protactinium has been found to show co-ordination numbers of six, seven and eight Co-ordination numbers nine[1] and ten[2] for this element are also known

Protactinium pentabromide has been found to be dimorphic, and the crystal structure of one form—designated β—has been determined Work is proceeding on the α-form β-$PaBr_5$, obtained by sublimation at 400°–410° C *in vacuo*, crystallizes in the monoclinic system (unit cell $a = 8\ 385$ Å, $b = 11{\cdot}205$ Å, $c = 8\ 950$ Å, $\beta = 91{\cdot}1°$; space group $P2_1/n$) and is virtually isostructural

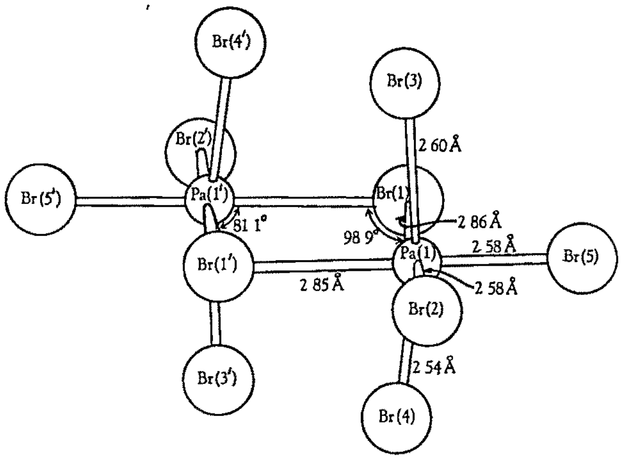

Fig 1 The dimeric Pa_2Br_{10} unit

with uranium pentachloride[3]. The bromine bridge is symmetrical, however, whereas UCl_5 has an asymmetric chlorine bridge. The *bis*-octahedral molecular unit (Fig 1) is obviously closely related to that of niobium (and tantalum) pentachloride[4] The structure has been refined by three-dimensional least-squares methods to a final residual of 9·05 per cent for 281 visually estimated single crystal reflexions The single-bond covalent radius of protactinium (V) derived from this six co-ordinate β-$PaBr_5$ structure is 1·44 ± 0·02 Å, which can be compared with the mean single bond values of 1·45 ± 0·02 and 1·52 ± 0·02 Å for the seven co-ordinate pentachloride, $PaCl_5$, and nine co-ordinate heptafluorocomplex, K_2PaF_7, respectively

Protactinium (V) oxytribromide also crystallizes in the monoclinic system (unit cell $a = 16{\cdot}911$, $b = 3{\cdot}871$, $c = 9{\cdot}334$ Å, $\beta = 113{\cdot}67°$, space group $C2$) The presence of static disorder in the best crystal available has complicated the structure determination, but due allowance for 22 per cent disorder in a full-matrix least squares refinement scheme has enabled us to attain a final residual of 11·8 per cent for 259 observed reflexions. $PaOBr_3$ has a double chain structure (Fig 2) in which each protactinium atom is seven co-ordinate The chains are bound together by oxygen and bromine bridging, each oxygen being co-ordinated to three protactinium atoms. The protactinium co-ordination sphere is a distorted pentagonal bipyramid and tends towards the C_2 arrangement of Claxton and Benson[7] A similar chain structure has been reported[8] for the non-stoichiometric uranyl complex $Cs_{0{\cdot}9}UO_3Cl_{0{\cdot}9}$ The $PaOBr_3$ structure is markedly different from that of $NbOCl_3$ (ref. 9) in which Nb—O—Nb—O chains are cross-linked by bridging chlorine atoms Full structural information is not available for either $NbOBr_3$ or $TaOBr_3$, but recent[10] infrared results suggest that the former has a similar type of oxygen bridge to that found for $NbOCl_3$, this niobium-oxygen stretching vibration occurs at 775 cm^{-1} in $NbOBr_3$ compared with 770 cm^{-1} for $NbOCl_3$ The protactinium-oxygen stretching vibrations, on the other hand, are observed at 515m, 476w, 364s and 303w cm^{-1}, and these lower values are presumably a consequence of the increased co-ordination number of the oxygen atoms

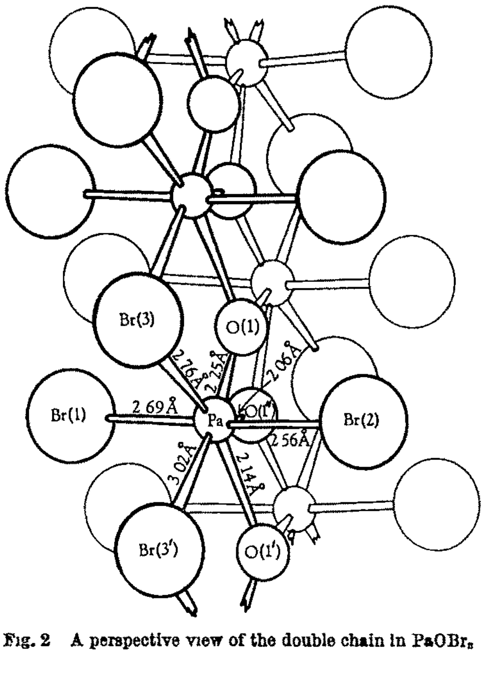

Fig. 2 A perspective view of the double chain in $PaOBr_3$

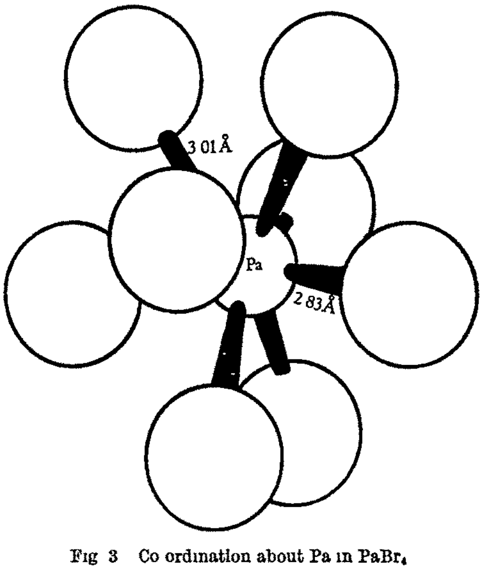

Fig 3 Co ordination about Pa in $PaBr_4$

Protactinium tetrabromide has been shown to be isostructural with thorium tetrachloride[11] It crystallizes in the tetragonal system (unit cell $a = 8{\cdot}824$ Å, $c = 7{\cdot}957$ Å, space group $I4_1/amd$). Intensity data were collected by the powder diffraction method, but because of difficulties of absorption correction, refinement has so far proceeded only to $R = 20$ per cent for forty-four observed reflexions The structure (Fig 3) is, however, confirmed and positional parameters are adequately determined The protactinium (IV) is co-ordinated by eight bromines in the form of a dodecahedron

Full experimental details of all three analyses will be submitted for publication in due course.

Contact Angles for Thin Lipid Films and the Determination of London–van der Waals Forces

From the theory of thin liquid films it is evident that the tension of the two-sided film should be less than twice the tension of the bulk liquid surfaces with which the film is in equilibrium. One would therefore expect there to be a contact angle between the thin film and the surfaces of the adjacent bulk liquid. This was recently pointed out by Mysels, Huisman and Razouk, who have also confirmed the existence and measured the magnitude of this contact angle for "black" aqueous soap films in air[1].

We now report some measurements of the contact angle between optically black hydrocarbon films in aqueous solution and the equilibrium bulk hydrocarbon liquid. The formation of films of this type has already been described[2,3], as have been the measurement of the film thickness and composition[4–9]. The contact angle in hydrocarbon/water systems is not readily measurable by the method of Mysels *et al.*, and we have used an interference method instead. The films were formed in a 1 mm hole in a horizontal block of 'Fluon' by an injection method similar to that of Vreeman (personal communication). When the formation of the black film was complete, vertical illumination by monochromatic light produced Newton's rings in the meniscus immediately adjacent to the edges of the black film. It is possible, in principle, to deduce the contact angle from measurements of the spacing of these rings. Indeed, Sheludko[10] has recently mentioned this approach and has referred to some unpublished results. This procedure, however, involves a difficult extrapolation and the following procedure was found to be an improvement.

The thinning of the film was controlled in such a way that when the formation of the black film was complete, a lens of bulk liquid remained as an island in the black film. Under monochromatic light, such a lens appears as shown in Fig. 1. This particular lens was 83μ in diameter but a wide range of sizes may be obtained. The lenses are evidently in equilibrium with the surrounding black film and remain constant in size and appearance for at least 30 min, by which time they have usually drifted to the edge and coalesced with the meniscus. Apart from the very small influence of gravity, we should expect the lenses to be symmetrical about a horizontal plane through the centre of the film and to consist of two spherical segments. Calculations from the orders and radii of the interference rings show that this is very accurately so. From the radius of the lens one can calculate the contact angle. From measurements of a number of lenses, no significant dependence of contact angle on the size of the lens was found.

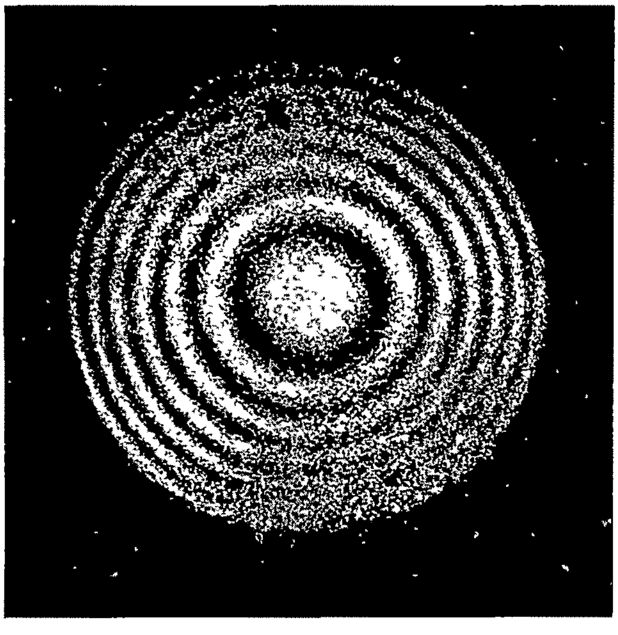

Fig. 1. A lens of diameter 83μ in an optically black lipid film as seen under vertically reflected monochromatic light

For films formed from a solution of pure glycerol mono-oleate in *n*-decane, the contact angle in an aqueous phase of distilled water for several lenses was calculated to be 1° 52′. The interfacial tension of the bulk media at 20° C was 3.72 dyne/cm so that the difference ($\Delta\gamma$) between this and one half of the film tension was 0.00197 dyne/cm.

A knowledge of this interfacial tension difference is important for at least two reasons. First, it enables the film tension to be determined from the bulk interface tension without having to bulge the film—a procedure which is often impossible owing to the breakage of the film[9,11]. Knowing the film tension, we can then apply the Gibbs equation to the determination of adsorption in the thin film[9,12]. Second, the interfacial tension difference for hydrocarbon films has an especially close relationship to the London–van der Waals forces for hydrocarbon/water systems. To a very close approximation, the free energy change on formation of 1 cm² of equilibrium thin film from thick film is, in the present systems, numerically equal to twice the difference in interfacial tension between the thin and thick film—in other words, to 2(−0.00197) or −0.00394 ergs/cm². This free energy change is made up of terms arising from the London–van der Waals, electrostatic (double layer), and steric forces acting in the film. The electrostatic term can be calculated to an order of magnitude from conductivity data together with an assumption of the value of the double layer potential and seems to be negligible. The steric forces are responsible for stabilizing the films, and the available evidence suggests that these arise from the steric interference of the alkyl chains of the surface active molecules (the glycerol mono-oleate in this case)[6]. These forces are evidently negligible until the opposing chains of the two monolayers meet each other, and then increase very rapidly with further decrease in film thickness. This point can be argued from theoretical considerations and from the fact that the thickness of the hydrocarbon part of the equilibrium film is very close to twice the length of the extended oleate chains[6]. By contrast, the London–van der Waals potential energy is, in the present systems, believed to be a much weaker function of the film thickness. The depth of the free energy minimum (ΔF) for 1 cm² of thin film (relative to that for a film of large thickness) should consequently be determined almost entirely by the London–van der Waals forces. We may therefore write[13]

$$\Delta F \simeq 2\Delta\gamma \simeq -\frac{A}{12\pi\delta^2} \times \text{retardation correction}$$

where A is the Hamaker–London–van der Waals constant and δ is the film thickness. For the present films, the thickness of the hydrocarbon core has been given as 47 Å (ref. 6) and the combined thickness of the polar group layers is estimated from models as approximately 8–10 Å. If we take δ as 56 Å and estimate the retardation correction from the data of Overbeek[14], we find that $A = 5.6 \times 10^{-14}$ erg.

From the nature of the assumptions involved, this value should be considerably more precise than previously published values for liquids. A more thorough appreciation of the validity of the assumptions is, however, needed, and this should be gained by the examination of further systems. It is interesting to compare this value with those obtained from flocculation data for lipid/water systems which depend on the validity of an electrical double layer model Thus for their arachidic acid sols Ottewill and Wilkins[15] found a value of the order of 10^{-14} erg and for aqueous suspensions of solid and liquid paraffinic hydrocarbon Srivastava and Haydon[16,17] found approximately 10^{-13} erg

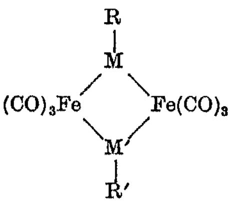
CHEMISTRY

Ligands containing Fluoroaromatic Groups

THE relatively high electronegativity of the pentafluorophenyl group, C_6F_5, is expected to alter the donor characteristics of ligand molecules We wish to report initial results of studies with three types of fluoroaromatic ligands

Pentafluorophenyl cyanide, C_6F_5CN, reacts partially with tungsten hexacarbonyl in petrol ether solvent, when the mixture is irradiated with ultraviolet light Two yellow compounds were separated by column chromatography under a nitrogen atmosphere, but in neither case could analytical samples be obtained, because all attempts at crystallization (under nitrogen) failed because of a facile decomposition The infrared spectra (in the region close to 2,000 cm^{-1}) of the solutions from the column were almost identical to those of $RCNW(CO)_5$ and $(RCN)_2W(CO)_4$ (R, alkyl) Clearly the pentafluorophenyl group is strongly affecting the stability of these complexes *bis*(Pentafluorophenyl)sulphide and -selenide do not react with either chromium hexacarbonyl or triiron dodecacarbonyl when heated under reflux in 80/100 petrol ether, and palladium dichloride forms no complex with pentafluorophenyl cyanide after 5 days at 110° C in a sealed tube

Iron pentacarbonyl and triiron dodecacarbonyl react with $S_2(C_6F_5)_2$, $Se_2(C_6F_5)_2$ (ref 1), $Te_2(C_6F_5)_2$* and C_6F_5SH to give air-stable compounds of the type



(I) M, M′=S, R, R′=C_6H_5
(II) M, M′=S, R=C_6F_5, R′=C_6H_5
(III) M, M′=S, R, R′=C_6F_5 (ref 2)
(IV) M, M′=Se, R, R′=C_6F_5
(V) M=S, M′=Se, R, R′=C_6F_5
(VI) M, M′=Te, R, R′=C_6F_5

^{19}F and ^1H nuclear magnetic resonance spectra of these dimers indicate the presence of isomers, but we have, so far, been unable to separate them by chromatographic techniques A comparison of the stabilities of I and III indicated little difference between them A competitive reaction carried out using triiron dodecacarbonyl (1 mole) and a mixture of $S_2(C_6H_5)_2$ and $S_2(C_6F_5)_2$ (1 mole each) gave the expected three products (I, II and III) which were readily separated by preparative scale thin-layer chromatography on kieselguhr using petrol ether as eluent The yields of products were very close to the ratio 1 2 1 (I II III) expected if the bridging ligands were little influenced by the group R, a ready interchange of ligands was also observed if either I or III was treated with S_2R_2 It is interesting to note that the melting-decomposition points of I, II and III were all 140°–143° C, mixed melting points of any two were some 20°–30° C lower.

The thermal decomposition of III in a sealed tube at 160° C gave carbon monoxide and decafluorobiphenyl as the only isolable products Attempts to remove the sulphur ligand from the iron by heating III with mercury failed, decafluorobiphenyl again being formed, this is in contrast to the free ligand $S_2(C_6F_5)_2$ [and $Se_2(C_6F_5)_2$] which reacts with both mercury and germanium on heating

$$S_2(C_6F_5)_2 + Hg \xrightarrow{180°} \underset{\text{m p } 188°\text{–}190° \text{ C}}{Hg(SC_6F_5)_2} \xrightarrow[200° \text{ C}]{Cu} Hg(C_6F_5)_2$$

$$Se_2(C_6F_5)_2 + Hg \xrightarrow{180°} \underset{\text{m p } 171°\text{–}173° \text{ C}}{Hg(SeC_6F_5)_2} \xrightarrow[200° \text{ C}]{Cu} Hg(C_6F_5)_2$$

$$S_2(C_6F_5)_2 + Ge \xrightarrow{\quad} \underset{\text{m p } 143°\text{–}145° \text{ C}}{Ge(SC_6F_5)_4}$$

Mixed aromatic/fluoroaromatic acetylenes, $\varphi_F C\equiv C\varphi$, react with cobalt carbonyl in a manner similar to diphenyl acetylene[3], the fluoroaromatic group having little influence on the reaction Typical compounds synthesized are

$(4\text{-}C_6F_5C_6F_4C\equiv CC_6H_5)Co_2(CO)_6$, m p 140° C (decomp)
$(4\text{-}ClC_6F_4C\equiv CC_6H_5)(Co_2(CO)_6$, dark red oil
$(4\text{-}C_6H_5C\equiv CC_6F_4C\equiv CC_6H_5)Co_2(CO)_6$, dark red oil

In the latter case, where two acetylene groups are present, it is possible to isolate a rather unstable solid (decomposes without melting at 156° C) which has two cobalt atoms attached to each acetylenic bond

RADIOBIOLOGY

Failure of Chinese Hamster Cells to repair Sub-lethal Damage when X-irradiated in the Plateau Phase of Growth

THE ability of exponentially growing Chinese hamster cells to repair sub-lethal damage induced by X-irradiation was shown by Elkind and Sutton[1] These workers showed that a dose of X-rays killed cells more efficiently when administered in one acute irradiation than when given in two fractions separated by a time interval The survival curve for the latter (with time between the two doses as variable) showed an early rise which was interpreted by Elkind as repair, the cyclic fluctuations following repair being a result of cell-cycle associated kinetics[2]

Repair of sub-lethal damage has since been observed in many cell systems and under a variety of experimental conditions In fact, one of the interesting features of this phenomenon is that it can take place in situations in which many other cell processes are inhibited low temperatures[3], in conditions where the cells are hypoxic[4], and in the presence of agents inhibiting DNA and protein synthesis (although RNA synthesis may be required[3]) All these experiments were performed with cells which had been actively growing It now seems, however, that cells in crowded culture conditions progressively lose their repair capacity even in the absence of specific inhibitors

Chinese hamster cells (strain *HA*-2) were plated on plastic Petri dishes The medium (Eagle's minimal essential medium, supplemented with 15 per cent foetal calf serum) was changed daily In such conditions, the cultures formed dense monolayers with about 10^7 cells on a 60 mm dish This cell number did not increase if the medium was exchanged more frequently Many properties of these cultures as well as detailed experimental procedures are reported elsewhere[5,6]

Fig 1 shows survival curves of X-irradiated cells (technical factors 120 kV, 9 mA, 67 rads/min, 1 mm Al filtration) The ability to form colonies was used as the criterion of survival The slopes of the linear portions of the two curves do not differ significantly, but the extrapolation number ($\bar{n}$) of the survival curves obtained from cells irradiated in plateau phase is significantly lower

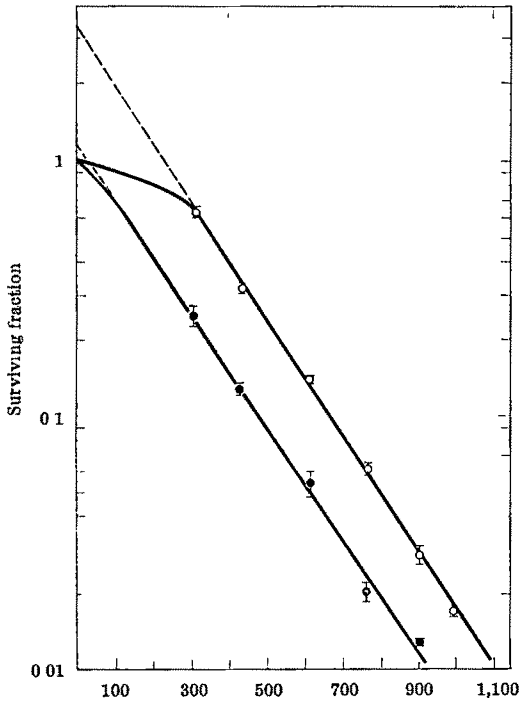

Fig 1 X-ray survival curves of Chinese hamster cells (*HA*-2) ○, Cells from cultures irradiated in exponential period, $D_0 = 142\ 3 \pm 4\ 3$ rads, $\bar{n} = 2\ 8 \pm 0\ 2$ ●, Cells from cultures irradiated in plateau period, $D_0 = 136\ 4 \pm 0\ 68$ rads, $\bar{n} = 1\ 2 \pm 0\ 4$ Vertical bars ±1 *S E*

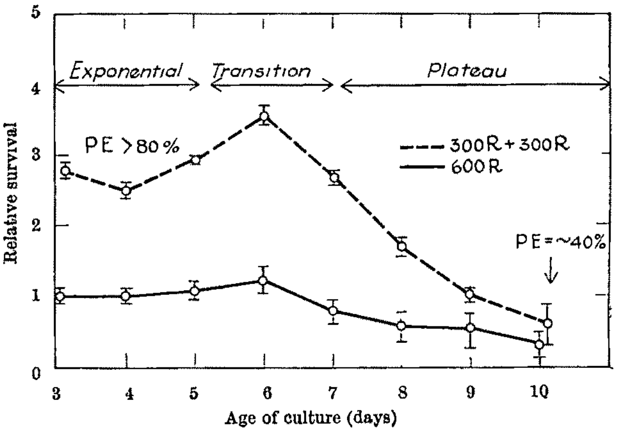

Fig 2 Repair ability in various growth phases Replicate dishes were seeded with equal number of cells on day 0 Medium was changed daily beginning with day 3 Cells were irradiated daily on and after day 3 Fractionated doses (○ - - - ○) were separated by 3 h In parallel, a growth curve was constructed to determine growth periods of the cultures The periods are defined operationally with respect to cell doubling time exponential (doubling time constant), transition (doubling time increased with increasing age of culture), plateau (doubling time long, not measurable) Vertical bars ±1 *S E*

The magnitude of the extrapolation number has been related to the amount of sub-lethal damage a cell can repair[1], the reduction in $\bar{n}$ during the plateau phase should therefore be accompanied by a loss of ability to repair damage This is indeed the case and the progressive reduction of repair with age of the culture is indicated in Fig 2 The lower curve represents survival of cells from replicate cultures irradiated with 600 rads at different stages of growth of the cultures Survival values were normalized to unity during exponential growth The reduction in level of absolute survival with culture age is a reflexion of the reduction in $\bar{n}$ The upper curve was obtained from cultures similarly treated but irradiated with a split dose (2 × 300 rads) separated by 3 hours During exponential growth, fractionation resulted in a threefold increase in survival The effect of fractionation decreased with culture age until the two curves became indistinguishable

In order to rule out the possibility that repair occurred more slowly in plateau phase cells, or that the repair effects were counteracted by kinetic factors peculiar to the 3 h interval, a split dose-response curve was obtained from cells which had been in plateau phase for 4 days (Fig 3) The lower curve in Fig 3 does not show the early repair-associated rise, and the cyclic fluctuations seen in the split dose response from exponentially growing cells (upper curve) are absent As has been said earlier, these survival fluctuations are associated with cell cycle progression Most of the plateau phase cells are in a *G*-1 part of the cell cycle[5] and therefore no cell cycle progression effects are observed

At the present time no explanation can be offered as to why this progressive loss of repair ability occurs when these cells are in plateau phase The phenomenon does not correlate with changes in DNA, RNA or protein synthesis[5] The only other quantity that we have measured which does change progressively is viability For example, in one experiment, plating efficiency dropped almost linearly from 80 per cent to 40 per cent during 4 days of plateau phase If the cells were sub-cultured and re-seeded in less crowded surroundings, both repair capability of the surviving cells and their plating efficiency were restored within 12 hours

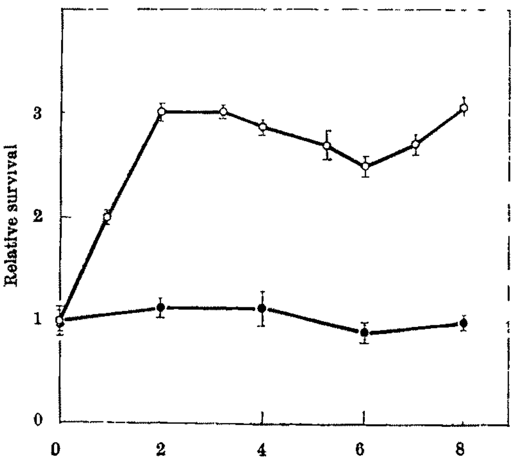

Fig 3 Two-fraction response of Chinese hamster cells ○, Cells in exponential period (day 5 of Fig 2) ●, Cells in plateau period (day 10 of Fig 2) All cells were irradiated at time 0 with 300 rads without sub-culturing and dishes were returned to incubator An additional 300 rads was then given at various times from 0 h to 8 h Sub-culturing to test for survival was done approximately 30 min following second irradiation Vertical bars ±1 *S E.*

Radial Diffusion and Power Function Retention of Alkaline Earth Radioisotopes in Adult Bone

THE retention of alkaline earth radioisotopes in skeletal systems can be approximated by the power function[1]

$$R = \varepsilon^{b} (t + \varepsilon)^{-b} \tag{1}$$

where b is a fraction between 0 0 and 0 5, t is the time after intravenous injection and ε is a short time which for adult dog and man is the order of 1 day A physiological explanation for this form of retention function is now presented which may be applicable to normal adult bone

Suppose that at times which are long compared with ε the principal effect on tracer retention is the transfer of tracer ions between the blood and existing volumes of bone, the diffuse component[2], rather than the formation or resorption of bone This supposition seems to hold for adult dogs[3,4] and rabbits[5] The diffuse component has also been observed in man, but whether it has a dominant effect on retention has not been established

To reach the volume of existing bone the tracer must pass through canaliculi, longitudinal flow of tracer along canaliculi occurs in the liquid phase and so is relatively rapid According to this new explanation, there is, then, a diffusion radially outwards from each canaliculus, this is very slow because it takes place in the essentially solid calcified matrix Retention of tracer in this process is long because there is a large mass of mineral with which to exchange Furthermore, retention is enhanced by the geometry of the cylinder, because once an ion has left the cylinder axis it is improbable that it will return by a random path The retention problem is therefore similar to that for the diffusion of an instantaneous source of tracer from the axis of a cylinder

Consider a long cylinder with a very small canal running along the cylinder axis If a diffusible tracer is distributed uniformly along the canal at time zero, the amount of tracer remaining in the canal as a function of time can be calculated by solving the diffusion equation in cylindrical co-ordinates

$$\frac{\partial C}{\partial t} = D\left[\frac{\partial^2 C}{\partial r^2} + \frac{1}{r}\frac{\partial C}{\partial r}\right] \tag{2}$$

where C is the concentration of tracer as a function of time t at any radius r and D is the coefficient of diffusion[6] For the initial conditions given here, the solution of equation (2) for the concentration of tracer at $r = 0$ is

$$C = \frac{q'}{4\pi D t} \tag{3}$$

where q' is the initial quantity of tracer per unit length deposited along the axis at $t = 0$ (ref 6) The quantity of activity remaining in the canal depends exactly on the power function t^{-1} If the canal is assumed to have a non-zero diameter, C remains finite at time zero The difference between t^{-1} and the functions $t^{-1\ 2}$ to $t^{-1\ 5}$ observed for blood specific activities[1] at times that are long compared with ε can be explained as the effect of excretion

The effect of excretion on equation (2) can be taken into account by introducing a small drain on the axial canal after instantaneous labelling This analysis was performed on the 'PACE' analogue computer using an eighteen compartment series model The differential equations for the model reduced to equation (2) as the number of compartments was made large Furthermore, when the drain was set equal to zero, the analogue com-

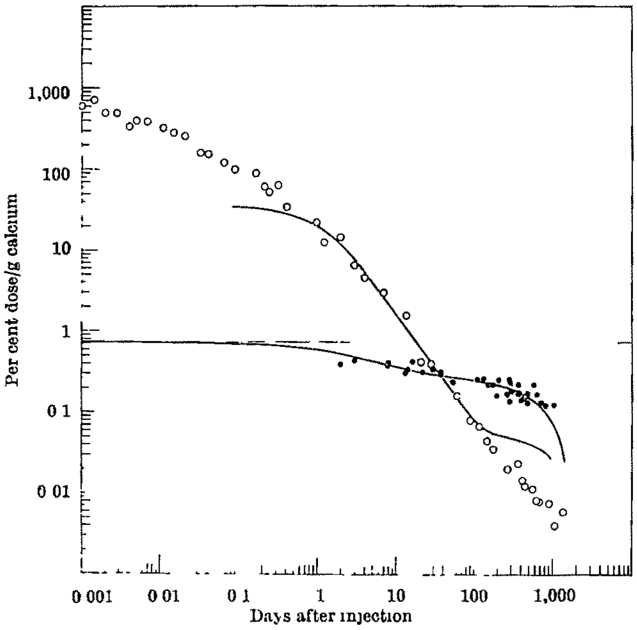

Fig 1 Data for radium-226 in the plasma (○) and in the body (●) of beagles injected at 1 3 years of age[7] The curves (——) show the corresponding analogue computer results for the specific activity of canalicular fluid and of the body as a whole, considered as a large number of canaliculi together with their surrounding territories C = 135 g calcium, 10 mg/100 ml

puter yielded a t^{-1} dependence for axial activity as in expression (3) This provided a check on the model. When the drain was increased, a series of curves for axial activity against time was produced which could be well approximated by a set of power function expressions varying continuously from $t^{-1\ 0}$ to $t^{-1.5}$. We assume that the specific activities of blood and canalicular fluid are equal at times which are long compared with ε Because the specific activity of blood is proportional to the time derivative of retention[1], the corresponding retention curve can be approximated by t^{-b} with b between 0 0 and 0 5 When the drain was adjusted to a value consistent with the endogenous excretion rate for radium-226 in dogs, the model gave a good fit to the data of Van Dilla *et al.*[7] over three decades of time as shown in Fig 1

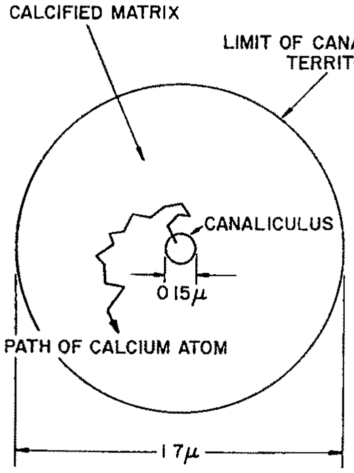

Fig 2 Radial diffusion of an atom of calcium or other alkaline earth from a canaliculus into the surrounding territory of calcified matrix The dimensions are from Baud's[8] electron microscope measurements of mouse bone

We picture this radial diffusion as involving a penetration of alkaline earth ions through a complex material consisting of collagen, ground substance, amorphous component and embedded bone crystals (Fig 2) We have taken the diameter (0 15μ) and average spacing (1 7μ) of canaliculi from electron microscope measurements of mouse bone[8] The data for calcium-45, strontium-90 and radium-226 in adult dogs[1] can be fitted with an effective coefficient of diffusion of the order of 10^{-16} cm^2/s At this rate, it would take almost a year for an ion to diffuse from a canaliculus to the limit of canalicular territory The theory therefore represents a marked departure from the common hypothesis that the typical bone crystal is bathed by extracellular fluid which is in fairly rapid exchange with the blood

It may be possible to test this theory of slow radial diffusion by carefully timed electron microscope autoradiography

This work was carried out under the auspices of the US Atomic Energy Commission

Effect of Ecdysone on the Puparium Formation in Irradiated *Ephestia kühniella* Z.

COMPLETE inhibition of metamorphosis and pupa formation is observed in some insect species when they are irradiated with 20 kr. and more of γ and X-rays[1]. Puparium formation is delayed in *Ephestia kuhniella* by doses of 20–30 kr [2-4]

The absence of pupation might be explained by radiation damage to the hypodermis nuclei and by the inability of DNA to give any new genetic information (under the influence of the pupation hormone ecdysone)[4] It may also be caused by a disturbance of neurosecretory cell activity and the absence of ecdysone in the body of the caterpillar To find the true reason for the absence of pupation we have studied puparium formation in irradiated larvae after the injection of ecdysone.

Larvae of *Ephestia kuhniella* Z , 7 and 2 days before pupation, were given 30 kr. of gamma rays. Another group was irradiated with 150 kr 2 days before they were due to pupate Ecdysone, isolated by the method of Butenandt and Karlson from pupae of *Bombyx mori*[5], was injected into the irradiated larvae just at the time of puparium formation. High concentrations of ecdysone were used because of the low sensitivity of *Ephestia* to this hormone, 0 5–1 0 mg (in 0 005–0 01 ml) was injected. The activity of the preparation of ecdysone was determined by the method of Karlson[6]; 48 h after injection fourteen abdomens showed 64 per cent pupation After being tested in this way ecdysone was injected into irradiated larvae Water was injected into controls

Features of pupation were shortening of the body into a triangular shape, induration and the appearance of dark-brown pigment in the cuticle.

Table 1. EFFECT OF ECDYSONE ON PUPARIUM FORMATION IN IRRADIATED *Ephestia kühniella* Z.

				Pupation				
Preparation injected, weight	Dose (kr)	Time after irradiation	No. of larvae	Slight	Active	None	Total No of pupated animals	Pupation (per cent)
Water								
0 005 ml	30	48 h	10	0	0	10	0	0
0 01 ml	30	48 h	10	0	0	10	0	0
Ecdysone preparation								
0 5 mg	30	48 h	10	2	2	6	4	40
1 mg	30	48 h	9	5	1	3	6	66
0 5 mg	30	7 days	4	0	2	2	2	50
1 mg	30	7 days	4	1	1	2	2	50
1 mg	150	48 h	29	4	0	25	4	13

The results in Table 1 show that the injection of an ecdysone preparation induced the formation of the puparium in irradiated insects. Injection of water had no effect, and so the activation of genes by ecdysone and the specific synthesis of *m*RNA and pupation enzymes take place after the injection of an ecdysone preparation to irradiated larvae, as observed in normal conditions under the effect of endogenic ecdysone[7]

Thus the absence of puparium formation in the irradiated larvae (given 20–30 kr) results not from a disturbance of the DNA of the hypodermis but from the absence of ecdysone Absence of ecdysone, in its turn, is evidently the result of irradiation damage to neurosecretory cells The macromolecular system necessary for puparium enzyme synthesis was rather radioresistant The disturbances were observed only under the effect of 100–150 kr of irradiation

MICROBIOLOGY

High Titre T Antigen with Minimal Amounts of Structural Antigen in Adenovirus-infected Cells treated with Hydroxyurea

Virus-specific non-structural antigens (T antigens) are produced early in the lytic cycle of adenovirus infection and are also found in cells transformed by adenovirus[1–3] Synthesis of T antigen, unlike that of the structural antigen, is not dependent on DNA synthesis, for example, fluorodeoxyuridine (FUdR) effectively inhibits the synthesis of viral antigen (V) without markedly suppressing the production of T antigen[4,5] Our studies have been designed to produce large quantities of T antigen "free" from viral structural antigen by manipulation of the lytic interaction of adenoviruses in *KB* cells

In the *KB* line at present used in this laboratory (originally obtained from Dr H S Ginsburg), FUdR markedly reduces V titres, but the residual V titres are still too high for a serologically useful T antigen preparation, similarly, cytosine arabinoside at 100 µg/ml of medium, even freshly added at 12 h intervals, does not alter the production of V antigen Other approaches such as the use of virus particles partially inactivated by ultraviolet light and the incubation of infected cultures at sub-optimal temperatures[6] have also been found effective in separating the synthesis of T and V antigens These procedures however, require careful control of a variety of experimental variables and for this reason a more reliable method is desirable

Hydroxyurea, an inhibitor of DNA synthesis, interferes with duplication of some DNA viruses[7–9] Its present use seems to provide an effective method of fulfilling the objective stated here

Washed *KB* monolayers (approximately 4×10^6 cells) in milk dilution bottles were exposed for 1 h at 37° C to various multiplicities of adenovirus type 7 ($10^{8\ 3}$ $TCID_{50}$/ ml in human embryonic kidney cells) A range of concentrations of hydroxyurea (Nutritional Biochemicals Corporation, Cleveland, Ohio) was prepared in Eagle's basal medium supplemented with 5 per cent foetal bovine serum, 2 per cent glutamine and antibiotics Following removal of unabsorbed virus, 20 ml of medium containing hydroxyurea was added to the experimental cultures which were subsequently incubated at 37° C

After 24–72 h, the cells were scraped into the medium with a rubber policeman and were centrifuged at 2,000 r p m for 10 min at 4° C After decanting the supernatant fluid, the cells were washed in balanced salt solution and re-pelleted The last traces of fluid were removed and the cell packs frozen at −70° C until tested by the microtitre complement-fixation technique[2,10]

Table 1 EFFECT OF HYDROXYUREA ON FORMATION OF T AND VIRAL STRUCTURAL ANTIGEN (V) IN *KB* CELLS INFECTED WITH ADENOVIRUS 7

0	3	< 2	< 2	< 2	< 2	< 2	< 2
0	0	< 2	< 2	< 2	< 2	< 2	< 2

An example of the results of several experiments (Table 1) shows that a high input of virus in the presence of appropriate concentrations of hydroxyurea will result in high titres of T antigen with minimal or no formation of detectable adenovirus group-specific (hexon, V) antigen Haemagglutination studies indicate that type-specific (penton) synthesis is also effectively suppressed by hydroxyurea At lower virus inputs, similar results are obtained particularly with lower concentrations of hydroxyurea and later times of cell collection Note the high titre of T antigen in the absence of detectable V antigen obtained at 3 days with a viral input of 0 5 and 2 mM hydroxyurea (Table 1) The reduced titre of T antigen produced with some concentrations of hydroxyurea probably reflects the suppressive effects of this drug. at those concentrations, on RNA and protein synthesis[8]

Preliminary experiments with adenovirus types 2 (Table 2) and 12 in *KB* cells suggest that similar results may be expected for all human adenoviruses and perhaps even infra-human types The use of hydroxyurea provides a relatively simple method for the production of large amounts of T antigen (free of significant viral structural antigen) for purification and functional studies In a recent experiment, a 40 per cent suspension of pooled cell pack from multiple cultures (25 ml) gave a complement fixation

In vitro Characteristics of a Poxvirus isolated from Rhesus Monkeys

PRIMATES are susceptible to poxviruses of the variola–vaccinia–monkeypox group and to Yaba poxvirus. When an epidemic of skin lesions with the clinical characteristics of vaccinia appeared in rhesus monkeys (*Macaca mulatta*), Japanese macaques (*Macaca fuscata*) and animal personnel in our colony, monkeypox was suspected. Electron micrographs of biopsied skin lesions showed particles resembling poxvirus[1,2]. The agent, subsequently isolated in tissue cultures, is, however, morphologically and serologically distinct from the vaccinia group, and the histopathology is totally different from that of Yaba virus. We therefore think that this agent, temporarily called '1211', is a new unclassified poxvirus which is infectious for primates and may be the same as that recently reported from Texas[2].

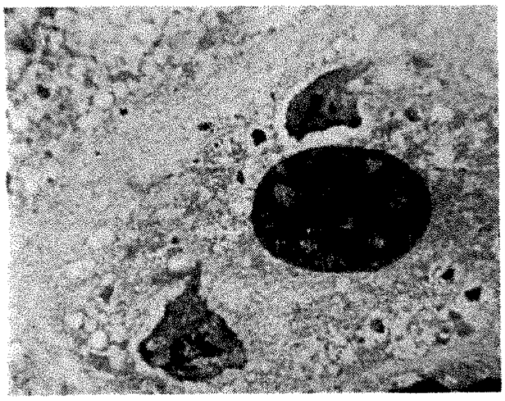

Fig. 1. '1211' virus in human amnion cell culture 7 days after infection. (× c. 465.)

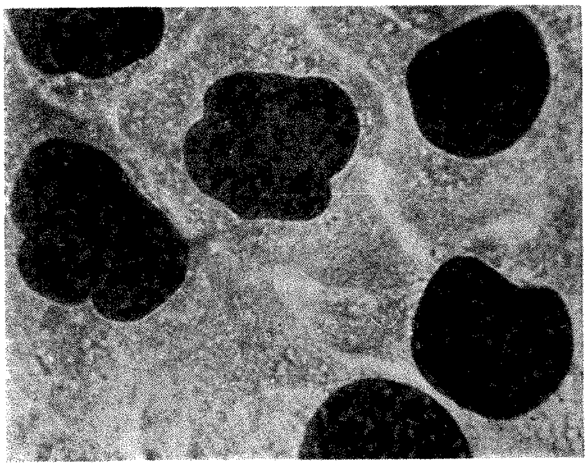

Fig. 2. Uninfected human amnion cell culture after 7 days. (× c. 465.)

An extract of a homogenized skin lesion did not produce pocks on chick chorioallantoic membrane and no cytopathic effects were observed in HeLa cells, chick embryo cells or rabbit kidney cells. Cytopathic changes were produced in cultures of *BS-C*-1 (ref. 3), human amnion, rhesus amnion and rhesus epidermal cells after incubation for more than 10 days. The time of appearance of these changes shortened to 4–5 days after repeated passage. After eight passages, sonicated cells and culture medium were scarified into rhesus monkey skin and caused lesions clinically and histologically identical with the original disease.

The *BS-C*-1 cells are suitable for plaque assay under agar, although plaques cannot be seen for 4–6 days, are counted after 8–10 days and remain less than 1·0 mm in diameter. Cells and medium sonicated at the time of maximum cytopathic change yield 10^5–10^6 plaque forming units (PFU)/ml.; the virus can be concentrated and purified in sucrose density gradients[4] and thus produce a titre of 10^7–10^8 PFU/ml.

Primary human amnion cells stained with Giemsa show numerous cytoplasmic inclusions 5 days after infection with '1211' virus and nuclear vacuoles after 6 days (Figs. 1 and 2). The cytoplasmic inclusions probably contain virus; in electron micrographs of biopsied skin lesions, similar inclusions are seen to contain virus particles and these are found only in the cytoplasm. The significance of the nuclear vacuoles is unknown; they have been noted in cell cultures infected with sheeppox[5], myxoma[6] and swinepox[7], but not with Yaba[8] or monkeypox[9].

Results of preliminary serological comparisons by neutralization and complement fixation are shown in Tables 1 and 2. Hyperimmune rabbit sera were collected after serial injection with virus that had been grown in cell culture, purified by gradient centrifugation and inoculated at 10^7 PFU per injection for '1211' virus and 10^9 PFU for vaccinia and monkeypox. Sufficient quanti-

Table 1. SEROLOGICAL COMPARISON BY NEUTRALIZATION

	Serum titres*			
Virus	Monkeypox	Vaccinia	'1211'	Yaba†
Monkeypox	6,400	3,200	< 10	ND

ties of other poxviruses are not yet available for preparation of sera.

The morphological differences in cell cultures and lack of serological cross-reaction clearly set '1211' apart from the variola–vaccina–monkeypox sub-group of poxviruses. Cross-reactivity with Yaba virus is apparent, but quantitation of this relationship awaits volume growth and reliable plaque assay of this virus in our laboratory.

Combined Lethal Effect of Zinc Chloride and Gamma Irradiation on *Bacillus megaterium*

IT has been known for several years that zinc chloride, like the salts of other heavy metals, has a lethal effect on bacteria[1–5]. Inactivation of micro-organisms by irradiation has also been extensively studied[6–10], and yet the effect of the combination of these two inactivating agents has received little attention.

The addition of radioactive zinc-65 to cultures of *B. megaterium* in the exponential phase of growth has been shown to be inhibitory, while non-radioactive zinc, in the same concentration, had little or no effect[11]. In the experiments described here, zinc, combined with gamma irradiation, had a synergistic inhibitory effect on the ability of *B. megaterium* to form colonies.

Cultures of *B. megaterium* (strain Elstre) were maintained in the logarithmic phase of growth for 18 h at 37° C in nutrient broth (Difco), until the optical density of the cultures was about 0·150. From this culture, 0·5 ml. of bacterial suspension was taken and diluted in 9·5 ml. of nutrient broth, and irradiated at room temperature with gamma rays from a 500 Ci cobalt-60 source. The tubes containing culture were randomly placed in a circular device which rotated around the source. The dose rate was approximately 400 rads/min given for 5, 15 or 60 min, corresponding to 2,000, 6,000 and 24,000 rads, respectively.

Zinc chloride was added to bacterial suspensions, prepared and diluted in the same way, to give concentrations of 6×10^{-6} or 12×10^{-6} M in the medium. Bacteria were left in the samples containing zinc chloride for 45, 60 or 120 min.

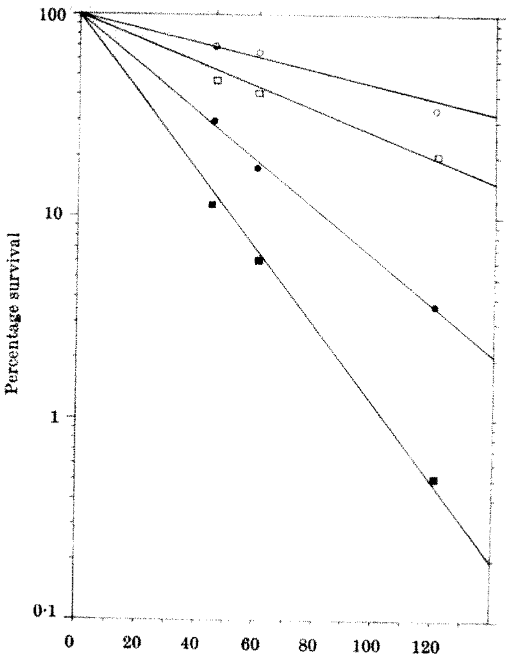

Fig. 1. Inactivation of *Bacillus megaterium* after exposure to two different concentrations of zinc chloride, for various times, and subsequent irradiation. ○, 6×10^{-6} M zinc chloride; ●, with irradiation; □, 12×10^{-6} M zinc chloride; ■, with irradiation.

Another series of tubes, with exposures similar to those of zinc chloride, were also irradiated as described. Surface plate counts were made on Difco nutrient agar before and after irradiation and the colonies were counted after incubation at 35° C for 48 h.

Survival curves of samples containing various concentrations of zinc chloride, of samples irradiated at different doses, and of samples containing zinc which were then irradiated, are shown in Figs. 1 and 2. The effect of zinc chloride and gamma irradiation on the survival of the micro-organisms is also shown in Table 1.

The chemical agent remained in contact with the cells for quite a long time and was moderately toxic to them. By increasing the time of exposure, as well as the concentration of the chemical, the toxicity was increased. Thus exposure to zinc chloride alone for 45, 60 or 120 min at a concentration of 6×10^{-6} M decreases the percentage of survivals to 70, 66 or 34 per cent, respectively. At a stronger concentration (12×10^{-6}) and with the same exposures, the percentage survivals decreased to 45, 40 or 20 per cent, respectively. Gamma irradiation alone causes a significant decrease of survivals and here also the reduction is directly related to the dose. Approximately 28, 45 and 85 per cent of the bacilli lost the ability to form new colonies when irradiated with 2,000, 6,000 and 24,000 rads, respectively. For comparison, the percentages of survivals here are 72, 55 and 15 per cent, respectively.

Table 1. SURVIVAL PERCENTAGE OF *Bacillus megaterium* AFTER ZINC TREATMENT, GAMMA IRRADIATION AND COMBINATION OF EXPOSURES TO ZINC AND GAMMA RAYS

Time (min)	Zinc chloride		Zinc chloride + gamma irradiation		Gamma irradiation 400 rads/min	Dose (rads)
	6×10^{-6} M	12×10^{-6} M	6×10^{-6} M	12×10^{-6} M		
0	100	100	100	100	100	0
45	70 ± 6·1	45 ± 5·8	30 ± 4·9	11 ± 2·8	72 ± 3·6	2,000
60	66 ± 5·9	40 ± 5·7	17 ± 2·1	6 ± 1·5	55 ± 3·2	6,000
120	34 ± 3·6	20 ± 3·6	3·7 ± 0·9	0·5 ± 1·6	15 ± 1·8	24,000

When zinc treatment and gamma irradiation are combined, the decrease of survivals is more important. With zinc chloride at a weak concentration and after irradiation with 2,000, 6,000 and 24,000 rads, the percentage survivals

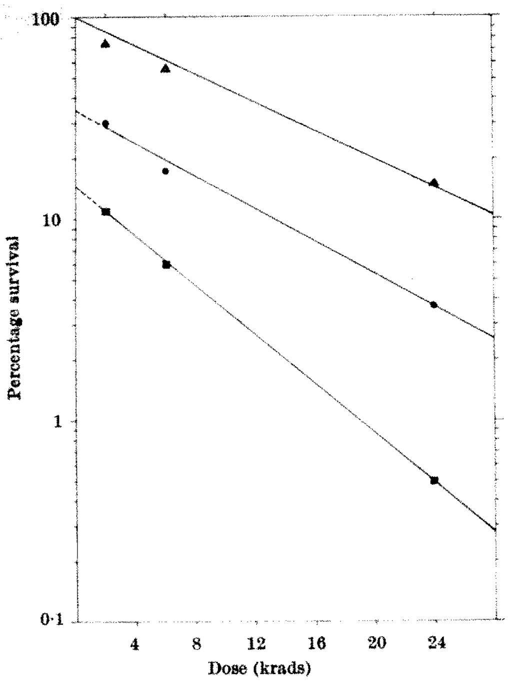

Fig. 2. Effect of gamma irradiation at various doses alone or with two different concentrations of zinc chloride, on survival of *B. megaterium*. ▲, Irradiation (400 rads/min); ●, irradiation and zinc chloride (6×10^{-6} M); ■, irradiation and zinc chloride (12×10^{-6} M).

are 30, 17 or 3·7, respectively. With the stronger concentration of zinc and the same irradiation doses the percentage of survivals diminishes to 11, 6 or 0·5, respectively. This clearly demonstrates a synergistic effect of the metal ions and the radiation. Even by supposing that the two agents reach different targets in the cells, the expected total decrease of survivals after the combined action is much lower than the observed one.

Metal salts, in concentrations which are not toxic, are known to increase the resistance to ionizing radiations. It has been suggested and partly supported by experimental evidence that ions of those metals as well as more complex redox systems increase the radioresistance by donating or receiving electrons. They thus facilitate the neutralization of active molecules which have gained or lost electrons during the ionization process[12]. Heavy metals in appropriate concentration, however, exert a deleterious effect on bacteria by combining with sulphydryl groups which are essential for the metabolism of the cell[1-3]. Reagents that combine with sulphydryls have been shown to increase radiation sensitivity, at least in some micro-organisms[13,14].

The synergistic effect of radiation and zinc shown by the experiments reported here could be attributed to similar phenomena. In other experiments, to be published later, the same synergistic effect was observed on the growth rate curve of bacteria. Thus the combination of the two inactivating agents seems to affect both cell growth and cell multiplication.

The mechanism of the synergistic phenomena cannot yet be explained, but zinc probably sensitizes the bacteria to the lethal action of the gamma rays. This apparent sensitization might also be caused by a combination of toxic injuries, induced by the salt and by the irradiation.

IMMUNOLOGY

DNA Synthesis in the Development of Antibody-forming Cells during the Early Stages of the Immune Response

THERE is considerable evidence that antibody-forming cells arise by mitotic division after injection of antigen, and that they continue to divide and produce antibody while differentiating (refs. 1–3 and unpublished work of N. K. Jerne, A. Nordin, C. Henry, H. Funi and A. Koros). According to this view, the many antibody-forming cells present at the peak of an immune response are derived by extensive proliferation from a relatively small number of precursors. It has been suggested, however, that plaque-forming cells which release 19*S* haemolytic antibody may develop from precursors without division[4-6]. If this is true it follows that lymphoid tissue must contain a large number of cells capable of being directly "switched on" for synthesis of a specific antibody. Experiments designed to test this point are described here.

CBA mice, 8–14 weeks old and of either sex, were injected intravenously with 2×10^8 sheep red cells. At the same time, they received an intraperitoneal injection of ^{3}H-thymidine (Radiochemical Centre, Amersham), 2 µCi/g of body weight, specific activity 5,000 mCi/mmole. Injections of ^{3}H-thymidine were given at 12 h intervals (Table 1) until the mice were killed, 2–4 h after the last injection. Four non-immunized mice received five similar doses of ^{3}H-thymidine for a period of 2 days before killing.

Table 1. PROPORTION OF LABELLED PLAQUE-FORMING CELLS IN THE SPLEEN OF MICE AT DIFFERENT TIMES AFTER IMMUNIZATION

Time after injection of antigen (h)	No. of mice used	Mean PFC/10^6 spleen cells	No. of PFC examined Labelled	Total
0	4	2	1	12
26–28	5	8	7	18
40	2	34	13	13
52	1	60	16	16
76	1	300	10	10
98–100	2	4,470	34	34

PFC, plaque-forming cells.

Single cell suspensions were made from the spleens of killed mice, and cells producing haemolytic plaques were identified, picked out and smeared individually using techniques described fully elsewhere[7,8]. Briefly, monolayers of spleen cells and target sheep erythrocytes were incubated in droplets of Eisen's medium[9] (with 10 per cent of foetal calf serum and 5 per cent guinea-pig complement) under paraffin oil. After incubation for 15–30 min, plaques developed in the monolayers; a single antibody-forming cell could be picked out from the centre of many of these with a micropipette. Where antibody-forming cells were rare, as in non-immunized animals, a two step procedure was necessary[8]: lymphoid cells were first incubated at relatively high concentration in the droplets, then all the cells from the centre of the plaque were removed, diluted and reincubated with more erythrocytes and complement in a second monolayer. The active cell could usually be identified after this second incubation. Plaque-forming cells were smeared in a very thin stream of serum blown from the micropipette and their position on the slide was marked by ringing with a diamond objective. Slides were then coated with Kodak *NTB*-2 emulsion and exposed for 19–22 days, after which the emulsion was developed and the cells were lightly stained with Giemsa.

Table 1 records that from 40–100 h after injection of antigen all plaque-forming cells were labelled (usually with more than thirty grains). These cells were mostly basophilic mononuclears of various sizes, with a few plasma cells[8]. By contrast, in the small sample of "background" plaque-formers from non-immunized mice, all but one were unlabelled, indicating that these cells or their precursors divide infrequently. The one labelled cell was a typical small lymphocyte. The others were also small cells (all of average diameter < 11μ), although usually more basophilic than typical small lymphocytes, with a nucleus occupying most of the apparent area of the smeared cells[8]. One was a plasma cell. At 26–28 h after antigen had been injected, the population was mixed by both morphological and labelling criteria. All eleven unlabelled cells were less than 12μ in average diameter, while the seven labelled cells were mostly larger (diameters were 10, 12, 12, 13, 17, 19, 21μ). The emergence of these labelled cells was presumably provoked by antigen. The unlabelled cells at this time may well have been background plaque-formers present before antigenic stimulation, although the data do not exclude the possibility that some of these may have begun to produce antibody only after antigenic stimulation and without dividing.

These results show clearly that after a mouse is immunized with sheep erythrocytes the great majority of IgM-producing cells synthesize DNA before releasing antibody. Sterzl[4] has reported experiments very similar in design to ours, except that ^{14}C-thymidine was used instead of ^{3}H-thymidine. In his mice, only 50 per cent of plaque-forming cells were labelled at 4 days after antigen. This low figure may be a result of differences in the technique used to detect labelled cells. Eidinger and Pross[6] have concluded that the very rapid increase in number of 19*S* plaque-forming cells which occurs in some tissues during a primary immune response can be explained only by recruitment of new cells into antibody production. This may well be partly true; many antigen-responsive cells are probably derived from a circulating pool in the blood[10]. Nevertheless, our observation that all plaque-forming cells were labelled at days 2, 3 or 4 after antigen shows that some DNA synthesis, and almost certainly at least one division, occurs between recruitment of a cell and antibody production. Tannenberg[5] concluded that the plaque-forming cells in his experiments did not undergo enough mitotic divisions to account for the observed increase in the number of antibody-forming cells. His assumption that cells which have been supplied constantly with ^{3}H-thymidine should incorporate much more label after several mitotic cycles than after only one or two, is difficult to accept on theoretical grounds. If a cell incorporates an amount x of tritiated thymidine into its DNA during one period of synthesis, it then loses $x/2$ at the subsequent mitotic division. After the next *S* phase, the total label in the cell becomes $x+x/2$, of which half is again lost in mitosis, and so on. The maximum amount incorporated cannot exceed $2x$. This means that the difference in grain count between cells after 2 and 10 mitotic cycles could be, at most, 25 per cent. (This calculation assumes even distribution of the labelled material throughout the pool of thymidine in the animal, which Tannenberg probably achieved by taking the precaution of continuously infusing his animals.) His results did show that most plaque-forming cells 4 days after antigen do contain label, although grain counts tended to be lower than ours. The lower counts may have been caused by the presence of a thin layer of agar over the cells which would have absorbed some of the emitted β-rays.

In conclusion, while we cannot exclude the possibility that a very small proportion of cells produce antibody without first synthesizing DNA, our results support the view that most IgM-plaque-forming cells arise by mitotic division.

CYTOLOGY

Sensitivity of Micrurgically Removed Chromosomal Spindle Fibres to Enzyme Disruption

THE physio-chemical nature of chromosomes and chromosomal spindle fibres isolated by micrurgy is being studied by enzyme disruption of these structures, recorded by phase contrast cinematography.

Using a modification of the technique of McClendon[1], chromosomes and chromosomal spindle fibres can be removed micrurgically from human cells *in vitro* by an incision in the cytoplasmic membrane[2]. Groups of chromosomes along lengths of chromosomal spindle fibres can then be separated by teasing them with microneedles. Alternatively, one microneedle can be used to stabilize a mitotic cell while the other microneedle is inserted to pull out lengths of spindle with attached chromosomes[3] (Fig. 1).

With either approach, the isolated chromosomal spindle fibres show considerable elasticity when the surrounding solution is Hanks' BSS, Earle's BSS or Eagle's basic medium with or without the addition of serum. In Hanks' BSS, the spindle can be stretched over distances greater than 300μ before breakage occurs (Fig. 2*a*). Spindle fibres stretched up to 300μ may remain taut when relaxed to distances of about 100μ, showing their great elasticity (Fig. 2*b*).

When the surrounding Hanks' solution contains RNase 5× crystallized or pepsin 3× crystallized (Nutritional Biochemical Company) in concentrations of 2·5 mg/ml. the spindle can be stretched over 300μ (Fig. 2*c*), but on relaxation it does not return to less than 100μ. Instead, the relaxing spindle fibres form coiled configurations (Fig. 2*d*) indicating loss of elasticity and suggesting deformation of structure at the macromolecular level.

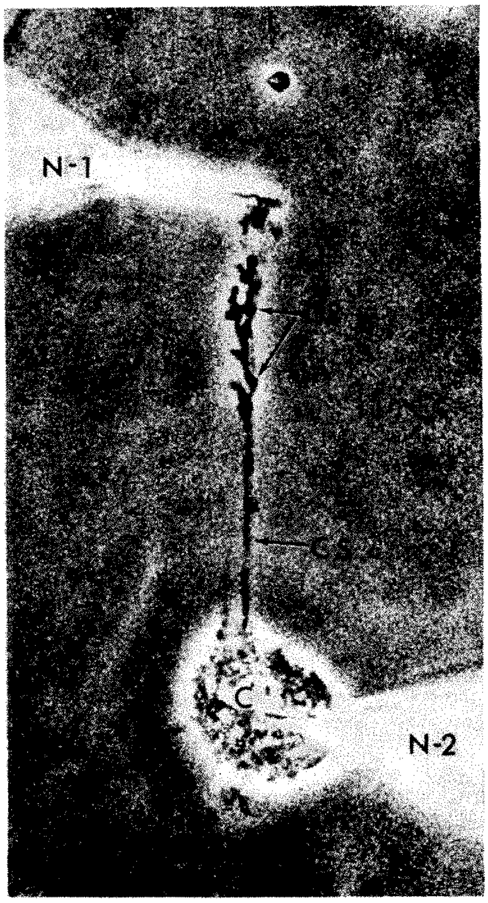

Fig. 1. Microneedle 1 (N-1) pulls chromosomal spindle fibres (CS) with attached chromosomes (CR) from cell (C) which is stabilized by microneedle 2 (N-2).

Spindle fibres isolated into surrounding Hanks' BSS and attached to the coverslip while stretched can be followed by cinematography, while the surrounding solution is changed to Hanks' BSS with 0·5 mg/ml. of DNase added. Within a few seconds of the change of solutions, the spindle fibres are seen to break and to become slightly less dense under phase contrast microscopy. Teasing with a microneedle shows that all stretchability is lost and no elastic recoil remains. When spindles are pulled out of cells into the DNase, they rarely survive long enough to stretch more than 50–100μ before breaking (Fig. 2*e*). (The fact that the spindle fibres do survive the first few seconds of isolation indicates that the cytoplasmic membrane is not significantly permeable to DNase during the 1–2 h periods of observation.) When the entire mitotic apparatus is isolated into this DNase solution, efforts to tease the chromosomes apart give the impression that the chromosomes are no longer connected by spindle fibres.

These studies indicate that the principal sources of strength and stretchability of chromosomal spindle fibres are susceptible to destruction by DNase but survive treatment with RNase and pepsin. Elastic recoil of these spindle fibres, however, seems to be reduced by the action of RNase and by pepsin.

Electron micrographic studies have shown mitotic spindle fibres (isolated by the method described here) as four groups of fibres attached to the kinomere in both mouse and human metaphase chromosomes[4]. These four groups of fibres appear to be each about 600 Å thick and each seems to be made up of smaller fibres which are bound into a fascicle by a yet smaller very dense spiralling fibre less than 100 Å thick[5] (Fig. 3). Of the fibres seen, only the dense spiralling fibre seems to be small enough to be a DNA strand. The larger fibres would then presumably be protein.

In electron micrographic studies, small dense fibres less than 100 Å thick, in sectioned chromosomes, were found to be sensitive to DNase[6]. In light microscopic studies of well stained Feulgen preparations such as those by Lima-de-Faria[7] (especially Figs. 40 and 41) some Feulgen positive material seems to taper off from the chromosome as if it were following the spindle. The studies described here suggest that not only does DNA

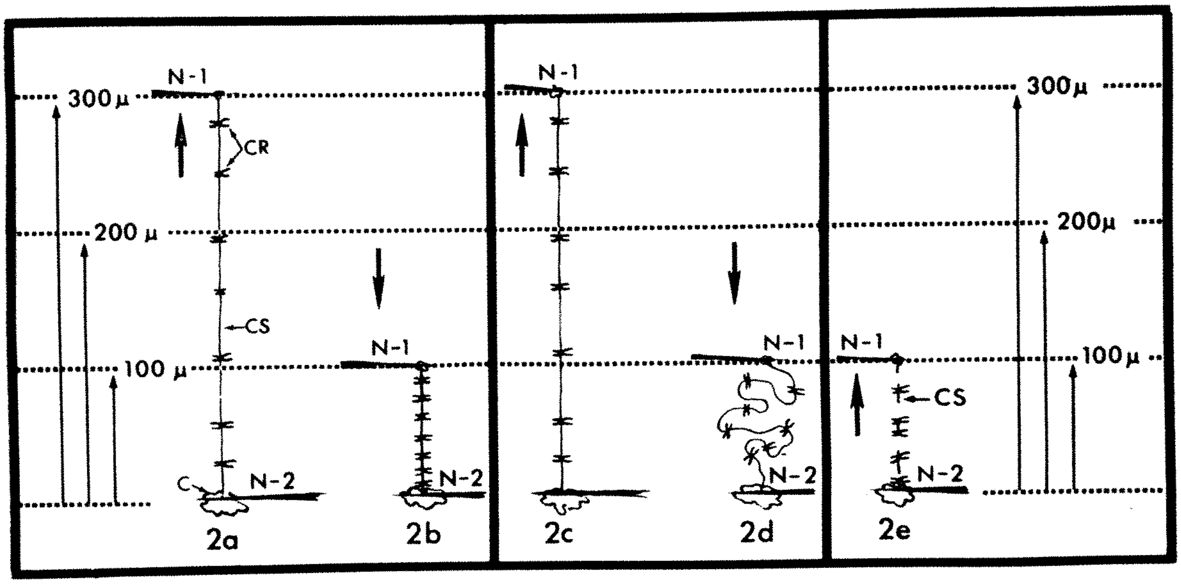

Fig. 2. A schematic representation of the studies described in the text. (*a*) Microneedle 1 (N-1) stretches chromosomal spindle fibres (CS) a distance of 300μ from the cell (C) which is stabilized by microneedle 2 (N-2). (*b*) When microneedle 1 (N-1) returns to within 100μ of microneedle 2 (N-2) the chromosomal spindle fibres remain taut as is characteristic for such fibres isolated into Hanks' BSS, Earle's BSS or Eagle's basic media. (*c*) Chromosomal spindle fibres (CS) can be stretched for a distance of 300μ in solutions containing RNase or pepsin (2·5 mg/ml.). (*d*) Chromosomal spindle fibres which have been stretched to 300μ in solutions of RNase or pepsin fail to remain taut when relaxed to 100μ. Instead they remain somewhat stretched and tend to coil as if macromolecular structures had been deformed. (*e*) Attempts to stretch chromosomal spindle fibres (CS) in solutions containing 0·5 mg/ml. of DNase fail because the fibres become disrupted and break within a few seconds of removal from the cell and exposure to the enzyme.

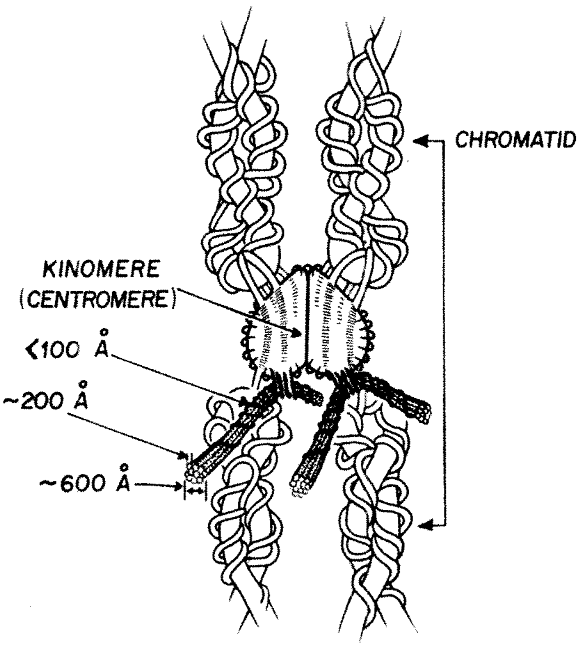

Fig. 3. A schematic representation of chromosomal spindle fibres as fascicles about 600 Å thick composed of fibrils about 200 Å thick surrounded by one or more dense spiralling fibre(s) less than 100 Å thick as they near the kinomere. The dense spiralling fibres are small enough to be DNA, and such fibres may be responsible for the structural integrity of the chromosomal spindle fascicles. (This drawing is not to scale.)

accompany the chromosomal spindle fascicles, but that DNA provides the chief source of structural integrity for these fascicles.

Apparent HeLa Cell Contamination of Human Heteroploid Cell Lines

INTERSPECIFIC cell culture contamination has been detected several times by karyotypic and immunological procedures[1–3]. These same measurements are of little value as detectors of intraspecific contamination, but polymorphic variants detectable at the cell culture level can be very useful for this purpose. A survey of twenty heteroploid human cell lines for glucose-6-phosphate dehydrogenase (G6PD) and phosphoglucomutase (PGM) electrophoretic polymorphisms revealed that all had the same G6PD and PGM phenotypes. These results were interpreted as reflecting widespread contamination of cultures by the first established human cell line HeLa. These findings were presented at the Second Decennial Review Conference on Cell Tissue and Organ Culture[4] and have since been extended to include other American Type Culture Collection lines. Further evidence on the stability of these markers in various conditions has been obtained, and in view of the widespread use of cell lines in a variety of investigations it seems important to make these findings readily accessible to other workers.

RL, Research laboratory; C, commercial source; ATCC, American Type Culture Collection.

There are two principal G6PD (sex linked) electrophoretic variants, the A (fast) and B (slow) types. The A type has been found only in Negroes, its frequency in the American Negro male population being about 30 per cent. There are three common PGM (autosomal) electrophoretic variants, 1, 1–2 and 2, with frequencies of approximately 65, 20 and 15 per cent in both Negro and Caucasian population. All the human heteroploid cell lines so far examined (Table 1) were found to have the G6PD A band and were PGM type 1. I have not ascertained the racial origin of all the lines examined; it is known, however, that at least some were thought to have been derived from Caucasians (*KB*, *WISH*, Prostate, *CMP*) and at least one (HeLa) is from a Negro. The absence of the A band in Caucasians excludes a statistically based sampling explanation of these results; however, even if all the lines are assumed to be of Negro origin the probability of all being G6PD A and PGM 1 by chance sampling is absurdly low (with values of 0·3 for A and 0·65 for PGM 1, the probability is 6×10^{-15}).

Two explanations for these observations may be considered: (1) G6PD or PGM expression or both are modified in established cell lines such that only the G6PD A and PGM 1 types are found; or (2) these lines are all or nearly all HeLa cell contaminants (HeLa being the first established cell line and derived from a Negro). To explore the first argument, a number of experiments were carried out to see if modification of G6PD and/or PGM expression was possible. Because heteroploid established cell lines are often associated with tumorous tissues, a number of tumours were studied to see whether the G6PD or PGM types of the tumour or both deviated from that of normal tissue in the same person. Tumours from more than 100 individuals have now been surveyed (leukaemias, fibromas, carcinomas of various tissues, trichoepithelioma and sarcomas); and in all cases the tumour phenotype was identical to the normal tissue phenotype. In the case of individuals heterozygous for G6PD (AB), tumours may show only the A or B phenotype; however, this is because of the cell mosaic nature of such heterozygotes and the possibility of single phenotype tumours developing through single cell origin or selection[5]. The tumour cases studied included all PGM types but only hemizygous and homozygous G6PD individuals. Several normal cell strains have been initiated from individuals of known G6PD and PGM genotypes and in all cases the phenotype of the culture throughout its life history *in vitro* has remained identical to that of the donor. G6PD and PGM phenotypes of normal cultures have been examined in a variety of culture conditions including PPLO contamination, *SV*40 infection, X-irradiation, 5-bromo-deoxyuridine incorporation and treatment with corticosteroids; in no case was the G6PD or PGM phenotype modified. Finally, two long term near diploid cell lines derived from tumours and maintained in culture for more than 3 years were both G6PD B. All evidence seems to point to the stability of the G6PD and PGM phenotypes both *in vivo* and *in vitro*.

The simplest and most likely explanation of these findings remains contamination from HeLa cells. Compatible with this argument is the derivation of the HeLa line from a Negro patient and the fact that it was the first established human cell line. If we assume that most, if not all, the heteroploid human cell lines are HeLa cell derivatives, then some important questions are raised regarding investigations with these cells. In cases where the investigator's requirement was for any human cell line, the problem of whether the line was HeLa, *KB* or Detroit does not seem important. In fact, differences between such lines for certain characters—virus sensitivity, for example—are perfectly compatible with a common origin of the lines, because *in vitro* developed variations within clones are well known in these systems. In those cases where the investigator has assumed a specific tissue origin of the cell line (liver or lymphocytes, for example), however, the work is of dubious value.

With the continued expansion of cell culture technology, it is almost certain that both interspecific and intraspecific contamination will continue to occur. The electrophoretic variants mentioned here are not only useful as intraspecific tags, but are even more powerful in species identification. The PGM pattern alone is specific for every species we have examined (man, hamster, rat, mouse, rabbit and cow). The use of stable genetic markers is routine practice in all genetically oriented stock keeping: now that such markers are available for cell culture work, their incorporation into the material to be cultured is the best guarantee against contamination.

PATHOLOGY

Anti-tumour Activity of S-Carbamyl-cysteine

L-ASPARAGINASE has been shown to inhibit the growth of various tumours in the mouse, rat and dog and is currently being used in clinical trials[1-5]. Unlike normal cells, the cells of tumours that respond to this enzyme have a requirement for the nutritionally non-essential amino-acid, L-asparagine.

Treatment of tumours with L-asparaginase is tempered, however, by the possibilities of reaction to foreign protein and of endotoxin contamination of the enzyme isolated from *E. coli*.

Several compounds structurally related to L-asparagine were therefore investigated in the hope that these analogues might interfere with the uptake and/or utilization of L-asparagine. *S*-Carbamyl-L-cysteine (SCC, Fig. 1), structurally related to L-asparagine and L-cysteine, was tested for anti-tumour activity *in vitro* and *in vivo* against tumours which were sensitive and non-sensitive to L-asparaginase. SCC has previously shown anti-tumour activity against a transplanted mouse adenocarcinoma[6].

S-Carbamyl-L-cysteine

Fig. 1.

S-Carbamyl-L-cysteine was tested *in vitro* against *L*5178*Y* and *L*1210 cells in static culture as previously reported[7]. Cell counts were taken at 24 and 48 h using a Coulter counter. The effects of SCC at various concentrations are reported in Table 1. SCC seemed to be equally cytotoxic against the *L*5178*Y* L-asparaginase sensitive and the *L*1210 non-sensitive cells.

Table 1. CYTOTOXIC EFFECT OF *S*-CARBAMYL-L-CYSTEINE AGAINST CELLS IN TISSUE CULTURE

Cell line	SCC concentration (μg/ml.)	Percentage inhibition of growth of controls at 24 h	at 48 h
*L*5178*Y*	50	97	99
	25	94	98
	10	35	40
	5	0	0
*L*1210	50	68	97
	25	61	88
	10	26	40
	5	0	0

Table 2. ACTIVITY OF *S*-CARBAMYL-L-CYSTEINE AGAINST VARIOUS TRANSPLANTED TUMOURS

Tumour	Range of doses used (mg/kg)	Optimal dose (mg/kg)	Percentage increase in median survival over control	Percentage inhibition of average control tumour weight
*L*5178*Y*	50–400 d* 400 eod†	400 eod	30	—
*L*1210	250–300 d 400 eod	400 eod	40	—
*P*388	300 d 300–400 eod	400 eod	37	—
*P*1798	200–300 d	300 d‡	—	70

* d, Daily.
† eod, Every other day.
‡ Five injections (day 1–5), mice killed on day 10 and tumours excised and weighed.

S-Carbamyl-L-cysteine was also effective against several tumours *in vivo* (Table 2). SCC seemed more effective in inhibiting the growth of the *P*1798, L-asparaginase sensitive lymphosarcoma than in increasing the median survival of mice bearing leukaemias sensitive (*L*5178*Y*) or non-sensitive to L-asparaginase. The mechanism of the anti-tumour effect of SCC is unknown, but it, or one of its metabolic products, may interfere with the oxidative energy supply supporting protein synthesis[8]. The equivalent activity of SCC against *L*5178*Y* and *L*1210 *in vitro* does not lend support to the hypothesis that SCC is an antimetabolite of L-asparagine.

Further studies on the mechanism of action of SCC and studies of the anti-tumour activity of other analogues of L-asparagine are in progress.

Reduced Binding of Carcinogenic Hydrocarbons to DNA of Mouse Skin during Inhibition of DNA Synthesis

CARCINOGENIC polycyclic hydrocarbons have been shown to bind to DNA in mouse skin[1-3], but no details are known of the conditions in which this binding occurs *in vivo*, for example the phase of the cell cycle, the functional status of DNA or whether the DNA is replicating or resting. Data are only available for *in vitro* binding to denatured and native DNA[3,4]. It could be assumed that replicating, histone-free DNA is a better target for hydrocarbons than resting DNA, in which case binding should be reduced if DNA synthesis is blocked. To test this idea we used hydroxyurea in different organisms[5,6]; this is a potent and rather specific inhibitor of DNA synthesis, and inhibits more than 90 per cent of DNA synthesis in mouse skin.

To measure DNA synthesis, 7 week old male NMRI mice were given ^{3}H-methyl-thymidine (1 μCi/g mouse intraperitoneally) and were killed 50 min later. The back skins (~7·7 cm^2) of these mice that had been previously shaved were scraped under liquid nitrogen, incubated in 3 per cent acetic acid overnight, homogenized and precipitated by 10 per cent trichloroacetic acid (TCA)[7]. After several washings with TCA, ethanol and ether, the residue was dried, weighed and burnt to give tritiated water which was counted in a liquid scintillation counter. The dose-response curve (thymidine incorporation against hydroxyurea) is shown in Fig. 1. All animals survived with a single dose of hydroxyurea of up to 0·66 mg/g body weight. Synthesis of DNA is effectively inhibited very quickly and remains so for 3–4 h (Fig. 2). When the effect of hydroxyurea wore off, DNA synthesis increased to more than the normal rate: if DNA synthesis has been blocked for 9 h the rate of DNA synthesis more than doubled after 24 h.

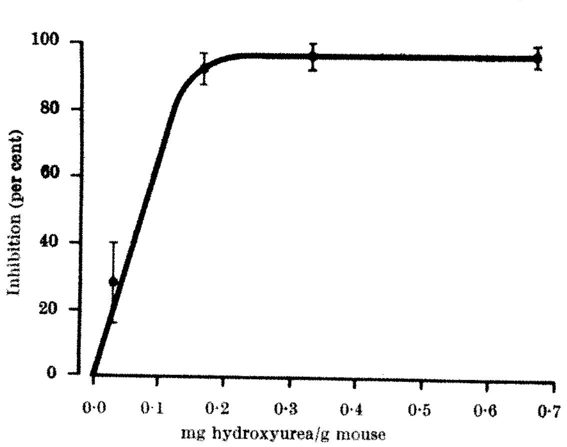

Fig. 1. Effect of different doses of hydroxyurea on DNA synthesis in mouse skin 70 min after intraperitoneal injection. Standard errors of the mean are indicated (four experiments).

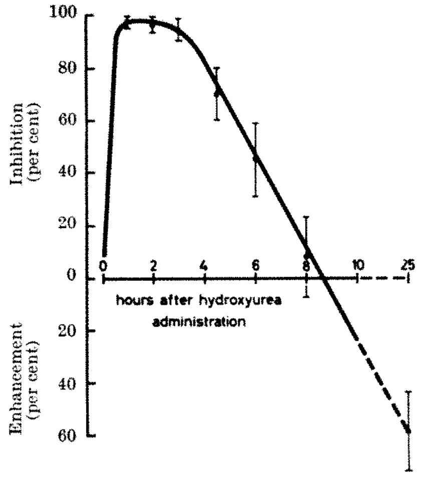

Fig. 2. Effect of hydroxyurea on DNA synthesis in mouse skin at different times after intraperitoneal injection (0·5 mg/g of mouse). Standard errors of the mean are indicated (four experiments).

A concomitant inhibition of RNA synthesis was not observed. This was followed by measuring the incorporation of ^{3}H-5-uridine (2 μCi/g intraperitoneally) according to essentially the same procedure as that described for thymidine. Thus hydroxyurea seemed to be a specific inhibitor of DNA synthesis in mouse skin as well as in other organisms[5,6]. To test whether DNA synthesis is essential for the binding reaction, five male mice were injected with hydroxyurea and incubated with tritiated 3,4-benzpyrene (BP) or 7,12-dimethylbenzanthracene (DMBA), dissolved in tricaprylin (0·3 ml./30 g of mouse). Unlabelled BP and DMBA were added to give a final concentration of hydrocarbon of 0·66 μM and 5 μCi/g of body weight, a dose known to produce tumours if later developed with croton oil. We preferred the oral route to local painting for two reasons: if hydrocarbons are locally applied, it is rather hard to eliminate residual hydrocarbons which might interact *in vitro* during the DNA isolation procedure. Furthermore, slight variations in the size of the painted area change the specific activities of labelled DNA considerably: the more untreated areas are included, the lower the specific activities will be. On the other hand, oral application ensures a rather more homogeneous distribution of hydrocarbons to mouse skin.

DNA was isolated after 4 or 12 h, a time which has been found to be long enough to allow maximum binding of BP or DMBA to mouse skin (unpublished results). The isolation procedure used was essentially that of Colburn and Boutwell[8]. RNA and proteins were removed by digestion with pancreatic RNase and pronase/trypsin. DNA preparations were characterized by the ratio of their wavelengths (260/280 usually > 1·83; 260/230 > 1·91), by their buoyant densities at equilibrium in solutions of caesium chloride (one peak only at 1·702), by their RNA contents (usually < 1·5 per cent) and by their protein contents (< 2 per cent). The specific activity of the DNA was measured by combusting the weighed TCA precipitate as before.

The experiments show that (1) carcinogenic hydrocarbons bind to mouse skin DNA even after oral administration, and (2) the binding can be reduced by pretreatment with hydroxyurea. At a first glance the reduction does not seem to be too overwhelming. Considering the fact that only 1–2 per cent of the total population of skin cells are engaged in active DNA synthesis[9,10], however it can be anticipated that only this small number of cells would respond to the inhibitory action of hydroxyurea. On this basis, the relative binding of carcinogenic hydrocarbons both to replicating and resting DNA can be determined. Assuming a tritium index of 1·5 per cent and 6 h for the *S*-phase, it can be calculated that during the 4 h of the BP experiment approximately 1 per cent (1·5 × 0·66) of the epidermal DNA had been replicated. Because 57 per cent of BP-binding is sensitive to hydroxyurea or dependent on DNA-synthesis, the ratio of hydroxyurea-sensitive to hydroxyurea-insensitive bindings per cell amounts to (57/1 : 43/99 =) 131. This ratio means that BP selectively binds to replicating DNA of mouse skin with an error of less than 1 per cent. Similarly, for DMBA we found a ratio of 45.

Table 1. EFFECT OF HYDROXYUREA (0·5 MG/G MOUSE) ON THE BINDING OF CARCINOGENIC POLYCYCLIC HYDROCARBONS TO MOUSE SKIN DNA

Hydrocarbon	Hydroxyurea	D.p.m./mg of DNA	Percentage inhibition
3,4-Benzpyrene-^{3}H	+	489 ± 11	57·4
	–	852 ± 38	
7,12-Dimethylbenz(a)anthracene-^{3}H	+	256 ± 8	31·0
	–	371 ± 56	

Standard errors of the mean are indicated (four experiments).

It is not certain, of course, whether replicating DNA is itself a preferential target for carcinogenic hydrocarbons, or whether these hydrocarbons first bind to DNA precursors which fail to be incorporated into DNA under the influence of hydroxyurea. Whatever the reason for the reduced binding of BP or DMBA to DNA, this manipulation of binding may provide a tool for deciding whether the complex of DNA and hydrocarbon, as Brookes[11] postulates, or protein binding, as Heidelberger[12] claims, is essential for tumour induction. If the tumour yield is unaffected by blocking DNA synthesis (simultaneously reducing binding to DNA), it might be safe to conclude that this binding reaction is not necessary for the initiation process. If, however, the contrary were true, this would support the idea that the initiation process is somehow correlated with DNA synthesis, as suggested by other results[13,14]. Similar ideas are now being tested for rat hepatoma induced by diethylnitrosamine (personal communication from M. F. Rajewsky,)

Mice and materials were supplied by Professor E. Hecker.

BIOCHEMISTRY

Association of Acid Mucopolysaccharides with Isolated Amyloid Fibrils

IN a review of amyloidosis, Cohen[1] concludes that "mucopolysaccharide does not constitute a significant portion of the material. Several reports in the literature indicate that an unusual mucopolysaccharide containing heparitin sulphate may be present in amyloid. To date these studies have been on whole amyloid tissues, not on isolated fibrils". Experiments now in progress on the nature of acid mucopolysaccharides associated with isolated amyloid fibrils are reported here.

Samples of liver and spleen obtained at autopsy from six cases of secondary amyloidosis (confirmed by thioflavine *T* staining at *p*H 1·0) (ref. 2) and twenty normal controls were stored at −20° C until required. Fibrils were isolated using the method of Cohen and Calkins[3] and the final top layer further purified by centrifugation at 18,000*g* for 1 h in 60 per cent sucrose, the deposit being retained and the process repeated three times. The final deposit was resuspended in 0·9 per cent saline, dialysed against distilled water for 48 h and lyophilized. All these procedures were carried out at 4° C. A further sample of fibrils isolated by the same method was kindly provided by R. B. Nichols of the University of Bristol (sample *A2*—Nichols and Clamp[4]). The fibrillar nature of the isolated material was confirmed by electron microscopy.

Mucopolysaccharides were isolated from whole tissues and fibrils after digestion with papain, separated by electrophoresis on cellulose acetate membrane and identified by methods described by Manley[5]. Samples of chondroitin sulphate and hyaluronic acid and mucopolysaccharides isolated from human aorta were used as markers.

The sialic acid content of papain digests of a known weight of isolated fibrils was determined by the method of Warren[6] after hydrolysis in 0·1 N sulphuric acid for 1 h at 80° C. Uronic acid was determined by the modified carbazole method of Bitter and Muir[7] before and after dialysis in heated viscose tubing. The optical density of the reaction mixture without addition of carbazole was used as a blank. There was no significant difference between results before and after dialysis. These estimations were also made on the supernatants of control samples of amyloid fibrils incubated in the digestion mixture without the addition of the enzyme.

Non-amyloid control tissues contained a large chondroitin sulphate fraction—less than 5 per cent of which was resistant to hyaluronidase—and a small amount of hyaluronic acid. Amyloid tissues showed three fractions: a small hyaluronic acid fraction; a chondroitin sulphate fraction, a variable portion of which was resistant to hyaluronidase; and a prominent heparan sulphate fraction representing 22–73 per cent of the total material. Tissues without histological evidence of amyloid but taken from patients with positive histology in other organs had the same pattern as normal controls. These results are shown in Table 1.

Results of analyses of isolated fibrils are shown in Table 2. All the fibrils examined contained a small amount of uronic and sialic acids. No uronic or sialic acid was found in the supernatants of non-papain-digested control fibrils and hyaluronic acid was not found in any of the samples tested. A chondroitin sulphate fraction was present in all the samples but showed marked variation in sensitivity to hyaluronidase. There was a prominent heparan sulphate band in five of the seven samples examined, and it was the predominant fraction in four of them. Although the pattern varied, it is important that it is essentially the same in fibrils isolated from different tissues in the same patient (case 4).

Heparan sulphate has been isolated from whole amyloid tissues in increased amounts[8-10] and recent histochemical studies[11,12] suggest that it is the principal acid mucopolysaccharide present in amyloid deposits, associated with chondroitin sulphate and some material containing sialic acid.

The results presented here confirm the increase in heparan sulphate in whole tissues and demonstrate its association with some isolated fibrils. Hyaluronidase digestion alone must be regarded as unsatisfactory for examining the chondroitin sulphate fraction, so the possibility that this fraction may include the second type of heparan sulphate found in whole amyloid tissues[10] must be considered. Further chemical characterization of the fractions isolated is in progress.

Table 1. RESULTS ON WHOLE TISSUES

Spleen	6	0·217	0·964	100	—	—	< 5
Liver	*A*2	0·388	0·505	19	81	—	< 5

Mean uronic acid, 0·275 per cent ±0·075; mean sialic acid = 0·613 per cent ±0·168.

Two glycoproteins with carbohydrate—predominantly neutral hexose in one and sialic acid in the other—have been isolated from fibrils (case 4 liver and *A*2) examined in this study[4]. Thus although the sialic acid content of isolated fibrils is low, it reflects the presence of an important moiety. The mean sialic and uronic acid contents of the fibrils examined here are similar to the figures of 0·56 and 0·34 per cent, respectively, given by Cohen[13] and it would not be surprising if the low uronic acid content also reflects the presence of an important moiety in the amyloid fibrils.

It is difficult to assess the extent to which isolated fibrils may be contaminated by loosely bound ground substance materials, but attempts to purify them further result in a higher, rather than lower, uronic acid content[13]. The present work shows that the uronic acid reflects the presence of material which must be very firmly bound to the isolated fibril to survive repeated washings in the extraction procedures used, a conclusion supported by the fact that none of this material could be isolated without enzymatic digestion. Acid mucopolysaccharides thus constitute a small but significant and integral part of the amyloid fibril.

I thank Dr A. H. T. Robb-Smith, Radcliffe Infirmary, Oxford, in whose department this work was initiated, and Dr G. K. McGowan, in whose department it is being continued, for their interest and encouragement. R. B. Nichols and Dr G. Manley kindly provided material used in this study.

Biliprotein from the Ova of a Key-hole Limpet

THE mature ova of some limpets and key-hole limpets are green in colour[1]. In an attempt to identify the pigment responsible for the green colour of the ripe ova of the key-hole limpet *Diodora graeca* we have isolated from the ova a blue chromoprotein, which has a bile pigment as prosthetic group.

The key-hole limpets were collected in Malta from October to December, and ripe ovaries were dissected and weighed: 150–200 animals were found to give about 5 g of tissue. The material was homogenized with distilled water (250 ml.) and crushed ice (250 g) in a Waring blender. Octyl phenoxy polyethoxyethanol ('Triton *X*-100') (1 ml.) was added and the homogenate was stirred for 1 h and left at 4° C for 18 h. The homogenate was then centrifuged at 5,000*g* at 4° C for 1 h. The green precipitate was washed once in the centrifuge with distilled water (100 ml.). It was then dispersed in distilled water (100 ml.), tricalcium phosphate gel[2] (25 g) was added, and the mixture was stirred and centrifuged. The calcium phosphate was then washed with 0·1 M phosphate buffer, *p*H 7·0 (100 ml.), and subsequently with 0·1 M phosphate buffer, *p*H 7·0, containing 1 M sodium chloride (2 × 100 ml.), which gave a blue eluate. This eluate was half-saturated with ammonium sulphate, and the blue precipitate was collected by centrifuging at 5,000*g* at 4° C for 1 h. The precipitate was then dissolved in the desired buffer and dialysed against the same buffer at 4° C. Some protein which precipitated during dialysis was removed by centrifuging.

The blue protein solution showed a single component which migrated towards the cathode on cellulose acetate membrane electrophoresis with 0·1 M phosphate buffer, *p*H 7·0. Gel-filtration through a 50 × 2·5 cm column of 'Sephadex *G*-200' equilibrated with 0·05 M *tris* hydrochloric acid, *p*H 7·5, containing 0·1 M potassium chloride[3] indicated a molecular weight of 300,000 for the protein.

The prosthetic group was isolated as follows. A blue precipitate was obtained on dialysis of a solution of the protein in 0·1 M phosphate buffer, *p*H 7·0, against distilled water. The precipitate was collected by centrifuging and extracted with methanol at room temperature. The extract was evaporated to dryness in a current of air. The blue residue was soluble in chloroform as well as methanol. Thin-layer chromatography on silica gel *G* showed a single component with an average R_F of 0·6 in each of the following solvent systems: *iso*-propanol–concentrated ammonia–water (10 : 0·5 : 1, v/v); *n*-butanol–acetic acid–water (12 : 3 : 5, v/v); and chloroform–methanol–acetic acid (15 : 4 : 1, v/v).

The prosthetic group was identified as a bile pigment because it gave a positive Gmelin reaction; a solution of the pigment in aqueous methanol turned violet, then red, and finally colourless after the addition of concentrated nitric acid.

The absorption spectrum of the pigment in 5 per cent (w/v) methanolic hydrochloric acid showed maxima at 615, 396 and 325 mμ and inflexions at 420, 365 and 270 mμ. The zinc complex salt of the pigment showed maxima at 610 and 405 mμ in chloroform solution, and exhibited weak green fluorescence in ultraviolet light. On oxidation with iodine in the presence of ammonia, it showed maxima at 610, 515 and 365 mμ and an inflexion at 405 mμ.

The pigment seems to be a bilidiene in view of its blue colour, absorption spectrum, reaction with nitric acid, and formation of a zinc complex with fluorescence in ultraviolet light.

Effect of Orotic Acid on Activity of Nuclear DNA-dependent RNA Polymerase and Polyribosomal Profiles in Deficient Chick Liver lacking Vitamin B_{12}

Orotic acid, like vitamin B_{12}, increases the RNA[1] and free nucleotides[2] in the liver of chicks deficient in vitamin B_{12} and stimulates the incorporation of phosphate labelled with phosphorus-32 into these structures[3]. More recently, a significant increase in the incorporation of ^3H-formate into RNA of subcellular fractions of liver and into acid-soluble free nucleotides has been found in chicks treated with orotic acid[4].

This communication concerns a comparison of the effect of orotic acid and vitamin B_{12} on the activity of nuclear DNA-dependent RNA polymerase and on polyribosomal profiles in chick livers deficient in vitamin B_{12}.

We have investigated the part played by orotic acid in the metabolism of nucleic acid. Orotic acid is a growth factor for chicks and rats which are fed on a diet deficient in vitamin B_{12}[5,6].

One day old New Hampshire × White Leghorn chicks were divided into three groups. One group received a diet deficient in vitamin B_{12}[7], the other two groups received the same diet supplemented with either 10 μg of vitamin B_{12} or 10 mg of orotic acid in every 100 g of diet. After 5 weeks, six chicks from each group were injected with sodium ^3H-formate in a sterile solution (50 μCi/100 g body weight). The chicks were killed 2 h later and the livers were quickly removed. Ribosomes were obtained from the mitochondria-free supernatant of a whole liver homogenate treated with bentonite[8], and were treated with sodium deoxycholate (final concentration 1·3 per cent w/v). Ribosomes suspended in a medium according to Tata and Widnell[9] were layered over a 15–30 per cent w/v linear sucrose density gradient. After centrifuging for 3 h at 63,000*g*, 0·5 ml. fractions were collected; extinction was measured at 260 mμ and radioactivity was determined by adding scintillator fluid[10] in a Nuclear Chicago automatic spectrometer. Sedimentation coefficients were calculated[11,12].

Table 1. EFFECT OF OROTIC ACID AND VITAMIN B_{12} ON DNA-DEPENDENT RNA POLYMERASE ACTIVITY IN VITAMIN B_{12}-DEFICIENT CHICK LIVER

Group	Animals in experiment	RNA polymerase activity (percentage of control) Activated by Mg^2	Activated by $Mn^{2+}/(NH_4)_2SO_4^-$
1	Vitamin B_{12}-deficient (control)	100	100
2	Orotic acid-treated	131	261
3	Vitamin B_{12}-treated	107	271

Results are the averages of three determinations of pooled livers (three livers per pool). Duplicate experiments agreed within ±10 per cent. Magnesium-activated RNA polymerase activity in the control was 148 μμmoles of ^{14}C-AMP incorporated/15 min/mg of DNA. Manganese-activated RNA polymerase activity in the control was 98 μμmoles of ^{14}C-AMP incorporated/45 min/mg of DNA.

RNA polymerase activity, dependent on nuclear DNA, was assayed in liver of other animals from the same experimental groups. Both the reactions which are dependent on magnesium and those dependent of manganese and ammonium sulphate were assayed by measuring the incorporation of ^{14}C-AMP into the acid-insoluble RNA[9]. The radioactivity of samples labelled with carbon-14 dissolved in formic acid was measured by adding ethyleneglycol monomethylether and the liquid scintillator[10].

Profiles of the sedimentation of polyribosomes from chicks treated with orotic acid (Fig. 1, graph 2) as well as from those treated with vitamin B_{12} (Fig. 1, graph 3) show higher radioactivities in the peaks *d*, *e* and *f*, which correspond to 206 *S*, 259 *S*, and 280 *S* polyribosomal aggregates, respectively, when compared with the profile of chicks deficient in vitamin B_{12} (Fig. 1, graph 1).

The results for the activity of DNA-dependent RNA polymerase show that the reaction activated by manganese and ammonium sulphate is significantly increased in

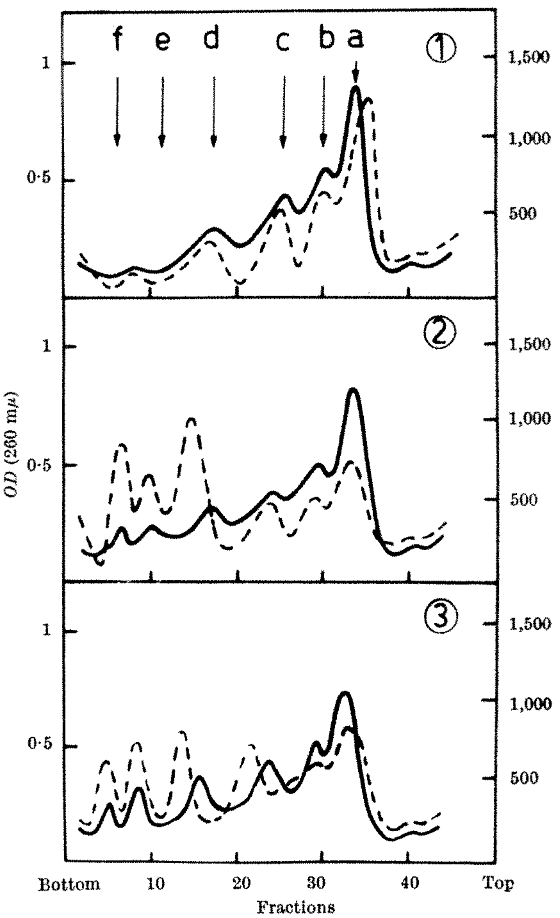

Fig. 1. Effect of orotic acid and vitamin B_{12} on profiles of polyribosomal sedimentation chick liver deficient in vitamin B_{12}; Graph 1, vitamin B_{12}-deficient; graph 2, treated with orotic acid; graph 3, treated with vitamin B_{12}; (peak *a* = 73 *S*; *b* = 113 *S*; *c* = 147 *S*; *d* = 206 *S*; *e* = 259 *S*; *f* = 280 *S*). ———, Optical density at 260 mμ; - - - -, radioactivity.

the liver of chicks treated with orotic acid or vitamin B_{12}, while no changes are found in the reaction activated by magnesium. The higher optical density and radioactivity of the regions corresponding to the polyribosomal aggregates of 5, 7 and 8 repeating units indicate a positive effect of orotic acid not only on the ability of ribosomes to be aggregated, but also on the levels of rapidly labelled cytoplasmic RNA. This is in agreement with the increased manganese/ammonium sulphate-activated RNA polymerase activity, observed in the orotic acid-treated chicks. According to Widnell and Tata[13], the product of the reaction activated by manganese and ammonium sulphate represents (in terms of base composition and nearest-neighbour frequency) a more DNA-like RNA, whereas that of the reaction activated by magnesium is a ribosomal type of RNA.

These results lead us to suggest that orotic acid has a positive effect on the biosynthesis of *m*RNA.

Polyoma Virus-induced Release of Inhibition of Cellular DNA Synthesis caused by Iododeoxyuridine

THE halogenated pyrimidine nucleosides, 5-iodo-2′-deoxyuridine (IUdR) and 5-bromo-2′-deoxyuridine (BUdR), are incorporated instead of thymidine into the DNA of mammalian cells for one division cycle. The synthesis of DNA is then delayed and takes place only in a small fraction of the cells[1]. At high concentrations of these compounds (or at low concentrations when 5-fluoro-2′-deoxyuridine (FUdR) or amethopterin is present and inhibits endogenous synthesis of thymidine) the DNA doubles once; no further increase in the DNA content of the cultures is observed, even after the analogues have been removed[2,3].

The mechanism of inhibition of DNA synthesis by the halogenated pyrimidine nucleosides has been attributed to either (1) a malfunction of the IUdR-containing genes involved in the regulation of DNA synthesis, or (2) the presence of IUdR at special sites in the DNA which results in steric hindrance and prevents the replication of DNA[1-5]. The experiments described here were an attempt to differentiate between these possibilities.

Infection with polyoma virus of cells in stationary phase, or of X-irradiated cells that have lost their ability to synthesize DNA, results in the resumption of cellular DNA synthesis[6-8]. Cells that have been treated with IUdR before infection can support the growth of polyoma virus[9], and so it was interesting to determine whether such cells would also regain their ability to synthesize cellular DNA.

Primary mouse embryo (ME) cells grown in Eagle's medium[10] containing 3 per cent dialysed serum (EDS) were infected with the small plaque variant of polyoma virus[11] (multiplicity of infection, approximately 20 PFU/cell). The determination of the incorporation of ^{14}C- or ^{3}H-adenine, ^{3}H-deoxycytidine, and ^{14}C-thymidine or ^{3}H-thymidine into DNA, as well as the extraction and isopycnic centrifugation in caesium chloride of DNA, have been described before[12]. Cellular DNA was separated from viral DNA on methylated–albuminin–kieselguhr columns (MAK), also as described before[13].

We determined first the degree of incorporation of IUdR into the DNA of mouse embryo cultures and whether these cultures are able to resume DNA synthesis after removal of the analogue. One day after seeding, the cultures (containing approximately $1·5 \times 10^6$ cells/90 mm Petri dish) were incubated in EDS with FUdR (2 μg/ml.) and IUdR (20 μg/ml.) for 3 days with daily changes of medium. Cultures treated identically but which were supplied with thymidine (20 μg/ml.) instead of IUdR served as controls. The degree of replacement of IUdR for thymidine in the DNA of the IUdR-treated cultures was ascertained from the buoyant density of the DNA in caesium chloride in the Spinco Model *E* analytical centrifuge, as described before[14]. Two peaks of DNA appeared: one of these peaks, containing approximately one third of the DNA in the sample, consisted of normal thymidine-containing DNA ($\rho = 1·701$ g/cm^3); the second peak had a buoyant density of 1·757 g/cm^3 and consisted of hybrid DNA composed of one strand of normal, thymidine-DNA and one in which about 95 per cent of the thymidine has been replaced by IUdR. The presence of normal thymidine-containing DNA in the sample indicates that not all the DNA of the cells in the culture replicated during the period of incubation with IUdR.

Table 1. EFFECT OF TREATMENT WITH IUdR BEFORE INFECTION ON DNA SYNTHESIS IN POLYOMA VIRUS-INFECTED AND UNINFECTED CELLS

	IUdR	Thymidine
	(c.p.m./sample)	
Uninfected	1,520	7,100
Infected	10,900	14,291

Cultures treated with IUdR, as described before, were washed extensively and were infected with polyoma virus. Twenty-four hours later, ^{3}H-thymidine (0·5 μCi/ml.; specific activity, 416 mCi/mM) was added for 1 h. The cultures were collected and the amount of the label in the DNA was determined. Table 1 shows that incorporation of thymidine into DNA was reduced in non-infected cultures by about 80 per cent after treatment with IUdR. The infected IUdR-treated cultures synthesized, however, only 23 per cent less DNA than the infected cultures treated with thymidine. Similar results were obtained when the incorporation of ^{3}H-adenine into DNA was tested. The type of DNA (viral or cellular) synthesized by the infected IUdR-treated and thymidine-treated cultures was determined. In both cases, approximately 85 per cent of the label was found in cellular DNA as indicated by its elution pattern from MAK columns. Thus cultures which have incorporated IUdR into DNA regain the ability to synthesize cellular DNA after infection with polyoma virus. The cultures treated with IUdR, however, contained cells that had not replicated in the presence of IUdR, shown by the fact that a fraction of the DNA of these cultures consisted of normal DNA containing thymidine, and it was therefore necessary to determine whether DNA molecules containing IUdR had actually replicated after infection. One day after seeding, mouse embryo cultures were incubated for 8 h with ^{14}C-thymidine (0·06 μCi/ml., specific activity, 31 mCi/mM). The label was removed and the cultures were incubated for 3 days with IUdR and FUdR, as already described. (At the end of this incubation period, DNA labelled with carbon-14 and with two different buoyant densities was present in the cultures. Of the radioactivity, 34 per cent was associated with normal thymidine-DNA and the rest with hybrid IUdR-DNA.) The cultures were washed extensively to remove IUdR, infected with polyoma virus, and incubated with unlabelled thymidine and ^{3}H-adenine for 48 h. IUdR had been removed from the medium before the addition of ^{3}H-adenine, and so this label would become associated with IUdR-hybrid DNA only if the molecules of hybrid IUdR-DNA present in the cultures at the time of infection were to replicate.

Table 2. REPLICATION OF IUdR-HYBRID DNA IN POLYOMA VIRUS-INFECTED AND UNINFECTED CELLS

	Tritium label in DNA			
	Infected		Uninfected	
	c.p.m./ sample	Percentage of total	c.p.m./ sample	Percentage of total
Thymidine DNA	28,354		9,365	
IUdR-hybrid DNA	15,943	37·6	1,136	10·7
Incorporation resulting from IUdR-hybrid DNA replication	31,886	75·2	2,272	21·5

Infected and uninfected cultures treated with IUdR before infection were incubated for 48 h in EDS containing thymidine (10 μg/ml.) and ^{3}H-adenine (1 μCi/ml.; specific activity, 7 mCi/mM). The DNA extracted from the cultures was subjected to equilibrium sedimentation in caesium chloride and the amount of tritium associated with the peaks of DNA was determined. Of the total ^{3}H-adenine in the DNA of the infected cells 5 per cent was in viral DNA (as determined by its ability to renature after heat denaturation). Viral DNA will consist of thymidine DNA, and so 5 per cent of the total counts in the sample was subtracted from the thymidine DNA before tabulation.

Table 2 shows the distribution of tritium in the peaks of hybrid-IUdR and normal thymidine DNA obtained from infected and uninfected cultures. In the uninfected cells, approximately 11 per cent of the label was associated with IUdR-hybrid DNA, and because the replication of a hybrid DNA molecule in the conditions described will give rise to one ^{3}H-thymidine-IUdR molecule and one ^{3}H-thymidine–thymidine molecule, 22 per cent of the total radioactivity incorporated into DNA was due to the replication of hybrid IUdR-DNA. The relative frequency at which the IUdR-hybrid DNA molecules replicated was thus considerably reduced as compared with the molecules containing thymidine, for 66 per cent of the DNA in the cultures was IUdR-hybrid DNA and only 22 per cent of the incorporation of label into DNA in the cultures resulted from the replication of this DNA. These results differ somewhat from those of Morris and Cramer[15,16], who found that half of the IUdR-containing molecules can replicate after removal of IUdR from the cultures.

The proportion of IUdR-hybrid DNA molecules that replicated was increased after infection of the cultures with polyoma virus (Table 2). Approximately 75 per cent of the incorporation into DNA was calculated to be caused by the replication of hybrid IUdR-DNA; this DNA comprised 66 per cent of the DNA in the culture, and infection with polyoma virus thus seems to have resulted in the complete resumption of the ability of IUdR-hybrid molecules to replicate.

We next tested whether hybrid IUdR-containing molecules would also replicate after infection when IUdR was not removed from the cultures, and whether DNA with IUdR in both strands would thus be synthesized. An experiment essentially analogous to the one already described was performed. Mouse embryo cells were incubated with FUdR (2 μg/ml.), IUdR (20 μg/ml.) and ^{3}H-deoxycytidine (2 μCi/ml.; specific activity, 1·25 Ci/mM) for 3 days. At the end of this incubation period, only DNA with a density corresponding to hybrid IUdR-DNA had become labelled. The cultures were washed, infected with polyoma virus, and incubated with FUdR (2 μg/ml.), IUdR (20 μg/ml.), deoxycytidine (10 μg/ml.) and ^{14}C-adenine (0·04 μCi/ml.; specific activity, 55 mCi/mM) for 48 h. The cells were collected and DNA was extracted and subjected to isopycnic centrifugation in caesium chloride. Fig. 1 shows that all the ^{14}C-adenine incorporated into the DNA of uninfected cultures banded in a position characteristic of hybrid IUdR-DNA, and that no DNA molecules with IUdR in both strands were formed. In the infected cultures, however, about 30 per cent of the carbon-14 was present in DNA that banded in a position characteristic of double-stranded IUdR-DNA. This DNA consisted, at least partially, of cellular DNA, for tritiated DNA that had been present in the cells at the time of infection shifted to the position of double-stranded IUdR-DNA. (Cellular DNA is not degraded into an acid-soluble form after infection.) These experiments show clearly that whereas in uninfected cultures DNA synthesis is inhibited in most of the cells that have incorporated IUdR into one strand of this DNA, this inhibition is reversed after infection with polyoma virus.

Cellular DNA synthesis is renewed after infection of cells in which IUdR has been substituted for thymidine in one strand of DNA, and so the inhibitory effect of IUdR is probably not a result of its presence *per se* in the DNA and a consequent physical hindrance of replication. This renewal, however, may be caused by the synthesis in the infected cells of a DNA polymerase which, in contrast to the polymerase present in uninfected cells, is able to use IUdR-hybrid DNA as a template. The renewal of DNA synthesis may reflect also the fact that the incoming viral genome carries the information for the formation of proteins (enzymes or regulatory proteins) necessary for the replication of cellular DNA, these proteins not being functional when coded by DNA which contains IUdR. On the other hand, the regulatory mechanisms normally controlling cellular DNA synthesis may not be operative in cells infected with polyoma virus.

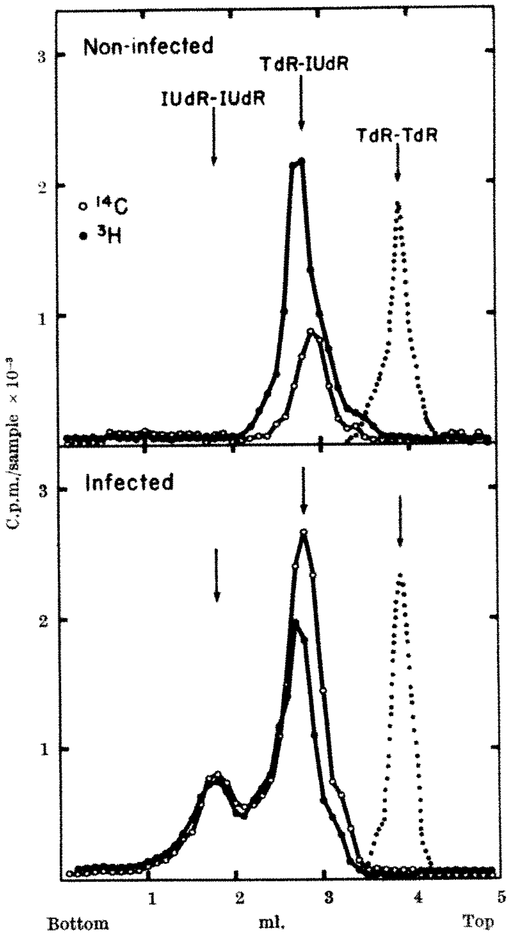

Fig. 1. Formation in cells infected with polyoma virus of cellular DNA containing IUdR in both strands. See text for experimental details. TdR, thymidine.

L-Asparaginase Activity in Human and Animal Sera

AN outstanding characteristic of the amino-acid enzyme L-asparaginase is its ability to inhibit the growth of certain rodent leukaemias[1-3]. This was established by Broome[4], who followed up the observation by Kidd[5] that administration of guinea-pig serum inhibited the growth of the Gardner lymphosarcoma (tumour *6C3HED*) in *C3H* mice. L-Asparaginase can be extracted not only from guinea-pig serum but also from certain types of *Escherichia coli*[6,7].

Administration of preparations of *Escherichia coli* asparaginase to three dogs with lymphosarcoma produced remission in each[8,9]. A child with lymphoblastic leukaemia, resistant to conventional therapies, was given an extract of asparaginase from guinea-pig serum[10]; this caused amelioration of the leukaemic process, but it also caused severe side-effects. Three patients with acute leukaemia treated by Hill *et al.*[11] with an *Escherichia coli* asparaginase showed no immediate toxic effects, however, and there were definite signs of a favourable response. Further therapeutic evaluation of this material is limited by the difficulty in obtaining sufficient quantities of it.

Asparaginase activity can be determined by measuring the ammonia liberated in the transamination and hydrolysis of asparagine[12]. Precipitation by ammonium sulphate increases the specific activity of asparaginase from guinea-pig serum, but the more purified preparations have shown a decrease in biological activity[13]. L-Asparaginase from *E. coli* exists in two forms[14] with widely differing biological activities[15,16].

We have measured asparaginase activity by the method of Meister[17], the liberated ammonia being determined by treatment of the protein-free supernatant with Nessler's reagent. The units of asparaginase activity are defined as the number of μmoles of ammonia liberated at the maximum rate from 1 ml. of test solution in 1 h in the conditions of the reaction.

L-Asparaginase activity was not detected in any of twenty-five human sera from control subjects. Similarly, sera from a variety of animal species (horse, cow, pig, sheep, dog, monkey, rabbit and hen) were also assayed and in none of these was any activity found. Holmquist[18] found similar results with four human sera. We further tested the effect of the addition of various sera on the asparaginase activity of guinea-pig sera and coliform extracts (Worthington Biochemicals), having established that dilution of these with borate buffer did not influence the recovery of the enzyme. The test system consisted, of two aliquots of solution containing asparaginasee diluted with either borate buffer (x') or the serum to be tested (x). After thorough mixing, samples were taken into the buffered incubation medium for asparaginase assay.

Table 1. UNITS OF ASPARAGINASE ASSAYED IN GUINEA-PIG SERA IN BUFFER (x') AND AFTER THE ADDITION OF HUMAN SERUM (x)

Units assayed after addition of borate buffer (x')	Units assayed after addition of serum (x)	$\frac{x-x'}{x'}$ (per cent)

Pig	1	113·7	132·1	17·0

All human sera which were tested enhanced the asparaginase activity of the guinea-pig sera by 6 per cent to 23 per cent and the degree of enhancement did not correspond to the initial asparaginase content (Table 1). Of the animal sera tested, all except the sheep and pig gave clearly negative results (Table 2). Sera from four pigs were assayed and only one, tested on three occasions, showed any enhancement; sheep serum consistently enhanced the asparaginase activity of guinea-pig serum.

With the coliform extract the pattern of results is different, in that the addition of all human and animal sera gave enhanced activity (Tables 3 and 4).

We concentrated the protein fraction from human serum by ultrafiltration through a collodion membrane over an ice bath and tested both the protein concentrate and the filtrate containing the soluble salts and amino-acids, for their effect on the assay of asparaginase from guinea-pig serum. The asparaginase enhancing effect was contained in the protein moiety, the protein-free fraction having no such effect.

Experiments are to be undertaken to define further the serum factors responsible for the enhancement of asparaginase activity and to attempt to determine whether this has any biological counterpart.

This work was supported by the Northern Ireland Leukaemia Research Fund. We thank Dr M. G. Nelson and Mr D. W. Neill for their interest and advice, and Miss C. D. Bolger and Miss R. M. Niblock for technical assistance.

GENETICS

Albumin Máku: a New Variant of Human Serum Albumin

AT least six different electrophoretic variants of human serum albumin have been found in man; three migrate more rapidly than normal and three less rapidly[1,2]. One of these, a rapidly migrating variant, occurs at a frequency of 5–30 per cent in several tribes of North American Indians[3]. As one aspect of a multidisciplinary study of the Yanomama Indians of southern Venezuela and adjacent parts of Brazil[4], sera from 1,111 individuals residing in twenty-five villages were examined for albumin type. Although no example of the rapidly migrating variant which is common in North American Indians was observed, we did note, when testing 75 of 108 persons residing at the village of Borabuk (2° 45′ N. and 62° 05′ W.), four individuals who possess a variant which also migrates more rapidly towards the anode in starch gel electrophoresis than does normal albumin.

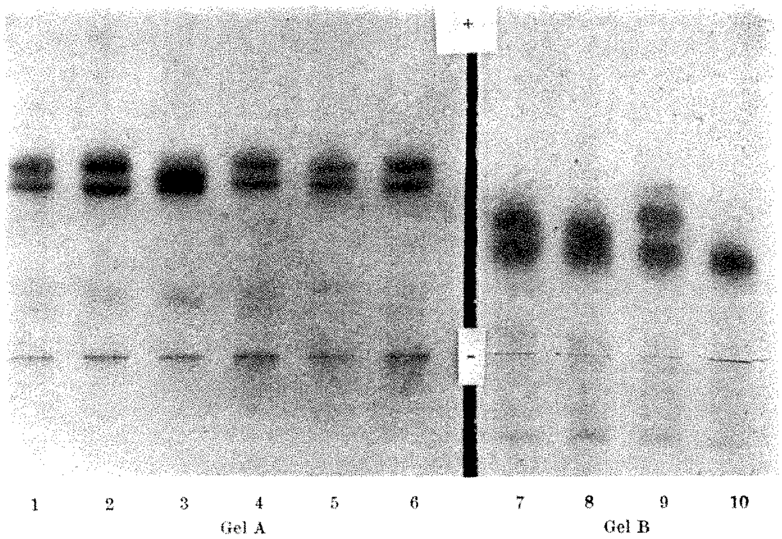

Fig. 1. Albumin Máku. Comparative vertical starch gel electrophoresis using the three types of rapidly migrating albumin variants and slight modifications of the electrophoretic conditions detailed in Weitkamp *et al.*[1]. Gel A: Electrophoresis for 5 h in the *tris*-EDTA-borate system, *p*H 6·9 (starch hydrolysed, Lot 245–1, Connaught Laboratories, Toronto) Gel B: Electrophoresis for 19 h in the acetate-EDTA system, *p*H 5·0 (Lot 174, Electrostarch Co., Madison, Wisconsin). Positions 1, 4, 6, 8: Albumin Máku; 2, 9: "very fast"; 3: "fast"; 5, 7: "faster".

The fact that this variant is different from the three previously described types of rapidly migrating albumin variants[1] can be seen in the photograph of two starch gel electropherograms in Fig. 1. The new variant clearly migrates more rapidly than the "fast" type in Gel A and more slowly than the "very fast" type in Gel B. The "faster" type of variant, which is polymorphic in North American Indians, migrates less rapidly compared with the new variant in Gel A and more rapidly compared with the new variant in Gel B.

The four individuals who are heterozygous for normal and variant albumin are related as indicated in the pedigree in Fig. 2. Three of five possible mates of I-1 and

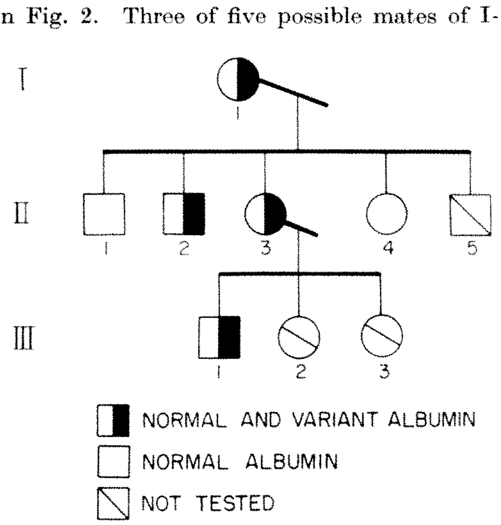

Fig. 2. Pedigree of the family from Borabuk showing albumin phenotypes. Three of five possible spouses for I-1 and one of two possible spouses for II-3 were tested and demonstrated normal albumin only. (Squares designate males, circles females.)

one of two possible mates of II-3 were tested and showed normal albumin only. Although the albumin types for the other possible mates are not known, this variant, because it is uncommon in the village, is probably inherited through the individuals identified in the pedigree. All of the individuals heterozygous at the albumin locus are homozygous at the *Gc* locus; consequently, the family does not provide an opportunity to test the possibility of close autosomal linkage between loci for serum albumin and *Gc* protein which has been described in families segregating for other albumin variants[2,5,6].

The new albumin variant was introduced into the Yanomama village of Borabuk by individual I-1 (Fig. 2), a woman captured from the Máku tribe[7] in a raid some time during the early 1930s. In 1925 the Máku were still a viable cultural entity, maintaining settlements of their own on the Rio Uraricoera[8]. During an eastward expansion by the Yanomama, however, the Máku were reduced to virtual extinction: by 1964 only three individuals were known to be able to speak the Máku language[9]. Although a number of Máku may have been incorporated into a second Yanomama group on the Rio Uraricaá[9], there seem to be few individuals who have survived to reproduce within Yanomama society. The woman who did survive, however, was not subjected to the traditional Yanomama customs relating to marriage and reproduction because she was an outsider[10]. She provided several men in the village with an opportunity to reproduce earlier in their lives—men who might otherwise not have obtained a spouse until later, or perhaps not at all. She was, in turn, provided with reproductive opportunity which was somewhat better than usual, as witnessed by the fact that she has five surviving children (compared with an average of 3·2 for post-menopausal Yanomama women)[11]. The probability of retention of the new gene which this woman introduced into the village may therefore have been partly determined by cultural factors affecting her reproductive behaviour.

The new albumin variant, apparently foreign to the Yanomama population, was introduced by a captive member from the nearly extinct Máku tribe. In consideration of this once numerous and culturally significant but now dying people, we propose to name the new variant Albumin Máku, at least until a proper name which identifies the structural alteration in the variant can be assigned.

We thank Professor James V. Neel for his criticism of the manuscript and help in the project, and Mrs K. Ryan for technical assistance. This work was supported by a US Atomic Energy Commission contract.

BIOLOGY

Discrimination between Heavy Water and Water by the Mouse

THE experiment described here indicates that mice are able to discriminate between D_2O and H_2O. Two male litter mates of *Mus musculus domesticus* (strain *T–O*) were kept in separate Harwell type cages, each fitted with two water bottles. In the experimental cage, one bottle contained D_2O and the other glass-distilled H_2O, and in the control cage each bottle contained glass-distilled H_2O. The bottles were refilled every 24 h and the quantity taken from each during the previous day was determined. The bottles were replaced in the cages in a random manner, following Fisher and Yates's table of random numbers. The experiment was continued for 14 days and Table 1 shows the quantities of liquid taken during that period by the two mice.

Table 1

Experimental cage		Control cage	
H_2O (ml.)	D_2O (ml.)	H_2O (ml.)	H_2O (ml.)
12·8	2·8	7·2	10·2
13·2	3·2	15·2	13·4
15·2	2·1	10·0	12·0
14·2	2·1	9·5	12·0
12·2	3·6	14·4	5·0
14·0	3·6	12·0	15·0
15·2	4·2	14·6	17·4
10·8	2·0	4·4	11·0
9·6	2·4	5·0	12·2
11·4	1·0	8·0	4·0
12·0	1·2	7·2	3·2
12·6	3·4	8·0	10·2
10·2	1·8	10·0	5·2
9·5	1·4	5·2	7·4

It is clear from the results in Table 1 that *Mus musculus* can distinguish ($P \leqslant 0·001$) between H_2O and D_2O. There was no significant difference between the amounts taken from the two bottles in the control cage ($P > 0·7$).

This result is of interest in two different contexts. First, it has been proposed that the decreased fluid intake of rodents presented with D_2O or deuterated water is the result of a decrease in excretion[1]. My results suggest that distaste for D_2O may also contribute to the observed diminution in excretion. Second, Shallenberger[2] has suggested that the formation of hydrogen bonds between a molecule and a gustatory receptor site plays an important part in stimulating the receptor cell. It is known[3] that the bonds attaching deuterium to oxygen are considerably more stable than those attaching hydrogen to oxygen. The ability of D_2O and H_2O to form hydrogen bonds is thus significantly different. It is possible that the mouse uses this difference as the discriminandem between D_2O and H_2O.

Phylogenetic Relationships among Venomous Snakes of the Genus *Agkistrodon* from Asia and the North American Continent

AMONG a great number of venomous snakes, *Agkistrodon* is the only genus which is found in both Asia and the North American continent. The Asiatic members of *Agkistrodon* consist of seven species and range from Japan, Formosa, China, south-east Asia (excluding Celebes and Philippines), India, Central Asia and southern Siberia, to the borders of the Caspian Sea and the Ural River. Three species of *Agkistrodon* are distributed on the North and central American continents, and are found in the south-eastern portion of the United States, all of Mexico and most of Central America. The *Agkistrodon* of Asia and America are morphologically similar.

It has been shown by a number of investigators that the chemical properties of venoms can be used as an index for taxonomy and phylogenetic relationships[1-3]. It is therefore of interest to investigate and compare the immunological properties of venoms of morphologically similar snakes which are geographically widely separated.

For this study, venoms of *A. contortrix laticinctus* (broadbanded copperhead), *A. contortrix contortrix* (southern copperhead) and *A. piscivorus piscivorus* (eastern cottonmouth) were selected from the United States. *A. bilineatus* (tropical moccasin) from Central America, *A. halys* (mamushi) from Japan and two venoms of *A. rhodostoma* (Malayan pit viper) from Asia were also selected. Venom was extracted from *A. rhodostoma* captured in the vicinity of Bangkok, Thailand. Another sample of venom was milked from snakes captured in the northern part of Malaya.

Antibodies to *A. rhodostoma* were obtained from horses immunized with snake venoms of Thailand origin. Antibodies to *A. contortrix laticinctus* were prepared from rabbits (New Zealand White) following immunization.

Immunodiffusion was carried out at 3° C for 24 h in 1 per cent 'Difco' agar made 0·85 per cent in sodium chloride and 3·75 per cent in glycine. Immunoelectrophoresis was carried out in 1 per cent agar, in 0·0275 M barbital at *p*H 7·00. Electrophoresis was run for 3 h using 260 V and 13 A at room temperature. Diffusion was carried out for 24 h at 28° C.

Venoms were used at a concentration of 10 mg/ml. for species other than *A. rhodostoma* tested against its own antibody, in which cases 20 mg/ml. was used.

It can be seen from Fig. 1 that precipitin lines obtained from Ouchterlony double diffusion for *A. rhodostoma* of Thailand and Malayan origins fused together. Immunoelectrophoretic patterns of these two snakes were also very similar. This evidence indicates that *A. rhodostoma* of Thailand and Malayan origins are identical. Considerably different precipitin lines were observed, however, with other venoms. Venom of *A. halys* from Japan gave two lines which were considerably darker than those for venoms of North and Central American origin. The immunoelectrophoretic pattern (Fig. 2) also indicated that *A. halys* is more similar to *A. rhodostoma* than North and Central American species. The pattern of *A. bilineatus* of Central America had the least similarity to that of *A. rhodostoma*.

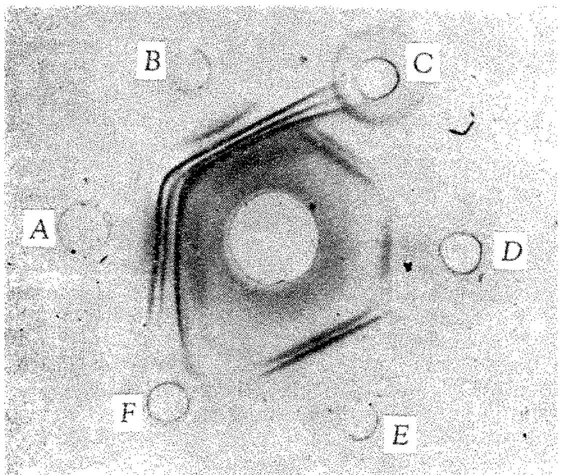

Fig. 1. Ouchterlony reaction of horse anti-*A. rhodostoma* venom of Thailand origin (centre well) against: (*A*) *A. rhodostoma* venom from Thailand; (*B*) *A. rhodostoma* venom from Malaya; (*C*) *A. contortrix contortrix* venom from North America; (*D*) *A. piscivorus piscivorus* venom from North America; (*E*) *A. halys* venom from Japan; (*F*) *A. contortrix laticinctus* venom from North America.

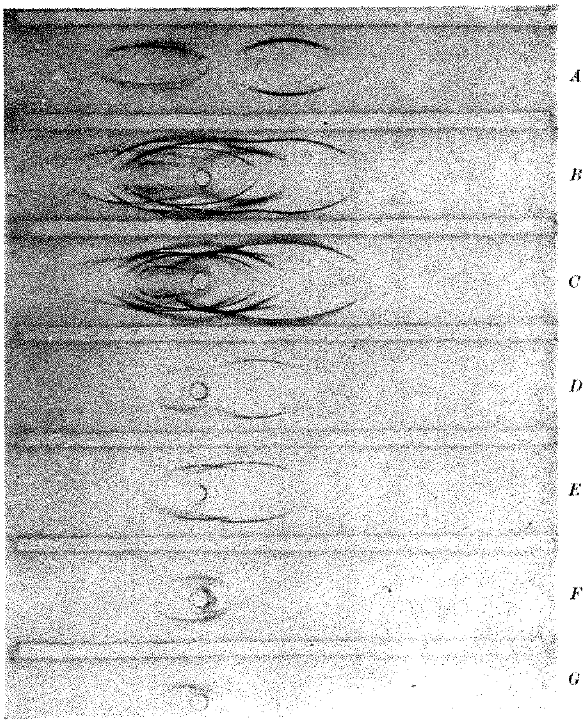

Fig. 2. Immunoelectrophoretic patterns of horse anti-*A. rhodostoma* of Thailand origin (in trough) against: (*A*) *A. halys* venom from Japan; (*B*) *A. rhodostoma* venom from Thailand; (*C*) *A. rhodostoma* venom from Malaya; (*D*) *A. contortrix laticinctus* venom from North America; (*E*) *A. contortrix contortrix* venom from North America; (*F*) *A. bilineatus* venom from Central America; (*G*) *A. piscivorus piscivorus* venom from North America.

It is of interest to note that a degree of similarity is related to geographical distance. Degree of kinship estimated from Fig. 1 and Fig. 2 is in the order *A. rhodostoma* (Thailand and Malaya), *A. halys* (Japan), three snakes from North America (*A. contortrix laticinctus*, *A. contortrix contortrix*, *A. piscivorus piscivorus*) and *A. bilineatus* (Central America).

When antibodies to *A. contortrix laticinctus* were used, immunoelectrophoretic patterns of the North American snake venoms became very similar (Fig. 3). Venom from *A. halys* of Japanese origin responded to antibodies to *A. contortrix laticinctus* more positively than venom of *A. rhodostoma* from either Thailand or Malaya. Venom from *A. bilineatus* of Central America gave sharp lines, but these were quite distinct from those of North American origin.

From these investigations, it can be concluded that in the order of the genetic kinship, *A. halys* from Japan lies between *A. rhodostoma* from south-east Asia and North American members of *Agkistrodon*. Phylogenetically, however, *A. halys* from Japan is somewhat closer to North American *Agkistrodon* than to south-east Asian *Agkistrodon*.

It is generally believed by zoologists that *Agkistrodon* of the North and Central American continent migrated from Asia when the American continent was connected to the Asiastic mainland, at the present Bering Strait area. This is also the case for many animals in North America. The Bering land bridge has been exposed or submerged to only shallow seas several times during prehistoric years; the most recent land bridge was about 12,000 yr ago[4]. Between 12,000 and 22,000 yr ago any migration of mammals was impossible because of the blockage by the western edge of the Cordilleran ice sheet[4]. Reptiles are more sensitive to cold climate than mammals. The migration of snakes to America must therefore have occurred earlier than 22,000 yr ago. Our immunological

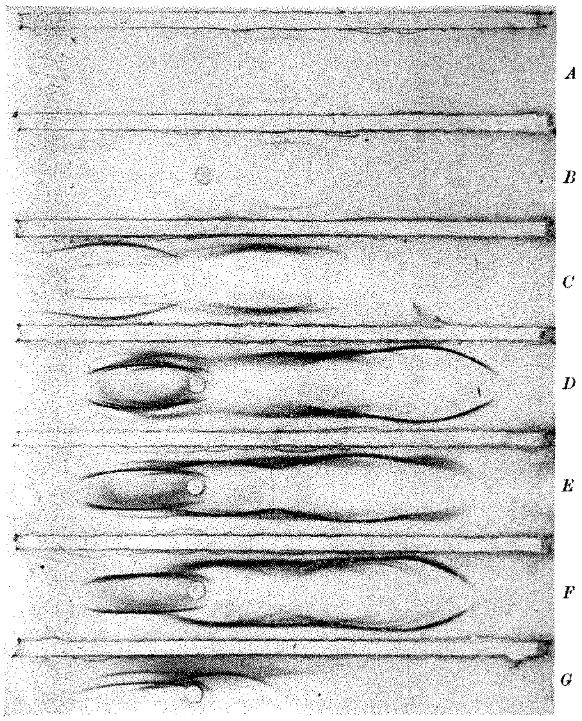

Fig. 3. Immunoelectrophoretic patterns of rabbit anti-*A. contortrix laticinctus* venom of North American origin (in trough) against: (*A*) *A. rhodostoma* venom from Thailand; (*B*) *A. rhodostoma* venom from Malaya; (*C*) *A. halys* venom from Japan; (*D*) *A. contortrix laticinctus* venom from North America; (*E*) *A. contortrix contortrix* venom from North America; (*F*) *A. piscivorus piscivorus* venom from North America; (*G*) *A. bilineatus* venom from Central America.

study indicated that differences between Asian and American snakes are considerable and it is very doubtful that such a large genetic difference could evolve in a time span of a mere 22,000 yr. It is known among geologists that Formosa was part of the Asiatic mainland some geological aeons ago; when we investigated the immunological difference of the Thailand cobra (*Naja naja siamensis*) and the Formosan cobra (*N. naja atra*), we found that the difference was very small[5].

We believe therefore that migration of snakes to America from Asia occurred much earlier than 22,000 yr ago.

This investigation was supported by US Public Health Service research grants.

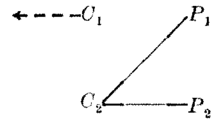
Adoptive Suckling in the Grey Seal

ALMOST all accounts of the natural history of the grey seal *Halichoerus grypus* give the impression that a cow invariably seeks and feeds only her own pup among the dozens or hundreds in a breeding colony which may be at an equivalent stage of development as her pup. Normal feeding fidelity may be represented thus

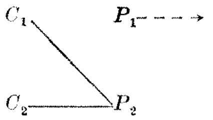
$$\begin{tikzcd} C_1 \arrow[r, dash] & P_1 \\ C_2 \arrow[r, dash] & P_2 \end{tikzcd}$$

etc.

Although there is no doubt that this is frequently the case, several patterns of adoptive feeding can and do occur both spontaneously and as a result of disturbance. Hewer and Backhouse[1] and others have reported a cow seen attending two pups, often of dissimilar size. Twins have not been recorded with certainty for this species, and so it can be assumed that one of these pups had been deserted by its mother. This can be called "foster feeding", for it replaces the normal pattern when one adult is absent temporarily or permanently, and can be represented as

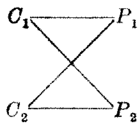


A marked feature of most grey seal breeding colonies around Great Britain is a high pup mortality which Coulson and Hickling[2] have correlated with population density according to the amount of accessible shoreline. When a proportion of the pups die within a few days of birth (lactation lasts about 18 days) some cows are left with milk, and observations have shown that the following pattern may occur



This can be called "supplementary feeding"; "fosterage" is not appropriate when the mother is still available to the second pup which feeds from both cows.

Observations have also shown that if the disappearance of a cow or a pup from the whelping ground is temporary, the following feeding pattern may occur



Both pairs of related animals remain available, neither being forced to replace a missing relative, and in this case also "fosterage" is not an appropriate term. I prefer "contingent feeding", which implies that it occurs when opportunities arise.

During extensive field studies of maternal relations in the grey seal in the Hebrides and Orkney in 1963–66 I have made the following observations. (1) The reactions of an individual cow to pups and to human presence vary greatly from day to day. (2) Supplementary and contingent feeding occurs in undisturbed as well as disturbed colonies. (3) Suckling usually follows soliciting by the pup. Acceptance by the cow may or not be preceded by olfactory investigation of the snout of the pup. (4) Between prolonged periods of sleep, strong pups will usually solicit cows and usually locate the teats readily. Weaker animals, which seldom sleep, have been seen sucking at seaweed, bulls, the boots of an observer and each other. (5) The precipitate departure of a suckling cow when disturbed may interrupt a pup's feeding only briefly because the pup may succeed in immediately resuming feeding from another cow. (6) A cow whose pup has been killed and removed may seem to search for it for a few days, but will accept and feed other pups meanwhile. (7) A cow suckling her own pup may be vigorously dispossessed by a strange cow which takes over the feeding temporarily.

The following provisional conclusions can be drawn. (1) A pup seen feeding from a cow is usually, but not necessarily, the offspring of that cow. (2) A pup abandoned by its cow will not necessarily starve to death. (3) A cow deprived of her pup will still feed other pups; she thus remains in the breeding colony and does not necessarily have a reduced chance of mating. (4) There is considerable power of recovery from disturbance which is not too frequent or prolonged.

These points are of considerable interest in relation to the way in which grey seal colonies, especially in the north-east Atlantic area, have elaborated into highly social groups. A puzzling feature of this development is that it increases pup mortality, a point which has been used by those who advocate the reduction of seal numbers on the grounds of alleviating the conditions of overcrowding. But a comparison with some herbivore populations does not apply to the grey seal; the animals choose this mode of life even when culled or when there is an abundance of space available into which they could spread.

Probably the grey seal was originally an ice-breeding species[3], but where it breeds on ice today it does so in ones and twos[4]. Only in temperate and therefore secondary habitats have the seals developed slum dwelling. More than three-quarters of the world's stock of the species now breeds in such conditions and in several places it has been reported to be increasing remarkably[5]. Thus despite an Arctic origin and a mortality that rises with density there is apparently some selective advantage in closely crowded colonies.

Coulson and Hickling, reviewing possible explanations for this[2], point out that pup mortality results in reduced recruitment to the breeding stock. Wynne-Edwards has suggested that social breeding is a means of preventing the undesirable effects of overpopulation by stabilizing numbers below a critical level[6]. Coulson and Hickling suggest that the self-induced pup mortality caused by grey seals choosing to breed in crowded conditions may be a means of preventing the numbers increasing beyond the limits of the food supply. But it is difficult to accept that the relatively few grey seals in the north-east Atlantic, whose feeding habits are catholic and opportunist, could be limited by the food available to the adults at sea. But this is a reasonable suggestion with regard to the food available before weaning.

The grey seal now has a remarkably shortened period of lactation and a dramatic rate of post-natal growth; it must obtain sufficient blubber for temperature control, streamlining and mechanical protection, and food reserve, as efficiently as possible. This situation is extreme among mammals and it is possible that pup mortality, which increases the opportunities for supplementary and contingent feeding, is a means of restricting recruitment to those fit enough to benefit in competition for milk. In other words, density dependent pup mortality could be a means whereby the milk supply in the colony or rookery as a whole is diverted to the genetically or physiologically fitter individuals. As Wynne-Edwards has observed[6], it is eugenically preferable to rear one or two healthy young than six or seven weak ones.

Uptake of Organic Solutes by *Nereis virens*

WHILE investigating aspects of the trophic relationships of benthic animals, we have studied the uptake of amino-acids and other small organic molecules by the polychaete worm, *N. virens*, which lives in great numbers on the north side of the lower Thames Estuary[1]. Work on the isolation of possible organic solutes has already been reported[2], and while no specific substances have yet been identified from surface water collected on Thames Estuary flats at Southend-on-Sea, other workers have reported the presence of quantities of organic material in sea water from various sources (for example, Duursma[3]).

Stephens[4-6] has shown the uptake of nutrients by invertebrates. References to earlier work, which started with that of Pütter[7] and was continued by, among others, Krogh[8], will be found in Stephens's papers.

The work summarized here is a laboratory study of some aspects of the absorption of glutamic acid by specimens of *N. virens* weighing between 2 and 5 g. There are contradictory accounts of the food and feeding of *N. virens* in the literature, for example, Verrill[9] and Gross[10]. Our observations indicate that except during the summer months, the gut appears to be empty of obvious foodstuffs. A more thorough study of this is, however, being made.

After acclimatization in the marine aquaria of the laboratory, animals were weighed and placed individually in sterilized sea water containing glutamic acid labelled with carbon-14. At the end of the uptake period (usually 1 h) the specimens were each placed in 80 per cent ethanol (25 ml./g of worm wet weight) for 48 h, after which samples of the extracts were counted in a liquid scintillation counter together with samples of the original nutrient sea water. Uptake of glutamic acid was then calculated and expressed as μg/g wet weight/h. Similar results were obtained in experiments in which the animals were ligatured at both ends showing that absorption is independent of the gut.

Absorption from different concentrations of glutamic acid is shown graphically in Fig. 1, which shows that uptake is not directly proportional to concentration and thus is unlikely to be the result of simple diffusion. In these experiments it was also shown that glutamic acid was concentrated against a gradient, and further, that when the reciprocal of amino-acid uptake rate was plotted against the reciprocal of the external concentration, the resulting graph resembled that of a typical enzyme–substrate reaction (Lineweaver–Burk plot).

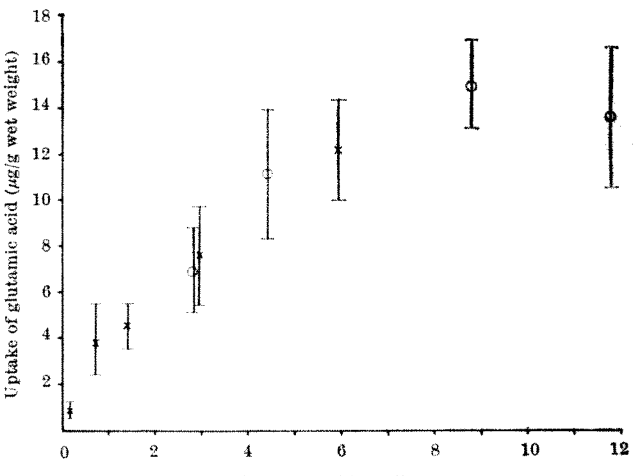

Fig. 1. Graph showing the effect of concentration on the direct uptake of glutamic acid by *Nereis virens*. ×, Experiment 12; ○, experiment 13. Lines represent standard deviations.

The active nature of the uptake process is also shown by experiments using amino-acids of similar configuration which acted as competitive inhibitors. Other unrelated amino-acids were shown to be absorbed independently.

Estimations of the amounts of glutamic acid which can be absorbed from a solution of 2×10^{-5} moles/l. could account for about 15 per cent of the animal's measured oxygen uptake if metabolized as an aerobic respiratory substrate. We have shown the animal to be able to take up a range of organic compounds including not only a variety of amino-acids, but also succinic, glycollic and citric acids and glucose. It is likely therefore that the overall process is significant in the worm's economy.

Gynodioecy in *Origanum vulgare*: Computer Simulation of a Model

THE population dynamics of the rare male sterility factors, or of gynodioecious species, which have a characteristically high proportion of female (male-sterile) and hermaphrodite individuals together in a population, is interesting to both evolutionists and plant breeders. Many workers have discussed the evolutionary significance of such a mating system, which promotes outbreeding with the proportion of females regulating the degree of outbreeding (for example, refs. 1–3). In *Origanum vulgare* (Labiateae), Lewis and Crowe[4] estimated that nearly 30 per cent, or even as many as 50 per cent, of females occur in various European populations. They showed that two loci govern the gynodioecy system; a dominant factor F causes anther suppression in combination with the recessive class hh to give $FFhh$ and $Ffhh$ as females, whereas HH, Hh suppress factor F to yield the other seven genotypes as hermaphrodites. Furthermore, certain segregation ratios suggested to them that the females are maintained through almost lethality of $ffhh$, lower viability of HH genotypes and poorer seed output of hermaphrodites than females. Thus if the fitness values are denoted by the matrix

$$\begin{array}{cc} & \begin{array}{ccc} FF & Ff & ff \end{array} \\ \begin{array}{c} HH \\ Hh \\ hh \end{array} & \begin{pmatrix} y & y & y \\ w & 1 & w \\ x & x & z \end{pmatrix} \end{array}$$

their data suggest that z is nearly 0, $y = 0{\cdot}25$ to $0{\cdot}50$ and $x > w$.

This basic model of Lewis and Crowe[4] can be readily generalized for theoretical studies by simulation on digital computer. Assume that loci F and H are linked with recombination value c, hermaphrodites practise mixed selfing (s) and random outbreeding ($t = 1 - s$), and that Hh have higher self-fertility than HH, hh classes so that the relative seedset from among the selfed ovules are in the ratio $s/a : s/b$, respectively (a, b are input constants). The value of x may be taken as constant between generations (model A) or varied by a frequency-dependent relation, say, $x_{n+1} = (k - \varphi_n)/\varphi_n$ (model B), where k is taken between 1 and 2, and φ_n = frequency of females in the preceding generation. A large number of deterministic sets were run with varying input values of selection and mating system parameters (a, b, s, c, x, y, w, z) of which only a few selected cases are reported here to illustrate briefly the interrelationships among these parameters in terms of the conditions allowing the maintenance of gynodioecy and, in particular, to discuss the selective forces postulated[4]. The simulation procedure involved the use of recursion equations between genotypic frequencies in the nth and $n+1$th generations solved iteratively for finding equilibria, the stability of which is tested either by using various initial frequency sets or by small perturbations in equilibrium frequencies. In most cases, initial allelic frequencies were assumed to be $p_F = 0{\cdot}01$ and $p_H = 0{\cdot}2$ or $0{\cdot}5$ so that females are initially rare depending also on the value of p_H. Note that (w,x) are fecundity parameters and (y,z) are relative viabilities.

For both models A and B, the values of y and z were found to be critical in that $y > 0{\cdot}50$ and $z > 0{\cdot}25$ often gave equilibria with only hermaphrodites ($\varphi = 0$), $p_H = 1$, and locus F polymorphic unless heterozygote advantage was very strong ($0{\cdot}90 < x < 1{\cdot}0$, $w = 1$). For $y = 0{\cdot}25$ or $0{\cdot}50$ and $0 < z < 0{\cdot}10$ (compare ref. 4), on the other hand, the equilibrium proportion of females (φ_e) was usually in the range 0·25–0·40. Some examples of these equilibria are given in Table 1. Note that for y and z in low range, the other parameters have relatively little influence on the equilibrium values of φ, p_F and p_H. Both loci are maintained polymorphic in this case, although polymorphism at H is a sufficient condition for maintaining gynodioecy. Both inbreeding and linkage tend to give higher values of φ and $\overline{W}$, the mean population fitness, as measured by the usual frequency weighted selective values. The effect of self-fertility parameters, a and b, can be seen from Table 2; the set of values ($a = 5$, $b = 1$) simply yields an effectively higher selective advantage favouring Hh over HH, and vice versa in the case of set ($a = 1$, $b = 5$). As expected, the values of (t,c,y) become critical in certain combinations for the retention of gynodioecy in a population. Note that the critical value of t becomes greater as the value of y

* Value in 500th generation; steadily approaching unity.

increases. In some cases linkage value can also be critical in terms of maintaining the females in population (for example, $y=0\cdot25$, $t=0\cdot10$, $b=5$). A similar pattern is noted for other sets of values of (w,x,t,c) with varying critical bounds in these situations.

Likewise, the interactions among the various parameters are rather complex for model B involving frequency dependent x (Table 3) with further effects of initial frequencies on the equilibria. Usually, for $p_H=0\cdot2$ where initially females are more frequent, wider conditions allow the maintenance of gynodioecy at equilibria than is the case with $p_H=0\cdot5$. The role of linkage and t depends, as already noted, on the value of y. Most nontrivial equilibria here too maintain females (φ_e) in the range 0·25–0·40 with $p_F=1$ and locus H polymorphic; in contrast, equilibria with $\varphi=0$ have $p_H=1$ and a low value of p_F at equilibrium. With model B and $a=1$, $b=1$ (that is, no self-sterility), in all cases stable equilibria were reached and t had little effect on the equilibrium values of φ and p_H as long as y and z are in rather low range. Thus most sets seemed to involve one or two peaks near *FFH*- or *FfHH*, especially when y and z play a critical part in comparison with the other parameters having little effect.

Thus the results from computer simulation support Lewis and Crowe's[4] model of selection which they arrived at through disturbed segregation ratios in certain progenies of wild individuals and not from any direct estimates of the selective forces in a natural population. The theory further points to the relative importance of various selection parameters which are critical for maintaining the gynodioecious system in *Origanum vulgare* and similar situations. Further data are needed, of course, to test certain ramifications of these models by direct estimates of selection and mating system parameters, for example, the amount of selfing, self-sterility and heterozygote advantage based on the experimental studies over generations. Male-sterile factors, in general, require rather strong selection for maintenance in natural conditions so that opportunities exist of measuring the selective differences in natural populations and are likely to be of great importance in the evolution of genetic systems, especially in predominantly selfing species[5] or homomorphic, self-fertile species[3]. Baker[3] recently discussed the evolution of breeding systems in *Armeria* and *Limonium* which suggest the origin of gynodioecy as a secondary system promoting outbreeding. An increase in the relative efficiency of the selfing component on hermaphrodites in a self-compatible form might impose counterpressure for greater outbreeding by maintaining a larger proportion of females and vice versa. Examples are now known of such a balance of various forces involved in the evolution of mating systems (for example, *Vicia faba*[6]). Ross (ref. 7 and personal communication) has recently described an interesting situation in *Plantago lanceolata* with a rather complex genetic system involving a combination of self-incompatibility and gynodioecy. Thus *Armeria*, *Origanum* and *Plantago* perhaps illustrate various combinations of the self-sterility and gynodioecy systems such as to represent three different stages in the evolution of self-compatibility from self-incompatibility. An understanding of the population dynamics of these mixed systems in terms of various selective forces and controlled breeding experiments would seem worthwhile.

Moss growing on Living Papuan Moss-forest Weevils

LARGE leaf-feeding weevils[1] of the genus *Gymnopholus* (subgenus *Symbiopholus*)[2], and certain other weevils, particularly of the genus *Pantorhytes*[3,4] (broad-nosed weevils), as well as certain cryptorhynchine weevils[3] and other beetles[3,5], all inhabiting fairly high moss forest ridges and summits, mostly in eastern New Guinea, have been reported to carry small gardens on their backs. The association seems to involve symbiosis, with the weevils providing a favourable environment for the plants, and the plants endowing the weevils with a protective resemblance to cryptogram-covered parts of plants, or with chemical protection.

Living in the plants are phytophagous oribatid mites[6] of a family known only from this association, and also sessile rotifers and minute nematodes, as well as other microscopic organisms.

The plants previously reported from the backs of the weevils (and sometimes on their femora) are fungi, algae, lichens and liverworts, as well as stray diatoms. Now the presence of moss can be reported. *Daltonia angustifolia* Dozy and Molk. (Figs. 1 and 2) of the Hookeriaceae has been determined from ten weevils of five species. These are *Gymnopholus* (*Symbiopholus*) *acarifer* Gressitt[2], Bulldog Rd., 2,400 m, G. A. Samuelson, 1966; *G.* (*S.*) *lichenifer* Gressitt[2], Bulldog Rd., 2,300 m, O. R. Wilkes, 1966; *G.* (*S.*) *fungifer* Gressitt[2], Saruwaged Range, 2,400 m, Samuelson, 1966; *G.* (*S.*) *reticulatus* Marshall[7], Daulo Pass, 2,500 m, Bismarck Range, L. Gressitt, 1955; and *G.* (*S.*) *carolynae* Gressitt and Sedlacek[8], Kubor Range, 2,950 m, Carolyn Gressitt, 1966.

The weevils on which the moss was found vary from about 22 to 36 mm long. Hepatics occur fairly abundantly on some of the weevils bearing moss, and in most cases fungi and algae are also present. Among the liverworts on these specimens are *Cololejeunea*, *Lejeunea* and *Metzgeria*. While one of us (J. L. G.) was in New Guinea in 1967, Dr R. Schuster visited the principal study area and identified *Odontolejeunea*, *Microlejeunea* and *Metzgeria* from cryptorhynchine weevils on Mount Kaindi. Dr Schuster also recognized a fern gametophyte on *Gymnopholus* (*S.*) *lichenifer*, but it was unfortunately lost. The moss-bearing weevils carried hardly any lichens.

The following plants have been recognized from the various weevils (partly identified by R. K. Benjamin, M. Hale, J. Proskauer and R. Schuster). Fungi–Fungi Imperfecti: ?Leptostromataceae, ?Nectrioidaceae; Ascomycetes: Helotiaceae, ?Micropeltaceae; Algae–Trentepohliaceae, Chroococcaceae, Nostocaceae, Oscillatoriaceae (or Scytonemataceae) and other algae; Lichens—Physciaceae (*Physcia* sp., *Anaptychia* sp.), Parmeliaceae (*Parmelia P.* (*Hypotrachyna*) *crenata* Kurok., *P. reticulata* Tayl., etc.); Hepaticae—Metzgeriaceae (*Metzgeria* sp.), Lejeuneaceae (*Cololejeunea* sp., *Lejeunea* sp., *Microlejeunea* sp., *Odontolejeunea* sp.); Musci—Hookeriaceae (*Daltonia angustifolia* Dozy and Molk.).

The weevils bearing the plants are mostly modified structurally in ways which provide niches and protection for the plants, particularly in their early stages. Among these modifications are pits, depressed areas surrounded by ridges and stiff setae, pubescent areas protected by tubercles, and others. It seems that evolution is progressing rapidly among these weevils. Populations on mountains separated by rather slight distances tend to be different, and several species-groups may be represented on one mountain. Already more than fifty species of *Gymnopholus* are known[2,8] and a similar number of *Pantorhytes*[4]. In spite of indications of rapid evolution, however, the plants and animals in this association must have been living together in a very humid environment for a considerable period of time. The weevils feed on a number of genera of dicotyledons[8,9].

Preliminary observations seem to verify the assumption that most of the plants growing on the weevils are those usually found on the surface of leaves and bark in the same environments. In the case of the lichens there is evidence of vegetative reproduction on the weevils. In the case of the moss, there are numerous protonemata on the weevils, which suggests that the origin may be from spores. It was earlier suggested that the fungivorous mites, of which up to seventy-five individuals have been found on one weevil, may transport propagules from one host to another.

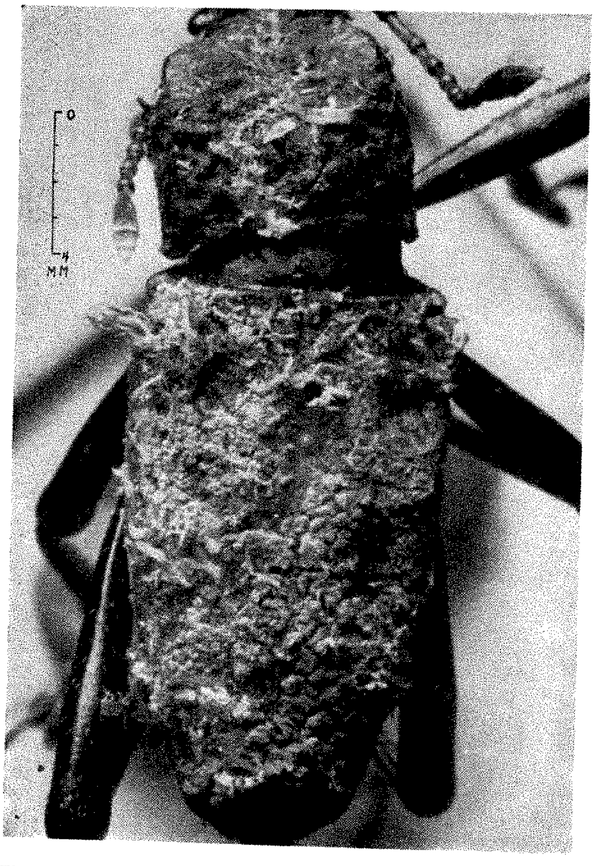

Fig. 1. *Gymnopholus* (*Symbiopholus*) *fungifer* Gressitt, Saruwaged Range, Huon Peninsula, north-east New Guinea, Samuelson, 1966, bearing the moss *Daltonia angustifolia* Dozy and Molk., as well as partial thick mat of fungi and algae and numerous hepatics.

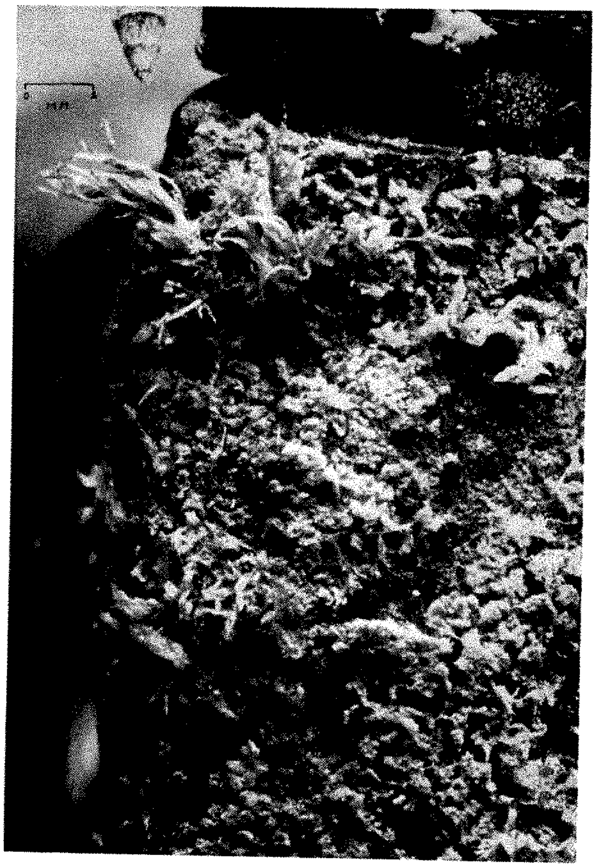

Fig. 2. *Gymnopholus* (*Symbiopholus*) *fungifer* Gressitt, Saruwaged Range, Samuelson, 1966, showing *Daltonia angustifolia* on base of left elytron, and the hepatics *Cololejeunea* sp. and *Metzgeria* sp. near centre of figure and *Lejeunea* sp. near bottom of figure.

Field observations so far suggest that predation of the weevils is relatively uncommon. The weevils may be distasteful to predators, or their large, heavily sclerotized bodies may be a deterrent, and (or) the plants growing on them may offer camouflage or be distasteful to predators. For more than a year individuals of *G.* (*S.*) *lichenifer* have been marked and released on the summit of Mount Kaindi, 2,350 m. Many of the weevils were collected on the upper slopes of the mountain, in forest, but released on host-bushes planted around the periphery of the flattened and cleared summit, around the communications repeater station. Although the weevils are thus in a very exposed situation, maintaining their habit of climbing to the top shoots of the plants at night and in foggy weather, almost no evidence of predation has been observed. Recovery rates of marked individuals have been as high as 43 per cent for individuals released within a few weeks preceding[8]. At least one weevil has been seen more than a year after marking. Several weevils have been observed to walk away into the forest after release, and some have been observed to die apparently of old age, so the reduction is obviously not primarily from predation. Only one killed individual was found, and this was on a log at night, so the enemy may have been a mammal. The weevil was not chewed up; only the abdomen had been removed.

New Glycolipid specific to Nitrogen-fixing Blue-green Algae

The polar lipid fractions from blue-green algae are usually simpler than those from higher algae and leaves, and normally contain only those four acyl lipids that are commonly associated with chloroplasts, namely, mono- and di-galactosyl diglyceride, sulphoquinovosyl diglyceride and phosphatidyl glycerol[1,2]. Occasionally, other components are reported[1,3].

Thin layer chromatography on silica gel of chloroform–methanol extracts from three nitrogen-fixing blue-green algae (*Anabaena cylindrica*, *Anabaena flos-aquae* and *Chlorogloea fritschii*) has, however, indicated the presence in all three of a substance which has not yet been detected in any other class of photosynthetic tissue.

In the chromatographic conditions used, this substance migrated a little faster than standard phosphatidyl ethanolamine (Fig. 1). When the chromatograms were reacted with sulphuric acid[4], the unknown substance gave a purplish-red colour commonly observed with glycosides, and a positive reaction with a Schiff–periodate reagent[4] was also obtained. It gave negative reactions with reagents specific for phosphate groups[5].

To obtain further analytical data for this material, the lipids of *A. cylindrica* were fractionated by column chromatography on DEAE cellulose[6]. The unknown lipid was slowly eluted from the adsorbent with 5 per cent methanol in chloroform, the later fractions displaced by this solvent containing increasing quantities of a compound which during thin layer chromatography seemed to be slightly more polar than the principal fraction, but which gave similar colour reactions with specific reagents. No clear cut separation of the two glycoside fractions could be achieved by column chromatography and for the preliminary studies described here they were examined as a mixture.

The crude glycoside was freed from contaminating pigments by crystallization from 90 per cent aqueous methanol to give a colourless amorphous solid, melting point 95°–102° C.

The principal absorption peaks obtained by infrared spectroscopic analysis of the glycoside were caused by methylene and hydroxyl groups. No significant absorption at wavelengths associated with ester or amide groups was observed, indicating the absence of acyl residues.

The glycoside was stable to aqueous and alcoholic alkali, but was hydrolysed when refluxed with 2 N sulphuric acid in methanol–water (95 : 5 v/v) for 28 h. After dilution with water, the reaction mixture was extracted with chloroform. The aqueous phase from this extraction gave a positive Molisch test and paper chromatography of a portion of this phase yielded two chief fractions which gave positive reactions with aniline phthalate[7] and ammoniacal silver nitrate[8] reagents, and which had R_F values similar to those for galactose and glucose.

Analysis of the chloroform layer by thin layer chromatography on silica gel using chloroform–methanol (90 : 10 v/v) as mobile phase gave two spots: a principal one of R_F 0·6 and a minor one of R_F 0·5. Thus the heterogeneity of the crude glycoside of *A. cylindrica* may be the result of, in part at least, the presence of two aglucone components of differing polarities. Infrared analysis of the crude aglucone showed strong adsorption at frequencies corresponding to methylene and hydroxyl groups. The aglucone fraction of the glycoside of *A. cylindrica* probably consists therefore of a heterogeneous mixture of fatty alcohols, members of which may contain differing numbers of hydroxyl groups.

Chromatographic studies on the corresponding lipid fractions from the two other nitrogen-fixing blue-green algae suggest that these are also heterogeneous, and it would seem that these organisms possibly contain families of alcoholic glycosides in which differences in composition of both the aglucone and glycoside moieties occur.

Such glycosides seem to be specific to nitrogen-fixing blue-green algae and we have been unable to detect comparable compounds in blue-green algae which do not fix nitrogen (including *Anacystis nidulans*, *Anabaena variabilis*, *Spirulina platensis*), yellow algae (*Vaucheria sessilis*, *Monodus subterraneus*), brown algae (*Fucus serratus*, *Fucus vesiculosus*), a red alga (*Porphyridium*

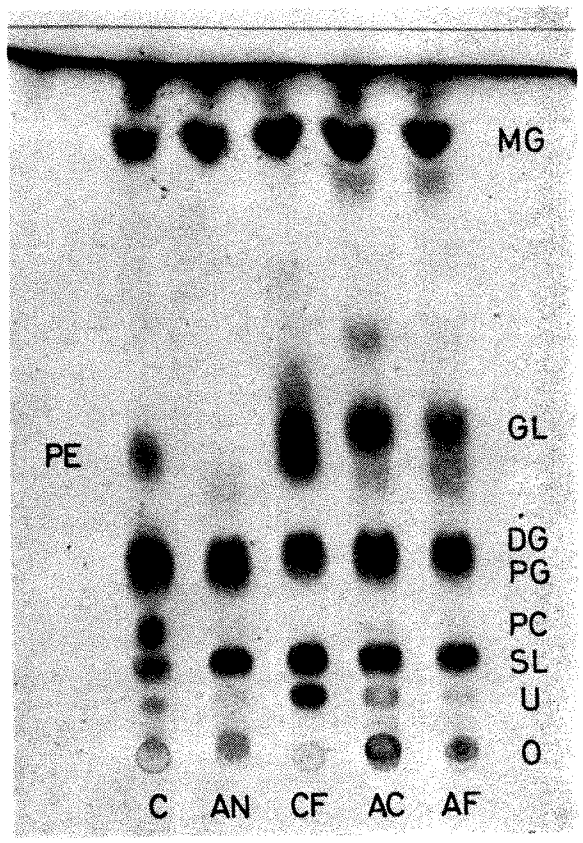

Fig. 1. Thin layer chromatography of lipid extracts from *Chlorella vulgaris* (C), *Anacystis nidulans* (AN), *Chlorogloea fritschii* (CF), *Anabaena cylindrica* (AC) and *Anabaena flos-aquae* (AF). Stationary phase: silica gel containing 10 per cent gypsum. Mobile phase: chloroform–methanol–acetic acid–water (85 : 15 : 10 : 3·7 v/v). Visualization: 25 per cent sulphuric acid at 220° C (5 min). Identification of components: monogalactosyl diglyceride (MG); the unknown glycolipid (GL); phosphatidyl ethanolamine (PE); digalactosyl diglyceride and phosphatidyl glycerol (not separated) (DG, PG); phosphatidyl choline (PC); sulpholipid (SL); an unidentified lipid (U); origin (O).

cruentum), green algae (including *Chlorella vulgaris*, *Chlamydomonas pulsatilla*), a marine diatom (*Phaeodactylum tricornutum*), a freshwater diatom (*Nitzschia palea*) *Euglena gracilis* and *Ochromonas danica*. They were also absent from lipid extracts from the leaves of several species of higher plants.

Present work is directed towards the preparation of homogeneous glycoside and aglucone fractions in order to determine their detailed chemical structure.

Availability of Nitrogen to Plants in Acid Coal Mine Spoils

MINING of coal by either strip (open cast) or deep-mining methods leaves large quantities of raw rock overburden and waste on the surface and revegetation of such spoils presents great reclamation problems. Survival and growth of plants are hampered by a variety of physical and chemical features of the spoils; in particular, poor growth has been attributed to lack of plant nutrients, especially nitrogen. Nevertheless, investigations of anthracite coal mine spoils in the vicinity of Tamaqua, Pennsylvania, showed that the nitrogen available to plants may be very abundant in certain spoils composed of black pyritiferous shales.

Cornwell[1] classified the spoils of the Tamaqua area into five lithological groups: black pyritic shales; grey calcareous shales; buff sandstones; "oxidized-surface" spoils coloured yellow by oxidized iron compounds; and "surficials"—mixed deposits of subsoil and unconsolidated substratum. Small areas of "placeland" (remnants of native soil) were scattered among the spoil heaps.

The apparent total nitrogen content of the < 2 mm fraction of these materials was determined by a standard Kjeldahl procedure employing overnight predigestion. The results reported in Table 1 show high nitrogen contents in the black shales. Two successive digestions of the black shales revealed that 88 per cent of the total nitrogen was removed in the first digestion.

Table 1. APPARENT TOTAL NITROGEN OF LITHOLOGICAL SPOIL TYPES OF THE TAMAQUA AREA

		Total nitrogen (%)	
	n	Mean	Range
Black acid shales	24	0·54	0·30–0·69
Grey shales	3	0·17	0·12–0·21
Buff sandstones	8	0·14	0·10–0·23
Oxidized-surface	5	0·16	0·14–0·16
Surficials	4	0·10	0·07–0·10
Placeland*	3	0·26	0·18–0·34

Analyses were based on the unground < 2 mm fractions and single Kjeldahl digestions.

* A horizon.

Differences in availability of nitrogen among spoils were suggested by the appearance of gray birch, *Betula populifolia* Marsh., which was the most common tree on all spoils and essentially the only plant on the most acid ones. Birch saplings on the buff sandstone spoils had thin narrow crowns and small pale green leaves; those on the black acid shales had dense crowns and large, dark green leaves. Such differences were borne out by analyses of foliage samples from all the spoils and placeland, as shown in Table 2. The nitrogen status of birch on the strongly acid black shales (*p*H in water 2·8–3·9) at least equals that on placeland, and is markedly higher than that from the other rock spoils. These results can only be attributed to the release of fossil nitrogen from the shales.

Table 2. NITROGEN CONTENT OF MATURE *Betula populifolia* FOLIAGE ON VARIOUS SPOIL TYPES

Buff sandstones	Grey shales	Oxidized-surface	Surficials	Place-land	Black acid shales
1·51	1·68	1·88	2·34	2·41	2·47

n = 20: older and younger leaves from ten sites on each spoil type, each sample from ten trees. Values not connected by a horizontal line differ at the 5 per cent level.

It has been known for several decades that rocks, particularly sedimentaries, contain appreciable amounts of nitrogen as "fixed ammonium", kerogen and possibly other organic forms[2–5]. Recently, both Stevenson[6] and Southard[7] have shown that fixed ammonium constitutes a large proportion of the nitrogen in various carbonaceous shales. The release of nitrogen from the Tamaqua spoils is suggested by conventional analyses of the < 2 mm fraction for readily soluble nutrients[8]; soluble NO_3–N and NH_4–N did not exceed 10 p.p.2m. except on the strongly acid black shales where NH_4–N ranged from 11 to 25 p.p.2m.

Further evidence of release was provided by analysis of soluble salts accumulated on spoil materials during two greenhouse trials. Both used spoils from two locations on both the black and grey shales; the bulk samples were passed through 0·25 or 1 in. sieves, and 350 g or 650 g of the sieved spoil was placed in small containers to which distilled water was supplied from below through nylon wicks. After approximately 11 months, the salt-encrusted upper spoil was extracted with water and the soluble constituents were determined. Selected results, expressed on the basis of the entire 350 or 650 g, are shown in Table 3. Both spoil types contained pyrite (FeS_2) which oxidized to yield the large quantities of sulphate shown.

Table 3. CONTENT OF WATER SOLUBLE ELEMENTS IN PYRITIC SPOILS AFTER 11 MONTHS WEATHERING WITHOUT LEACHING, UNDER GREENHOUSE CONDITIONS

		Al	NO_3	NH_4	SO_4
			(mequiv./kg)		
Grey shales					
Sample 1	< 1″	0·8	0·17	0·39	94
	< 0·25″	0·4	0·22	0·21	69
Sample 2	< 1″	1·6	0·06	0·47	171
	< 0·25″	1·1	0·06	0·21	171
Black shales					
Sample 1	< 1″	104	0·32	8·5	226
	< 0·25″	22	0·05	3·7	62
Sample 2	< 1″	59	0·16	4·5	165
	< 0·25″	21	0·06	3·8	66

In the grey shale extracts, the sulphate anion was largely neutralized by calcium and magnesium, possibly derived from authigenic and cementing carbonates. In strong contrast, reactions from 2·7 to 3·2 in the black shale extracts and the abundance of soluble aluminium indicated an intensely acid weathering environment in which some destruction of silicate lattices must have occurred. Such destruction would necessarily liberate "fixed ammonium" as well as organic compounds containing nitrogen. If the latter are resistant to microbial attack, as has been supposed, the nitrogen values of Table 3 may largely represent fixed ammonium. In any case, the ammonium liberated from the black shales over the period of 11 months is of the order of 1–2 per cent of the total nitrogen (assuming 0·6 per cent) and certainly the quantities are large enough (100–240 p.p.2m.) materially to affect vegetation and to account for the high foliar contents shown in Table 2.

Certain inferences follow (*a*) The active weathering fraction in pyritic spoils includes fragments of any size which contain oxidizable sulphur, rather than being confined to the silt and clay-sized fractions, as in most soils Rapid weathering of the acid black shales in the field was indicated by coatings of secondary iron compounds, pronounced rounding of fragments and reprecipitated gypsum (*b*) Percolates from such spoils must contribute substantial amounts of nitrogen, as well as other elements, to outflowing ground-water and streams (*c*) Spoils containing little oxidizable sulphur, or having a high ratio of calcium and magnesium to sulphur, do not undergo much silicate destruction, and may therefore release little nitrogen, regardless of total content or form. Although Schramm[9] found that nitrogen deficiency limited plant growth on black shale wastes, the *p*H of his study materials ranged from 4 6 to 5 2, indicating minimal sulphide oxidation and silicate destruction

PSYCHOPHARMACOLOGY

Effects of Drugs on Conditioned "Anxiety"

THE behavioural phenomenon known as conditioned suppression was first demonstrated by Estes and Skinner[1] They maintained the bar-pressing activity of rats by a schedule of food reinforcement and found that this behaviour decreased in frequency during a stimulus which ended with an unavoidable shock Estes and Skinner suggested that the suppression of responding was an indirect measurement of "anxiety" Subsequent workers[2] have argued that the temporal relationships between the shock and the stimulus which precedes it satisfy the requirements for classical (respondent) conditioning to occur After a number of pairings, the conditioned stimulus (pre-shock stimulus) elicits the respondents which were formerly elicited only by the unconditioned stimulus (shock)

This interpretation has led to research programmes in which conditioned suppression has been used as a model of clinical anxiety. For example, the responding of rats is less suppressed during a pre-shock stimulus if they have recently received electro-convulsive shocks[3] It might therefore be suggested that conditioned "anxiety" is alleviated by this treatment.

In 1956, Brady investigated the effects of amphetamine and reserpine on conditioned suppression[4]. The results are summarized by his illustration (Fig 1). These cumulative records show (top) the effects of the Estes–Skinner procedure in control conditions (saline) When amphetamine was administered, the baseline rate of responding increased, but the number of responses emitted during the pre-shock stimulus decreased in comparison with control animals Reserpine produced opposite effects the baseline behaviour decreased in frequency but more responses were made during the pre-shock stimulus than had been made in the control conditions Brady claimed that "the method described does provide an approach to the selective assessment of specific drug-behaviour relationships in the affective sphere while providing a control for the general behavioural and motor disturbances that frequently develop as non-specific side effects of such

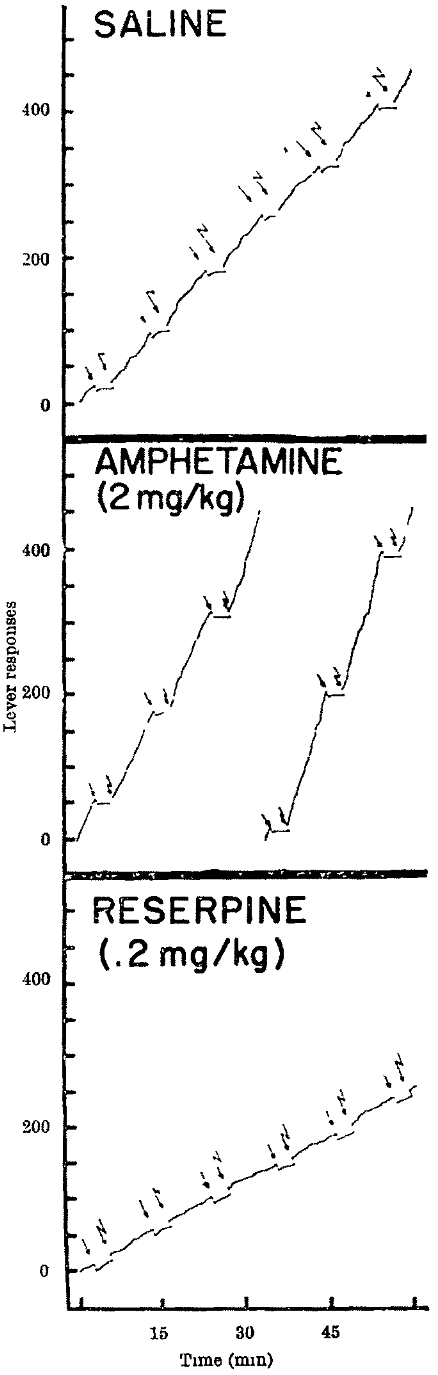

Fig 1 The effects of amphetamine and reserpine on conditioned suppression The pen of the cumulative recorder was deflected during the pre-shock stimulus (Reproduced from the article by J V Brady, *Science*, 123, 1033, 1956)

drug administration". Thus reserpine reduced "anxiety", because more responses were emitted during the pre-shock stimulus although the baseline responding became less frequent

A recent report[5] casts doubt on this claim In this experiment, attention was directed only to observable behavioural events; conditioned suppression was studied without regard to affective states such as "anxiety" The experiment was designed to discover whether frequency of responding can act as a determinant of conditioned suppression when all other variables known to be relevant are controlled (for example, frequency of reinforcement, shock intensity, deprivation, etc) This was done by means of paced variable interval schedules[6] Two rats were used so there was a control for possible sequence effects Both rats were first exposed to a condition (*A*) in which bar-presses were reinforced by food at variable intervals which averaged 1 min Then reinforcements became available just as before, but rat 1 obtained these only if it responded at a high rate, and rat 2 only if it responded at a low rate (*B*) Finally (*C*), these conditions were interchanged. Conditioned suppression was obtained with a standard procedure in each phase of the experiment

The results are summarized in Fig 2 They are strikingly similar to those reported by Brady, although no drug was used The behavioural baselines were affected by the pacing procedures in a way similar to that caused by Brady's two drugs Responding during the pre-shock stimulus also changed as it had done in Brady's experiment When the overall response rate was high, there was less responding during the pre-shock stimulus than there was in the control conditions. Similarly, when the overall response rate was low, responding occurred more frequently during the pre-shock stimulus than it had in control conditions These results suggest that Brady's findings do not necessarily show a specific pharmacological effect on "anxiety" His changes in effect were measured by conditioned suppression The changes in suppression may have been the direct result of changes in the behavioural baseline, rather than an effect exhibited despite contrary changes in this baseline. Brady's results alone are not firm evidence that amphetamine enhances "anxiety", nor that reserpine attenuates it.

PHYSIOLOGY

Human Power Output

It has been known for a long time that power output in man increases rapidly with decreasing duration of exercise, but there have been few systematic studies of this problem Indeed, measurements of the power output of the body during a single movement lasting one-tenth of a second or less have not been made

We have investigated the peak power output in forty-seven men and eight young women, whose physical details are given in Table 1, during the performance of a standing vertical jump off both feet from a force platform Each

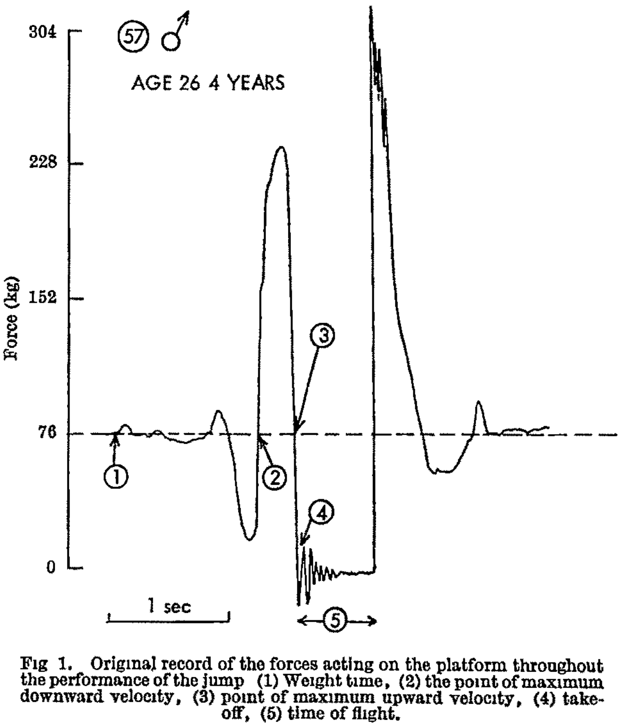

Fig 1. Original record of the forces acting on the platform throughout the performance of the jump (1) Weight time, (2) the point of maximum downward velocity, (3) point of maximum upward velocity, (4) take-off, (5) time of flight.

subject was allowed three practice jumps and the best of three experimental jumps was recorded and later analysed in the following way

Table 1 PHYSICAL CHARACTERISTICS OF THE FIFTY-FIVE SUBJECTS INVESTIGATED

Subjects	Age (yr)		Weight (kg)		Height (cm)	
	Mean	*S D*	Mean	*S D*	Mean	*S D*
Males ($n = 47$)	32 7	8 9	74 9	10 0	172 9	6 6
Females ($n = 8$)	22 1	3 9	60 0	7 5	163 6	6 0

The trace (Fig 1) was measured to an arbitrary scale at intervals of 0 02 s using an Oscar trace assessor (Benson–Lehner, Ltd) and the readings were compared with measurements of zero and known body weight to obtain a measure of force Acceleration (A) of the centre of gravity was found from $A = \dfrac{9\ 81 \times (F - W)}{W}$ M/s^{-2}, where F is force and W is body weight, and velocity was obtained by integration of the area under the A curve Values for instantaneous power were determined from the product of force and velocity Typical examples of such analysis are shown in Fig 2

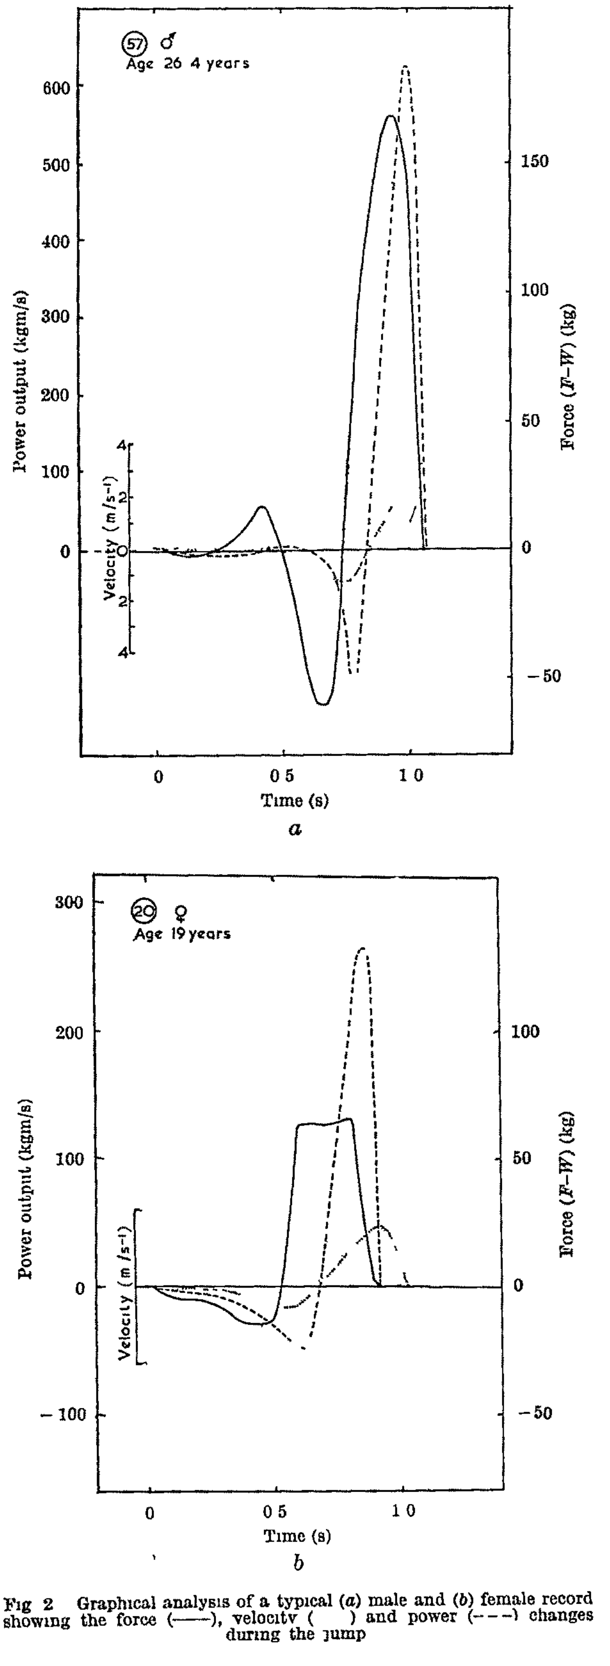

Fig 2 Graphical analysis of a typical (*a*) male and (*b*) female record showing the force (——), velocity ( ) and power (- - -) changes during the jump

Table 2 COMPARISON OF MAXIMUM POWER OUTPUT DURING SUSTAINED WORK ON A BICYCLE* ERGOMETER AND A STANDING VERTICAL JUMP FROM FORCE PLATFORM

Subjects	Power output (h p)			
	Bicycle ergometer		Force platform	
	Mean	*S D*	Mean	*S D*
Males ($n = 47$)	0 33	0 04	5 23	1 19
Females ($n = 8$)	0 25	0 03	3 15	0 48

* The power output was determined from direct measurements of oxygen consumption during the sixth to eighth minute of maximal work as a separate experiment

The results obtained on the fifty-five subjects expressed in terms of horsepower (h p) are shown in Table 2 The mean peak power output for the men was 5 22 ± 1 56 h p. and for the women 3 15 ± 0 48 h p These figures are among the highest ever recorded—they are some fifteen times greater than the corresponding values for maximum aerobic power achieved during sustained exercise on a bicycle ergometer (Table 2), and extremely close to the theoretical maximum postulated for man

Promotion of 4-Hydroxy-3-methoxyphenylglycol Formation in Man by Reserpine

The ability of reserpine to bring about the depletion of biologically active amines in mammalian tissues[1] is well known This alkaloid also has several other biochemical effects which have recently been reviewed[2], and we report a new and potentially important action of reserpine on catecholamine metabolism which was revealed during the course of another experiment[3]

Six normal male volunteers, aged from 24 to 46, were given 1 25 mg of reserpine intravenously Urine was collected after 1, 3, 6, 9, 12 and 24 h. One month earlier, each subject had received an intravenous injection of placebo, and urine was collected at similar time intervals Samples were acidified with 6 N hydrochloric acid to *p*H 2, and stored in the cold until assayed for 4-hydroxy-3-methoxymandelic acid (VMA) (ref 4) and 4-hydroxy-3-methoxyphenylglycol (HMPG) (ref 5)

In agreement with the observations of other authors[6,7], there was a significant increase in the output of VMA during the test compared with control periods (Fig 1) This reached a peak in the 3–6 h collection and fell to normal by 12–24 h Predictably, but apparently for the first time, we also noted that reserpine gave rise to a significantly increased excretion of HMPG (Fig 2) which similarly reached a peak after 3–6 h The output of this compound was still significantly raised in the 12–24 h sample

Both compounds derive from the intermediate aldehyde formed from the oxidative deamination of noradrenaline and adrenaline (for review see ref 8) Perhaps the most interesting finding in this work is that there was a proportionately greater increase in the output of HMPG in response to reserpine injection (Fig 3), pointing to some diversion of the intermediate aldehyde from an oxidative to a reductive pathway of metabolism It may be relevant that Rutledge and Weiner[9] have produced *in vitro* data to suggest that noradrenaline, synthesized endogenously in the rabbit atrium from labelled dopamine, is predominantly inactivated to the glycol This tendency is exaggerated when the animal has previously been reserpinized (although the authors do not comment on this finding)

The mechanism of the reserpine-induced shift described here is not yet understood Others have observed a similar change after ethanol administration[10,11], both in the noradrenaline pathway and in the analogous 5-hydroxytryptamine route of metabolism[12] While a possible increase in the concentration of NADH$_2$ has been invoked to explain the shunting effect provoked by ethanol[11], it is more likely that some other mechanism is responsible for our finding, for Tyce *et al* [13] could not detect any alteration in ^{14}C-5-hydroxytryptamine metabolism in perfused reserpine-pretreated rat liver despite the predicted metabolic shift after ethanol perfusion

Disulfiram[10] and calcium carbimide[14] will induce similar *in vivo* changes, presumably by inhibition of aldehyde dehydrogenase, although it is just as likely that the reserpine effect is produced by activation of the complementary enzyme, aldehyde reductase, whether this latter enzyme is a distinct entity or whether one enzyme catalyses both reactions is still unknown[14].

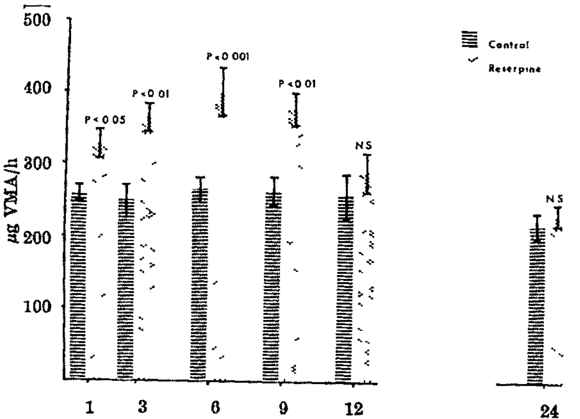

Fig 1 Means ± *S E* of timed urinary output of 4-hydroxy-3-methoxymandelic acid (VMA) (μg/h) in six subjects before and after a single intravenous injection of 1 25 mg of reserpine N S, Not significant

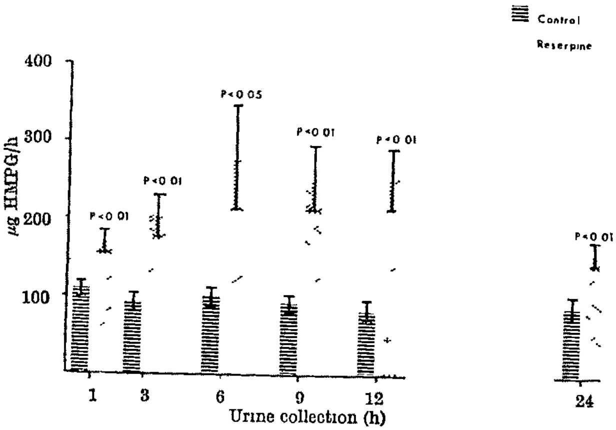

Fig 2 Means ± *S E* of timed urinary output of 4-hydroxy-3-methoxyphenylglycol (HMPG) (μg/h) in six subjects before and after a single intravenous injection of 1 25 mg of reserpine

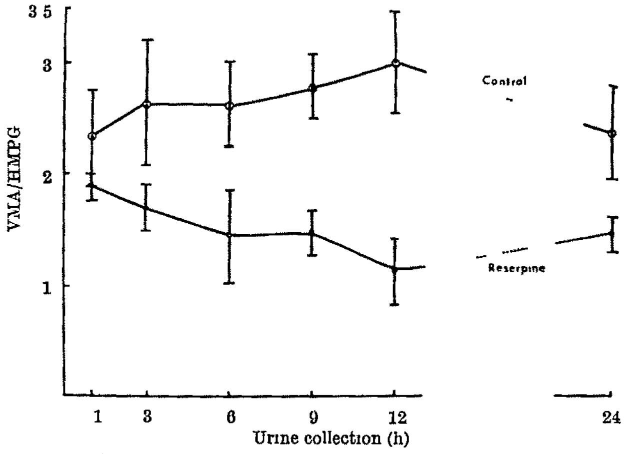

Fig 3 Ratios of means ± *S E* of urinary VMA to HMPG output in six subjects before and after a single intravenous injection of 1 25 mg of reserpine

There is one further possibility which deserves consideration It may be that the enzyme which brings about further oxidation of the aldehyde lies within the noradrenaline storage granule to which reserpine impairs access, thus facilitating aldehyde reduction.

We thank Sister M F Gonzales and Staff Nurse P J Williams for invaluable assistance, the volunteers; Mrs P Jomain for technical assistance, and Hoechst Pharmaceuticals, Ltd, who defrayed the salary of M B H Y

Effect of Cocaine, Desipramine and Angiotensin on Uptake of Noradrenaline in Tissues of Pithed Rats

SYMPATHETIC nerves have been shown to be the site of uptake of circulating noradrenaline The extent of sympathetic innervation of an organ seems to determine the uptake of radioactive noradrenaline after intravenous injection if allowance is made for the volume of blood

Table 1. EFFECT OF COCAINE, DESIPRAMINE AND ANGIOTENSIN ON NORADRENALINE UPTAKE AND ON BLOOD PRESSURE RESPONSES TO NORADRENALINE IN PITHED RATS

Treatment	Predrug BP (mm Hg)	Maximum ΔBP (mm Hg)	Total radioactivity (mμCi/g) Heart	Skeletal muscle	Kidney	Adrenal gland	Aorta
Saline	60 ± 2.6	81 ± 3.0	92 ± 4.8	3.5 ± 0.3	125 ± 12.4	30 ± 3.4	16 ± 2.4
Cocaine	68 ± 2.8*	118 ± 1.9*	38 ± 1.9*	3.5 ± 0.2	144 ± 13.0	18 ± 1.8*	11 ± 3.0*
Desipramine	74 ± 3.0*	114 ± 3.3*	37 ± 1.8*	4.0 ± 0.4	150 ± 21.7	16 ± 0.4*	8 ± 0.9*
Angiotensin	64 ± 1.5	92 ± 2.4*	94 ± 5.3	3.9 ± 0.6	130 ± 9.3	33 ± 2.2	14 ± 1.0

Each blood pressure (BP) value or heart total radioactivity value is the mean ± S.E.M. of ten or eleven animals.
Each skeletal muscle, kidney, adrenal gland and aorta total radioactivity value is the mean ± S.E.M. of five or six animals.

* Denotes a significant difference ($P < 0.05$) from corresponding saline control values.

flow to the organ and its endogenous noradrenaline content[1].

Cocaine and desipramine have been shown to be potent inhibitors of noradrenaline uptake by the isolated perfused rat heart[2], and the potentiation of noradrenaline responses by cocaine and desipramine has been demonstrated in the isolated vas deferens of the rat[3]. Angiotensin (at a high concentration) is known to cause some inhibition of noradrenaline uptake by spleen, thoracic aorta and brain stem slices *in vitro*[4].

We have studied noradrenaline uptake *in vivo* utilizing the pithed rat preparation to determine whether the effects of cocaine, desipramine and angiotensin were similar in a variety of tissues. Exactly 30 min after pithing—while the blood pressure was being recorded—rats were injected with cocaine (10 mg/kg) or desipramine (1 mg/kg) or infused with angiotensin (0.03 µg/kg/min) or saline (0.004 ml./min). Fifteen minutes after injection or the start of an infusion, 2 µg (10 µCi)/kg of ^{3}H-7-DL-noradrenaline was injected intravenously. After 2 min the animal was killed and the total radioactivity of the heart, thoracic aorta, skeletal muscle, kidney and adrenal glands was determined by the procedure described by Van Zwieten, Widhalm and Hertting[5].

The blood pressure and radioactivity results obtained in this study are shown in Table 1. The variation of radioactivity recoverable was probably a result of the pressure of different numbers of sympathetic nerve endings in these tissues. The uptake of noradrenaline by heart, adrenal gland and thoracic aorta was significantly inhibited by cocaine and desipramine but not by angiotensin. The uptake of noradrenaline by skeletal muscle and kidney apparently was not affected by any of the agents. Studies of noradrenaline uptake in intact and immunosympathectomized rats[6] indicate that uptake by skeletal muscle and kidney is significantly reduced in the presence of a subnormal population of sympathetic nerve endings, and therefore it was expected that noradrenaline uptake in these tissues would be reduced by treatment with cocaine or desipramine. These experiments did not show whether the accumulation of noradrenaline by skeletal muscle and kidney from the circulation was significantly influenced by the relative blood flow to each tissue, by the ability of the tissue to extract the delivered noradrenaline[7] or by the more persistent noradrenaline blood concentrations resulting from the apparently defective uptake by other tissues.

The blood pressure responses to noradrenaline after cocaine, desipramine and angiotensin had been given were significantly facilitated. There seems to be a correlation between facilitation of noradrenaline blood pressure responses and inhibition of noradrenaline uptake after administration of cocaine and desipramine. None of the tissues utilized seemed to give any indication of a defective uptake of noradrenaline in the presence of a physiological concentration of angiotensin sufficient to cause a facilitation of the noradrenaline blood pressure responses.

Fixation Tremor in relation to Eyeball–Muscle Mechanics

THE fixation tremor of the eyes can be recorded by using a small accelerometer which is fixed to a contact lens[1]. This technique has made it possible to determine the changes in the spectral composition of the tremor in various circumstances. In particular, we report here the results obtained when weights are fixed to the lens, so increasing the effective moment of inertia of the eyeball. These results yield information about the mechanics of the eyeball–muscle system.

The subject, wearing a close-fitting contact lens, lies supine and fixates on a black spot 3 mm in diameter at a distance of 2 m. The accelerometer is plugged into a 'Perspex' tube which is cemented to the lens. Small brass weights are stuck to this tube with 'Plasticine'. The output voltage from the accelerometer is amplified, passed through a band-pass filter (5–250 Hz), and then integrated electrically, thus obtaining an angular velocity-versus-time record of the tremor. The record is stored on the screen of a storage oscilloscope, and later photographed on 35 mm film. A specially designed digital potentiometer[2] is used to sample ordinates of the traces at intervals of 3 ms. The ordinate values are supplied to a digital computer, which is programmed to compute the autocorrelation function, and, from this, the velocity spectral density (VSD) function in the usual way[3].

Fig. 1 shows a typical series of VSD graphs. Each graph has been computed from 800 data points. When the eye carries only the contact lens and accelerometer (graph *a*) there is a main peak in the spectrum at 40 Hz. As the inertia is increased, this peak is seen to move downwards in frequency. There is also a reduction in the amplitudes of the high frequency components of the spectrum. These results can be interpreted in mechanical terms. The tremor waveform can be considered to be the "output" of a mechanical filter, the "input" to which is the force developed by the active component of the muscles in normal tone. The characteristics of the filter are fixed by the moment of inertia of the eyeball, the elastic stiffness of the muscles and the viscous damping of the system[4]. When considering VSD graphs, the filter is of the band-pass type. A peak of transmission is expected at the mechanical resonance frequency of the system. This frequency is lowered as the inertia of the system is increased. The main peak in the graphs of Fig. 1 is identified with the mechanical resonance frequency of the eyeball–muscle system.

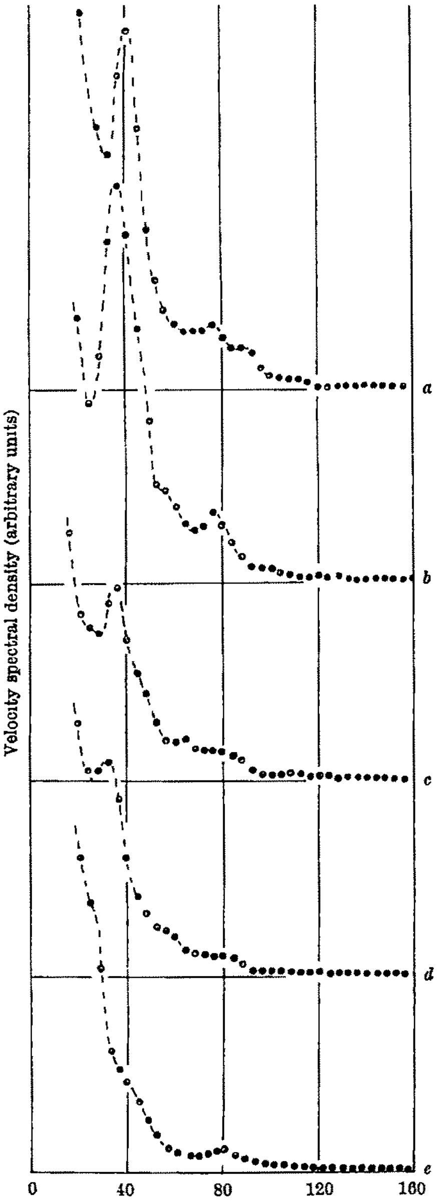

Fig 1 Velocity spectral density graphs which have been computed from records of elevation–depression tremor The graphs show the effect of loading the eye by fixing weights to the contact lens, thus increasing the moment of inertia of the eyeball The values of the added inertia for graphs *a*, *b*, *c*, *d*, *e* are 5, 6·1, 7·3, 10 and 12 g cm² respectively

From experiments in which the eye is vibrated by external forces, Thomas has formulated a model of the eyeball–muscle system[4]. The resonance frequencies deduced from the present work are 20–30 per cent lower than those which have been predicted from the model, but, in spite of this discrepancy, the present results must be considered to give strong support to the general validity of the model, in contrast to the model proposed by Robinson[5] (supported by Childress and Jones[6]) in which the system is stated to be " . heavily overdamped, has no resonant frequency and is little affected by the mass of the eyeball".

A small peak at 70–80 Hz can be seen in the graphs of Fig 1 When a correction is made for the loading effect of the lens and its attachments, or when tremor is recorded by a method which does not impose any loading of the eye[7], this peak is much more pronounced Its frequency is not changed by loading the eye, and so it is associated not with the mechanics of the system but with the "input" to the system—that is, with the fluctuations in muscle tension, and thus with the stream of tonic impulses to the muscles

The attenuation of the high frequency components of the tremor which is caused by inertial loading will have occurred in the experiments of previous workers who have used a mirror on a contact lens to record eye movements

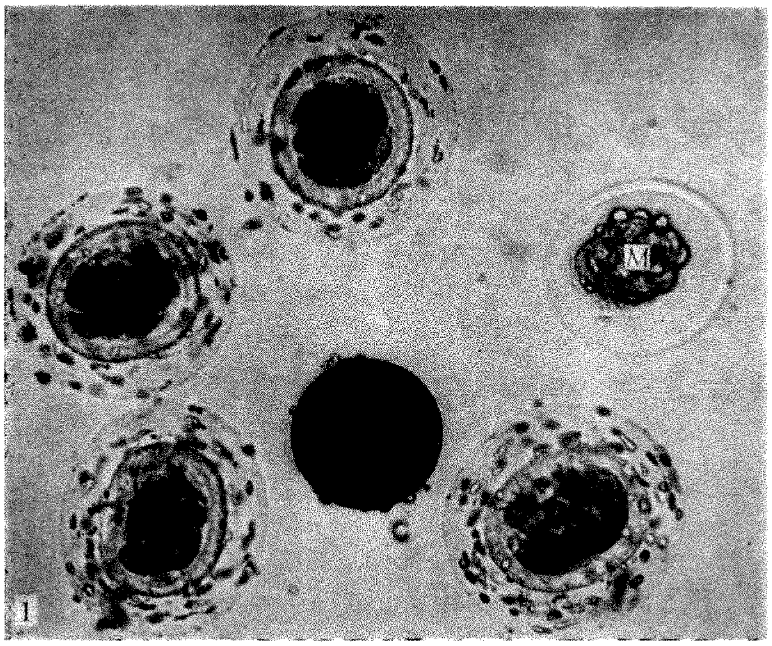
Effect of an Intra-uterine Device on Uterine Motility in the Rhesus Monkey

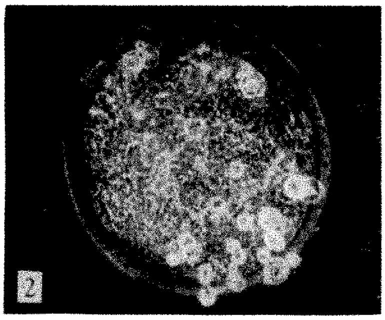
WE recently observed[1] that although an intra-uterine device (IUD) did not affect ovulation and fertilization, it was contraceptive in the rhesus monkey. The pattern of tubal transport was not markedly disturbed, but eggs could not be recovered from the uterus in IUD monkeys It was inferred that the principal contraceptive effect of the IUD is probably exerted within the uterus, to cause either premature expulsion and/or premature destruction of the fertilized egg The presence of an IUD may therefore disturb the pattern of uterine motility in the rhesus monkey

We have attempted to explore this possibility by recording the pattern of uterine motility in eight IUD and seven control rhesus monkeys at various times during consecutive menstrual cycles A chronically implanted, strain gauge transducer[2] was used and this was attached to the ventral serosal surface of the uterus, connected to a miniature plug in the vagina, and thence to a twin-channel recording system ('Oscillo-riter', Texas Instruments, Inc) An external transducer was attached to the monkey's chest to monitor both respiratory activity and gross bodily movements Recordings were made over a period of 1–3 h with the conscious monkey seated in a restraint chair The monkey was habituated to this restraint and tolerated it without undue stress

Some convincing records of uterine motility were obtained, but usually the record was distorted by respiratory or gross bodily movements Thus although the transducers were sensitive to variations in uterine motility and abdominal pressure, they did not provide a direct and quantitative means of comparing uterine motility

The possibility that eggs are prematurely expelled from the uterus in the presence of an IUD was then tested by determining the fate of artificial and natural substitutes for rhesus monkey eggs after they had been surgically transferred to the uterus Initially, groups of three silver (110*m*)-coated resin spheres (R A eggs) were used as artificial substitutes These R A eggs were similar in size and density to natural monkey eggs, and resembled those used by previous workers[3] In subsequent experiments, fertilized rabbit eggs were transferred as natural substitutes together with a single R A egg, which acted as a marker to facilitate transfer





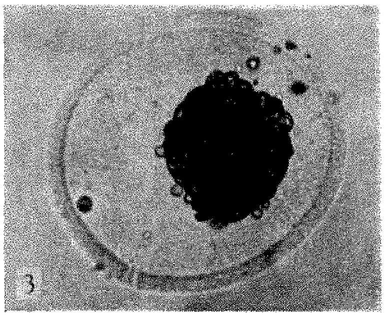


Fig. 1. Four rabbit eggs, one radioactive egg and a normal monkey morula (*M*) recovered from a control monkey on day 18.

Fig. 2. Degenerate, unfertilized monkey egg from the uterus of an IUD monkey on day 17.

Fig. 3. Degenerate monkey morula from the uterus of an IUD monkey on day 18.

R.A. and rabbit eggs were transferred to twelve control and twelve IUD monkeys on menstrual day 15, and to two IUD monkeys on day 18. The animals had regular menstrual cycles and had been caged with a fertile male for at least 3 days before transfer. At transfer, all except five monkeys had ovulated (Table 1): two of these animals had inactive ovaries and three had ovaries in a pre-ovulatory condition. The eggs were transferred in < 10 μl. of physiological saline by using a fine, nylon cannula attached to a micrometer syringe. At autopsy, the entire genital tract was removed and divided so that the uterus, cervix and vagina could be separately flushed with physiological saline. The uterus and cervix were then also monitored with a Geiger counter. With one exception, when eggs were flushed from the cervix, the transferred eggs were recovered only from the uterus.

The results of these experiments are summarized in Table 1. There was no difference in the recovery of transferred eggs between the control and IUD monkeys examined 48 h after transfer. Most of the R.A. and rabbit eggs could be recovered, and there was no evidence to suggest that premature expulsion from the uterus had occurred in the IUD monkeys.

At recovery, the appearance of the R.A. and rabbit eggs suggested that they were resistant to destruction within the monkey uterus (Fig. 1). The rabbit eggs had an intact and apparently normal zona pellucida, and the "albumen" layer, which had coated most of the eggs at the time of transfer, also seemed to be unchanged. The transferred eggs had virtually disappeared from the uteri of IUD monkeys examined at 72 h, and from the control monkeys at 96 h. Moreover, one control monkey examined 72 h after egg transfer yielded two rabbit eggs and an R.A. egg in the cervical flush, but nothing in the uterine flush. This evidence suggests that the transferred eggs were eventually expelled.

Table 1. RADIOACTIVE AND RABBIT EGGS RECOVERED FROM THE UTERUS AT AUTOPSY

Autopsy (h after transfer)	Group	Total monkeys (yielding transferred eggs/examined)	Total radio-active eggs (recovered/transferred)	Total rabbit eggs (recovered/transferred)

96	Control	1/2‡	0/2	1/14
Following transfer on day 18				
48	IUD	2/2*	2/2	13/18

* One monkey had not ovulated.

† Two monkeys had not ovulated.

‡ One monkey ovulated between laparotomy and autopsy.

It is interesting that at 72 h after transfer (Table 1) only one egg could be recovered from the IUD monkeys, and yet all the R.A. eggs and 36 per cent of the rabbit eggs were found in the controls. The results might suggest that the transferred eggs had a somewhat shorter uterine life in the presence of an IUD. It is not possible, however, to draw any precise conclusions on uterine survival from groups of animals which had to be examined at time intervals 24 h apart.

Additional results were obtained, at autopsy, incidentally to these experiments. Rhesus monkey eggs were recovered from two out of four control and two out of eight IUD monkeys, which were suitable for the recovery of naturally ovulated eggs and had ovulated by menstrual day 15. On day 18 a normal morula of forty cells (Fig. 1) was flushed from the uterus of one control monkey while an abnormal, eleven celled morula was recovered from the cervix of the other. In contrast to our previous observations[1], the two IUD monkey eggs were recovered from the uterus. One egg, recovered on day 17, was degenerate and unfertilized, but the other was a degenerate morula of more than twenty cells on day 18 (Figs. 2 and 3). The corpora lutea associated with the four eggs were similar in structure: according to Corner's histological criteria[4], they were approximately 6 days old. These naturally ovulated eggs had probably survived within the uterus for 2 or 3 days.

Our results do not provide convincing evidence that the contraceptive action of an IUD in the rhesus monkey results principally from the premature expulsion of eggs from the uterus. By inference, the evidence favours the alternative explanation that in the presence of an IUD fertilized rhesus monkey eggs undergo premature degeneration once they have entered the uterus.

Activation of Malathion by the Locust Bodywall

WE reported earlier[1] that dilution of malathion in the mineral oil KEB (kerosene extract bottoms) not only increases its toxicity to mature adults of the desert locust, *Schistocerca gregaria*, but also the speed of its action, when applied topically on the hind wing base. We later discovered[2] that the killing power of a 10 µg/g dose of malathion 2·5 per cent solution in KEB varies considerably with the site of application on the locust body. Thus it yielded a 100 per cent kill when applied topically to the neck membrane, no deaths at all on the hind femur and intermediate values for other sites of application. Injections into the body cavity were always less toxic than topical application in the same general area of the body. There was, however, no significant difference in the killing power of malaoxon (2·5 per cent solution in KEB) topically applied to the neck membrane when compared with its injection through the same membrane[3]. This led us to believe that topically applied malathion is converted to its $P=O$ analogue, malaoxon (which is more toxic and more rapid in action than malathion) by the locust bodywall and that the KEB only helps its penetration and conversion by spreading the insecticide on to a wider area of the insect bodywall. The experiments reported here were designed to show this activation by the bodywall as well as penetration differences and to explain the differences in toxicity and speed of action reported earlier[1].

Malathion labelled with sulphur-35 (both atoms labelled) was mixed with tritiated malathion (the carboethoxy part of the molecule labelled), in the ratio of approximately 1 : 5. Three solutions (w/v) were then prepared from this mixture using KEB as the diluent and mature males of *Schistocerca gregaria* were dosed at a rate of 40 µg/insect, applied on the hind wing base as a single drop of 0·2, 0·8 and 1·6 µl./insect of 20, 5 and 2·5 per cent solutions, respectively. An 'AGLA' syringe driven by a micrometer was used for dosing in each case and the insects were kept at 31° C after dosing. At intervals of 0, 2, 4, 6 and 8 h after dosing, each insect was washed thoroughly with acetone, dried and homogenized together with any excreta and extracted with chloroform and water[4]. A portion of each extract and acetone wash was counted in a Packard 'Tri-Carb' liquid scintillation spectrometer to determine the recoveries of sulphur-35 and tritium in each phase. Corrections were made for quenching of each nuclide and self-decay of sulphur-35 where necessary. Tritium activity thus provided a measure of the unabsorbed portion of the dose (acetone wash), its accumulation in the insect body as malathion and/or malaoxon[4] (chloroform extract) and the portion hydrolysed (water extract) at different time intervals. The loss of activity of sulphur-35 over that of tritium, on the other hand, provided a measure of the conversion of malathion to malaoxon (a 50 per cent loss being equal to a 100 per cent conversion).

Table 1. RECOVERIES OF SULPHUR-35 AND TRITIUM FROM DIFFERENT PHASES AFTER DOSING EACH INSECT WITH 40 µg OF DOUBLE LABELLED MALATHION IN THREE DIFFERENT SOLUTIONS OF KEB

Percentage of malathion in KEB (w/v)	Hours after dosing	Nuclide	Radioactivity recovered (%)				Loss (−) or gain (+) of ^{35}S over ^{3}H (%)

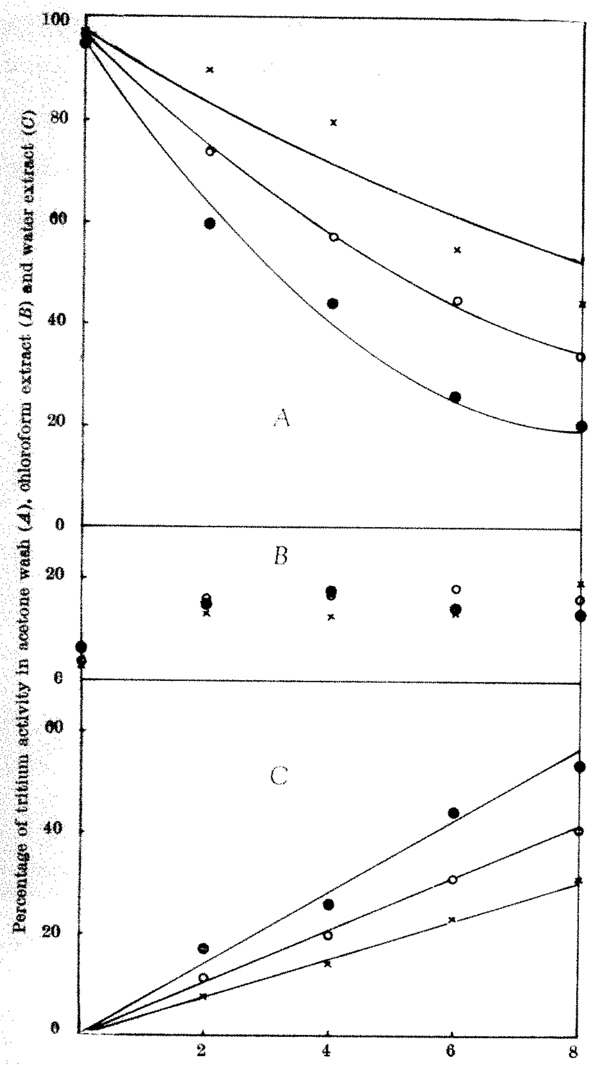
	2	^{35}S	62·8	16·0	13·6	92·4	+0·6
		^{3}H	59·9	14·9	17·0	91·8	
	4	^{35}S	46·0	19·1	20·7	85·8	−1·6
		^{3}H	43·9	17·5	26·0	87·4	
	6	^{35}S	27·5	14·4	37·6	79·5	−5·0
		^{3}H	26·6	13·7	44·2	84·5	
	8	^{35}S	21·7	14·1	43·7	79·5	−7·6
		^{3}H	20·7	12·9	53·5	87·1	

The results, an average of three replications in each case, are presented in Table 1. The results are complicated by two factors. One is that the sulphur-35 product of malathion metabolism is soluble in organic solvents and results in a change of the ratio of sulphur-35/tritium even in the acetone wash. This sulphur containing by-product is eventually lost, possibly in the form of a gas, resulting in an overall increase with time in the recoveries of tritium as compared with sulphur-35, thus showing clearly the formation of malaoxon. This increase was higher in the case of the 2·5 per cent solution than in the 5 or 20 per cent solutions, where there are differences, although not well synchronized, showing that more malaoxon was formed in the case of the dilute than the concentrated solutions of malathion in KEB. Quantitative estimations of malaoxon formation in the three solutions were not possible because of the recovery of excess sulphur-35 activity in the organic solvents. The second factor which made quantitative estimations difficult was the decrease in total recoveries of tritium activity with time. This is because of the difficulty of homogenizing the locust wings and legs which in time become radioactive[3], presumably as a result of the movement of hydrolysis by-products of malathion into these regions. The fact that water extracts always had a higher activity of tritium than sulphur-35 also indicates that hydrolysis takes place chiefly, if not entirely, from malaoxon rather than directly from malathion.

In Fig. 1, the tritium activities recovered in acetone wash, chloroform and water extracts are plotted against time. It will be seen that increased rates of penetration in cases of dilute solutions were counterbalanced by a corresponding increase in the rates of hydrolysis. If hydrolysis represents detoxification[5], and the chloroform extract has only malathion in it, then the differences exhibited here are so trivial that the significant differences reported earlier[1] in the toxicity of these three solutions can scarcely be explained satisfactorily. In fact, at the end of the experimental period the portion of the applied dose which could be extracted with chloroform was lowest in the case of more toxic 2·5 per cent solution and highest in the least toxic 20 per cent solution. These results can only be explained by assuming that in the case of dilute solutions more malathion is desulphurized into malaoxon, which is a more labile compound than malathion. This conversion results in corresponding increases in the rates of hydrolysis, and because the rates of penetration decrease with time more rapidly in the dilute solutions than the concentrated ones, whereas the rate of hydro-



Hours after application of 40 μg of labelled malathion/insect as 20 per cent (×), 5 per cent (○) and 2·5 per cent (●) solutions in KEB.

lysis in all cases is linear, at the end of the experimental period the chloroform extractable portion of the dose applied as dilute solution goes down.

Part played by Ciliate Protozoa in Rumen Function

IN general, the population of ciliate protozoa in the umen is large with more than 10^6 organisms/g of rumen ontents and a mass approximately equal to that of the umen bacteria[1]. These protozoa are known to possess ctive systems for hydrolysing carbohydrates, proteins nd lipids, but their effects on the efficiency of utilization of nutrients are not clear. In some experiments, removal of the fauna of the rumen has not influenced performance[2–4] while in others the patterns of rumen fermentation, growth rate and efficiency of food utilization were altered[5–7]. Protozoa have been implicated as causal agents in bloat, and Clarke[8] has shown that the introduction of an anti-protozoal agent to the rumen of cattle reduces the rate of rumen fermentation and the susceptibility to bloat.

Considerable day-to-day variation in the pattern of rumen fermentation (as measured by the molar proportions of steam volatile fatty acids present in the rumen liquor) has been observed in this laboratory, especially on diets low in fibre content. It has been postulated that this variation can be caused by a fluctuating population of ciliate protozoa in the rumen.

A short-term *in vitro* fermentation has been used in an attempt to study the effect on rumen fermentation of the ciliate protozoa of the rumen in mixed culture with rumen bacteria. In the three experiments reported, rumen liquor was donated by a rumen-cannulated sheep fed 800 g of concentrate and 92 g of hay daily. The ciliate protozoa were almost completely removed mechanically by centrifugation.

Centrifuged ("defaunated") and un-centrifuged rumen liquor were incubated for 1 h at 39° C either alone, or after adding a substrate consisting of 1 g of the concentrate fed to the donor sheep. Net production rates of total and individual steam volatile fatty acids were calculated by subtracting total production in the absence of substrate from that in the presence of substrate. The results are presented in Table 1.

The fall in the rate of production of *n*-butyric acid when ciliate protozoa were excluded from rumen liquor was striking, particularly in the first and third experiments. This fall was largely compensated by an increase in the rate of production of propionic acid. In all three experiments, the exclusion of ciliate protozoa raised the rate of production of *n*-valeric acid and depressed that of iso-valeric acid. Effects on the production of acetic acid were variable, there being a marked decline in rate of production in the first experiment but only slight reductions in the second and third experiments.

In the first two experiments, removal of the ciliate protozoa reduced the total rate of production of steam volatile fatty acids, a finding consistent with the removal of part of the biomass. In the final experiment, however, no such difference was observed. These variable effects on the rate of fermentation may be related to the initial size of the population of ciliates but, as yet, no attempt has been made to describe the population quantitatively.

Table 1. NET *in vitro* RATES OF PRODUCTION OF STEAM VOLATILE FATTY ACIDS IN RUMEN LIQUOR WITH OR WITHOUT THE PRESENCE OF CILIATE PROTOZOA

The final *p*H of the rumen liquor was consistently higher after fermentation in the absence of ciliate protozoa.

Similar but less dramatic effects on the fermentation process were observed when rumen liquor was fermented in the presence of an antiprotozoal agent (dimetridazole, May and Baker, England).

Changes in rumen fermentation of the magnitude observed in these experiments occurring *in vivo* could have important effects on the efficiency of utilization of energy for growth and milk production. Clearly further studies both *in vitro* and *in vivo* are necessary to determine more precisely the role of ciliate protozoa in the production of steam volatile fatty acids and to investigate factors, such as *p*H, which may determine the level of protozoal activity in the rumen.

Extracellular Recording from Single Neurones in the Olfactory Centre of the Cockroach

Very few reports have been published concerning the olfactory responses from single units in the central nervous system of invertebrates. This communication is concerned with the successful extracellular recording of single unit responses evoked by olfactory stimulation. It is emphasized that the response to odours can be classified into three categories: namely, "on" response; "on–off" response; and "off" response.

We used the adult American cockroaches *Periplaneta americana*, bred in the laboratory. An unanaesthetized cockroach was secured with pins and tape on a cork plate; its respiration was unhindered. A square section of the dorsal exoskeleton of the frons was removed to expose the olfactory centre. Electrolytically tapered tungsten needles with the insulation removed at the tip were used initially as recording microelectrodes, but these were later replaced by glass pipettes filled with 3 M potassium chloride with diameters of 0·5–2·0μ at the tip. The latter type of electrode was able to isolate single units more easily. The amplification and recording system was the same as that described earlier[1]. The microelectrode was inserted into the dorsal sensory neurone area of the deutocerebrum, and was advanced as far down as the outer margin of the ventral motor neurone area.

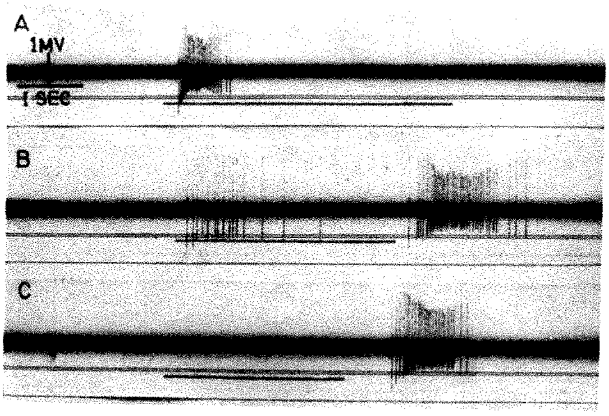

Fig. 1. Responses of a single olfactory neurone to odour stimuli. *A*, Propionic acid; *B*, acetic acid; *C*, acetic acid (10 s after the preceding stimulation shown in *B*). In each record, the horizontal black bar below the record indicates the period of stimulation.

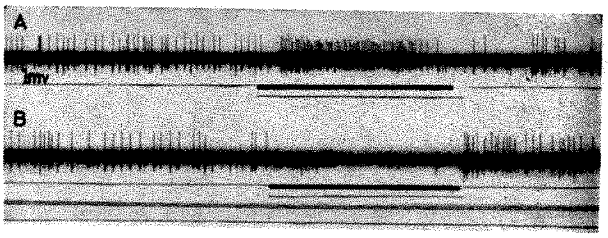

Fig. 2. Responses of olfactory neurones to propionic acid (*A*) and methyl-ethyl ketone (*B*). Time: 60 Hz.

Odorous air was applied to the surface of the antenna by squeezing a polyethylene bottle containing an odorous substance. During the course of penetration of the electrode, odour stimuli were repeatedly applied at regular intervals in order to ensure that the electrode did not miss neurones which were not spontaneously active. The odorous substances applied were propionic acid, acetic acid, acetone, methyl alcohol, hydrochloric acid and methyl-ethyl ketone. The experiments were performed at room temperature, about 20° C.

Unitary discharges were always observed when the microelectrode was advanced into the antennal lobe (the olfactory centre). Most units fired spontaneously, but some showed little or no spontaneous discharge. Fig. 1 shows the responses to odour stimuli of an olfactory neurone which shows no spontaneous discharge. Three kinds of response patterns were evoked by two types of odour stimuli. In Fig. 1*A*, the neurone stimulated by propionic acid produced an initial burst of discharges which soon ceased despite continuous stimulation ("on" response). Fig. 1*B* shows a typical "on–off" response caused by acetic acid. Fig. 1*C* shows an "off" response to an acetic acid stimulation which was applied 10 s after the initial stimulation (Fig. 1*B*). These "off" responses gradually became more pronounced as the time interval of acetic acid stimuli was shortened. The neurone that responded to propionic acid and acetic acid also responded to hydrochloric acid, but it failed to respond to other types of odour stimuli which included methyl-ethyl ketone, acetone and methyl alcohol, regardless of the concentration.

These results suggest that the neurones in the olfactory centre have a certain specific sensitivity to odour stimuli. An example of another type of sensitivity is shown in Fig. 2: the recording was made from a deeper region than that in Fig. 1, and spontaneous discharges were observed. The spontaneous activity permitted observation of the inhibitory as well as the excitatory effects of odour stimulation. Judging from the irregular spike heights, the responses may have been derived from more than one neurone.

Two types of odour, propionic acid and methyl-ethyl ketone, had different effects: propionic acid excited the neurones to produce a burst of discharges during the period of stimulation (Fig. 2*A*). The background impulses were temporarily inhibited immediately after the beginning of the stimulation. This is a kind of the "on" response shown in Fig. 1*A*. On the other hand, methyl-ethyl ketone inhibited the spontaneous discharges (Fig. 2*B*). The neurones that were inhibited by odour stimulation usually showed an increased activity immediately after the cessation of the stimulation. This resembles the "off" response shown in Fig. 1*C*.

In primary olfactory receptors of insect antennae, excitation ("on" response) and inhibition ("off" response) are known to be components of the odour response pattern of a receptor. The "on–off" response pattern has not, however, been recorded from the periphery[1–4].

It is interesting to note that the three patterns of responses observed in the olfactory centre of the cockroach are quite similar to those in the optic lobe of insects[5] and of the ganglion cells of the mammalian retina[6].

Conductance or Resistance?

IN circulatory physiology, there may be difficulty in expressing quantitatively the response of a vascular bed in which blood flow has altered If change of flow is used to express the response, then a large change in arterial pressure may be overlooked For this reason it has been customary to express responses as changes of resistance, vascular resistance being the pressure difference across the vascular bed divided by the flow through it

One disadvantage of this method can be appreciated when two simple examples are considered First, if flow changes from 50 ml /min to 2 ml /min, while the pressure difference remains constant at 100 mm of mercury, then the resistance changes from 2 to 50 units Second, if flow changes from 50 ml /min to 1 ml /min, while the pressure again remains constant at 100 mm of mercury, then resistance has changed from 2 to 100 units. In these examples the flow changes—48 ml /min and 49 ml /min—are similar and many flow meters would fail to register the difference between the two responses, but the resistance changes are 48 and 98 units, the difference between the two being large

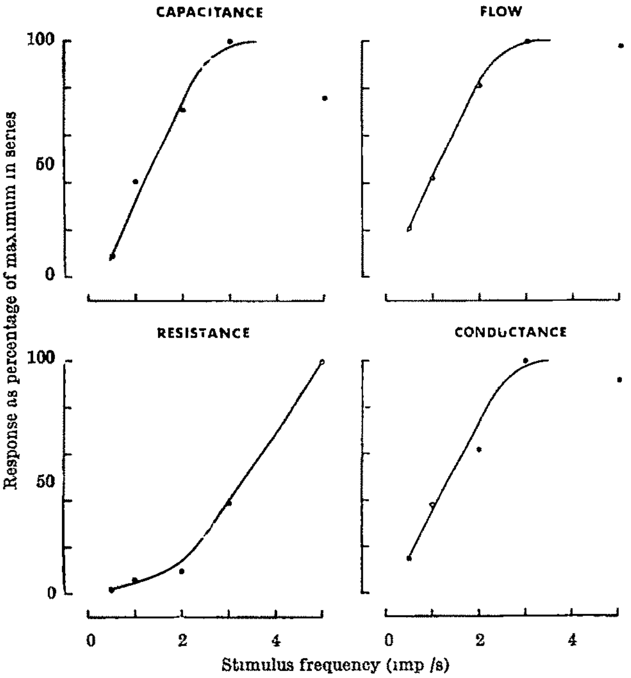

Fig 1 Capacitance, flow, resistance and conductance responses during splenic nerve stimulation These responses are measured as the differences between the pre-stimulation values of splenic weight, splenic artery flow, resistance and conductance and the respective values at the end of the second minute of nerve stimulation The differences are expressed as percentages of the maximum changes in each parameter (ordinates) and are plotted against the frequency of nerve stimulation (abscissae) Splenic weight change is a measure of capacitance change For details of the methods see ref 1

Vascular resistance is a derived term and is inversely related to blood flow. When vascular smooth muscle contracts, flow decreases and capacitance decreases but resistance increases Is it not then misleading to compare capacitance with resistance in conditions of nerve stimulation or drug infusion ?

Conductance, which is obtained by dividing flow by pressure difference, incorporates pressure but has a direct relationship to smooth muscle length In electrical terms it is more significant to compare conductance (A/V) with capacitance (A × s/V), rather than resistance (V/A) with capacitance In circulatory research, it is usual to disregard the pressure denominator when evaluating capacitance

Fig 1 shows the responses obtained in one cat when the splenic nerves were stimulated at frequencies between 0 5 and 5 impulses/s The changes in splenic weight (capacitance), splenic artery flow, resistance (pressure/flow) and conductance (flow/pressure) are expressed as percentages of the maximum responses in the series and plotted against the frequency of stimulation Smooth curves have been drawn Capacitance, flow and conductance each have a similar relation to frequency, but the resistance curve shows a marked separation from that of capacitance.

In conclusion, I feel that conductance is the most satisfactory method of expressing responses of a vascular bed in which blood flow or perfusing pressure changes

Heparin and the Stabilization of Fibrin

IN experiments to compare the activity of factor XIII (fibrin stabilizing factor) in serum and plasma, it was necessary to activate the factor XIII in plasma by addition of calcium, but to prevent the plasma from clotting Heparin was therefore used as an anti-coagulant Addition of heparin to the test system resulted in the factor XIII deficient substrate clot being rendered insoluble in 5 M urea or 1 per cent monochloracetic acid (MCA) without addition of a source of factor XIII An investigation of the effects of heparin on the solubility of fibrin in these reagents was therefore undertaken

During the final stages of blood coagulation, fibrinogen is converted, by the enzymatic action of thrombin, to fibrin monomer which will then spontaneously polymerize to form a fibrin clot This fibrin is soluble in reagents which will split hydrogen bonds such as 5 M urea or 1 per cent MCA and is referred to as soluble or unstable fibrin[1].

A further enzyme, factor XIII, which is normally present in plasma reacts with this unstable fibrin in the presence of calcium ions and converts it into a form which is insoluble in 5 M urea or 1 per cent MCA but which is soluble in 0·1 M 2-mercaptoethanol The enzyme is believed to be a transamidase[2,3] which is activated from a precursor form by thrombin[4] The molecular weight of factor XIII has been estimated as 350,000 A tendency to dissociate into inactive sub-units of molecular weight 110,000 has been observed[5] and this dissociation was inhibited by cysteine

Purified human fibrinogen (Kabi Grade *L*) was clotted with thrombin (Maws bovine 5 U/ml) in the presence of 0 5 mM calcium chloride and 5 mM cysteine After incubation for 60 min at 37° C, the clots, when mixed with an equal volume of 2 per cent MCA and left at room temperature, showed no sign of dissolution within 12 h When similar clots were formed without calcium or without cysteine they were soluble in 1 per cent MCA within 30 min If before the addition of MCA the clots were mixed with a 1/6 volume of heparin (Boots or Evans 160–170 U/mg, 1 mg/ml) and incubated for a further 60 min, they no longer dissolved when an equal volume of 2 per cent MCA was added A similar alteration of solubility in MCA could be produced by incubation with other heparinoids such as chlorazol fast pink or dextran sulphate (Pharmacia, molecular weight 50×10^3)

The insolubility of the heparin treated clots in MCA could be reversed by incubation with protamine sulphate, polybrene or toluidine blue Unlike the clots stabilized through the action of factor XIII, the clots treated with heparin were not soluble in 0 1 M 2-mercaptoethanol

When a human fibrinogen preparation, purified by DEAE chromatography (my unpublished work), or a fibrin monomer preparation purified by repeated clotting and dissolution of a fibrin clot[4] was clotted in the presence of calcium and cysteine, the clots were soluble in 5 M urea or 1 per cent MCA When treated with heparin, these clots were also rendered insoluble in MCA Plasma obtained from a case of congenital factor XIII deficiency, however, remained soluble in MCA despite treatment with heparin

Clots made from citrated plasma by addition of thrombin were found to be insoluble in 1 per cent MCA, whether formed without added calcium or with addition of calcium and cysteine If 0 2 mg/ml (final concentration) of polybrene, 0 4 mg/ml of protamine sulphate or 20 mg/ml of toluidine blue was added to the plasma before clotting the clots which formed without added calcium were then soluble in MCA while those with calcium added remained insoluble When clots were formed from plasma anticoagulated with 5 mg/ml of ethylenediamine tetraacetic acid–disodium salt (EDTA) they rapidly dissolved in MCA, but if these clots were incubated in heparin they, too, became insoluble in MCA These observations are summarized in Tables 1 and 2

The effect of other thrombin inhibitors was studied, but neither hirudin, soya bean trypsin inhibitor (SBTI) nor tosyl-l-arginine methyl ester (TAMe) could affect the solubility of the clot

The significance of these observations is difficult to assess The fact that heparin in the absence of ionic calcium renders fibrin clots insoluble both in MCA and in 2-mercaptoethanol suggests that the mechanism involved is distinct from that by which clots are stabilized through the action of factor XIII Similar considerations prevail if the stabilization of the purified fibrinogen and of the fibrin monomer was the result of trace contamination with factor XIII The possibility that the effect of heparin on MCA solubility was caused by the quantity of calcium which this reagent contained and which would allow activation of traces of factor XIII within the clot was excluded by estimation of the calcium present This revealed only trace amounts and neutralization of this calcium with EDTA did not prevent the alteration of MCA solubility by heparin

To 0 1 ml of the fibrin source were added 0 1 ml amounts of 2 5 mM calcium chloride, of 25 mM *l*-cysteine, of 5 mg/ml of EDTA or of 2 mg/ml protamine sulphate The volume was made up to 0 4 ml with 0 05 M glyoxaline saline buffer and 0 1 ml of bovine thrombin (Maw's topical thrombin, 5 U/ml) was added The clots were incubated at 37° C for 30 min, freed from the tube side by flicking and 0 1 ml of heparin 1 mg/ml or 0 1 ml of buffer was added The tubes were replaced at 37° C for 30 min and 0 6 ml of 2 per cent MCA then added The solubility of the clots was observed after a further 30 min at room temperature +, −, Presence or absence of reagent

S, soluble } 30 min after addition of MCA
I, insoluble }

Heparin is known to affect the zeta potential of fibrinogen[6] and to precipitate fibrinogen and other plasma proteins in certain conditions. If heparin were to stabilize clots by precipitating a "skin" of fibrin around the clot this precipitation might later be reversed by heparin antagonists EDTA has been observed to have a potentiating effect on the precipitation of fibrinogen by heparin by causing a reduction of *p*H, while serum inhibits the precipitation, possibly because heparin co-factor in the serum competes with fibrinogen for the available heparin[7] It is, however, not possible on these grounds to explain the failure of heparin to alter the solubility in MCA of clots prepared from the plasma congenitally deficient in factor XIII, nor the inhibition of stabilization of normal citrate plasma clots by protamine sulphate

The interpretation of these observations within the confines of the current theories of fibrin stabilization is difficult and their significance with regard to the physicochemical changes of fibrin stabilization remains to be explained

APPLIED SCIENCE

Ammonia–Oxygen Fuel Cell

EARLIER publications have shown that the 'Teflon'-bonded platinum black electrodes developed by Niedrach and Alford[1] for use in fuel cells with aqueous electrolytes are mechanically stable over a temperature range from 25° to 200° C and perform well with both oxygen and air and with a variety of fuels and electrolytes[1-6] This communication presents the initial results that we have obtained using these electrodes in a fuel cell operating with gaseous ammonia and oxygen and using 54 weight per cent aqueous potassium hydroxide as electrolyte Similar results have been obtained with aqueous caesium hydroxide as electrolyte[7]. The cell and auxiliary electrical equipment were essentially the same as those used for the methanol–oxygen fuel cell[2]

The performance curves (Fig 1) show the variation with current density of the resistance-free voltages between the ammonia anode and the oxygen cathode and between each electrode and a hydrogen reference electrode in the same electrolyte The platinum catalyst loading of each electrode was 51 mg/cm^2, and the total cell resistance was about 0 03 ohm As expected from previous experience with hydrogen–oxygen cells[1], the cathode curve showed no limiting current density up to at least

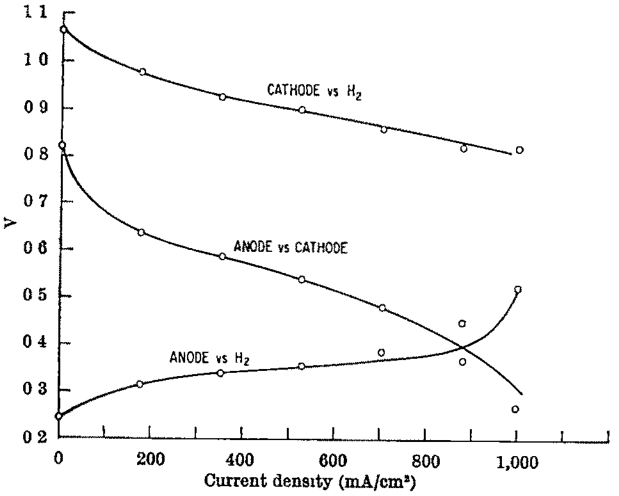

Fig 1 Performance of ammonia–oxygen fuel cell (No 73B) with 54 per cent KOH at 140° C IR-losses not included

1,000 mA/cm^2 The overall cell performance was limited by the anode, the voltage of which rose sharply at current densities above 700 mA/cm^2 Another anode, with a thicker layer of porous 'Teflon' on the gas side and with a lower limiting current density as a result, was operated over the range of temperatures and electrolyte concentrations shown in Fig 2 For current densities between 20 and 200 mA/cm^2 the anode performance improved by almost 75 mV as the temperature was increased from 109° to 191° C

The performance levels achieved in these ammonia–oxygen cells exceed those achieved with any fuels other than hydrogen or hydrazine Results have been reported[8] on an ammonia–oxygen fuel cell operating at 143° C with a mixed alkali hydroxide electrolyte containing only 12 per cent water and with porous nickel electrodes impregnated with platinum catalyst for the anode and silver catalyst for the cathode The Lockheed[8] cell voltage dropped to 0 5 V at a current density of only 35 mA/cm^2, even though its open circuit potential was about 130 mV higher than that shown in Fig 1 All other data published for ammonia–oxygen fuel cells[9,10] were obtained with either aqueous or fused alkali hydroxides immobilized in a porous matrix and with electrodes made of porous nickel or carbon and impregnated with platinum as the anode catalyst The maximum current densities reported for operation below 150° C were about 40 mA/cm^2 at a cell voltage of about 0 4 V, current densities of 120–130 mA/cm^2 were achieved only above 200° C

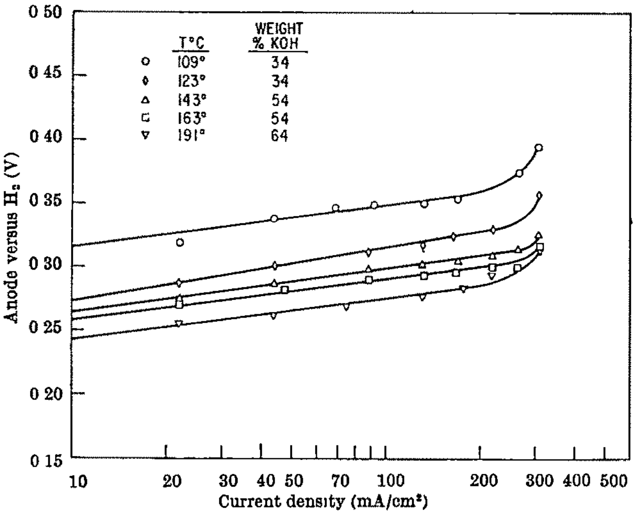

Fig 2 Effect of temperature upon anode performance (Cell 74) —○—, 109° C, 34 weight per cent potassium hydroxide, —◊—, 123° C, 34 weight per cent potassium hydroxide, —△—, 143° C, 54 weight per cent potassium hydroxide, —□—, 163° C 54 weight per cent potassium hydroxide, —▽— 191° C, 64 weight per cent potassium hydroxide

GENERAL

Holographic Model of Temporal Recall

THE communication by Longuet-Higgins[1] has prompted me to suggest a different system of diffuse memory storage, which is based on holography like that described by Gabor[2] but differs from it in not requiring coherent repetitive vibrations Many systems of diffuse memory storage based on the interference principle are possible, holography being one The following requirements are essential

(1) The stimulus at each input point should produce a pattern of negative and positive values of some parameter over all the points in the storage area, which need not be a plane. (2) This pattern should be unique for the particular input point (3) Patterns from particular points are summated at the storage area according to the positive and negative values, producing a complex pattern (4) This complex pattern will represent uniquely a particular pattern of input stimuli at different input points, at various amplitudes (5) A suitable decoding system must be provided to convert a pattern in the storage area back to a corresponding pattern at the input area

A system of this kind can be made to have many of the properties found in holography The following are important (1) Many patterns in the storage area can be superimposed and decoded independently. (2) Ablation of large portions of the storage area will not drastically impair function (3) Part of the input pattern will serve as the code for extracting the remainder of the input pattern, for example, in holography the input pattern may be an object *A* plus a reference beam *a* *A* can be recovered by presenting *a*. Similarly, we can superimpose *B* with a different reference beam *b* and recover *B* independently We can also record object *C* together with a quite irregular reference beam *c* formed by the reflexion of light from an irregular object It does not have to be a plane mirror

We have here the elements of an associative memory If *D* plus *d* is recorded, sensory pattern *D* is recovered by putting in *d*, if *D* alone is recorded without *d*, then half of *D* will be the code for recovery of the other half

In the brain, the parameters which are summated at the storage area are excitation and inhibition The pattern is formed in the following way In the central nervous system, pulses are of constant amplitude. The intensity of a stimulus is represented according to the frequency of the pulses. The functional unit is a small group of synapses on the surface of a nerve cell, some of which carry excitatory and some inhibitory signals. These produce a transmitter substance and an inhibitor substance which enter the synaptic space and are summated there. When a sufficient excess of transmitter substance is built up, the cell fires and the substances disappear into the cell. Signals are thus summated at the functional unit in a way which is linear within certain limits.

Each neurone branches many times, ending in up to five thousand terminals which end as synapses on the surface of many cells. A simplified scheme showing three rows of cells is shown in Fig. 1*a*. Each dot represents a cell. The branches and synapses of two cells are shown and the others are assumed to be the same. One set of branches is shown in Fig. 1*b*. The figures represent the strength of the stimulus at each terminal. Some are inhibitory with a value of −1 and some excitatory with a value of +2. (In real life the inhibitory fibres have an internuncial neurone.) Assuming the simple additive relationship at the synapse, if a single cell in the first row of Fig. 1*a* is stimulated it is possible to deduce by simple arithmetic that the pattern of stimulation at the third row is as shown in Fig. 1*c*. The same information is shown in graphic form in Fig. 1*d*. The ganglion cells in the retina are already known to respond in this way—that is, with an excitatory receptive field surrounded by an inhibitory one.

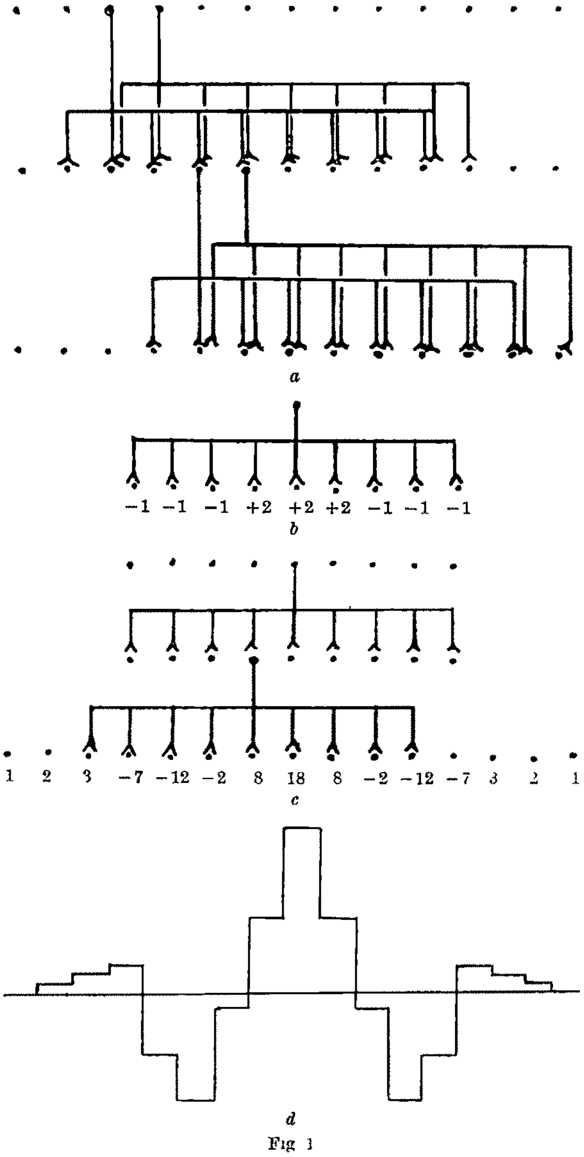

Fig. 1

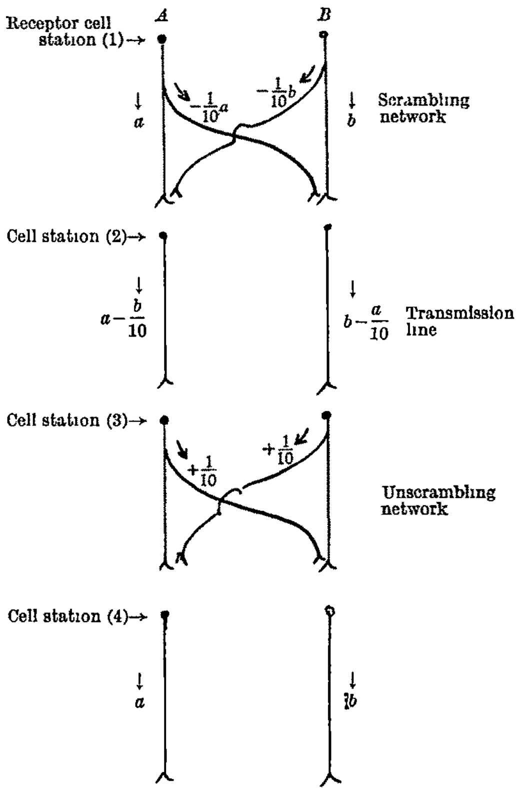

Fig. 2

In the brain the picture is more complex, with seven or more rows of nerve cells between the receptor and the cerebral cortex and branches from one cell are not confined to the next layer. The stimulation of a single receptor produces a complex pattern over the cortex and the pattern varies with each receptor.

For decoding, first consider Fig. 2, which shows two receptors A and B handling signals a and b. These pass to the second row of cells by one direct path carrying straightforward signals of value a and b and there is lateral inhibition of value, for example, of $-a/10$ and $-b/10$. Simple algebra shows that the decoding network is by a pair of excitatory side branches, as shown in Fig. 2.

Even for the most complex network, with many cells using some excitatory and some inhibitory branches, a decoding network could be designed by a suitable complementary arrangement. When making a computer with diffuse storage this could be designed, but in the brain it must be a random process. Cells which form the terminals corresponding to the decoded signal are self selected by a learning process. These cells which again hold the information in discrete form are widely scattered and are not contiguous. Most probably they are duplicated many times and there is considerable redundancy.

Information is stored in diffuse form in the synapses, which are changed by a signal passing through so that following signals are either decreased or increased. Either would serve as a basis for storage. It may well be that short term memory depends only on partial depletion of transmitter substance in the *boutons terminaux*. Long term memory involves a synthetic process and this may depend on a small increase in synaptic effectiveness over a large number of synapses in particular positions.

BOOK REVIEWS

BRITISH HYDROGRAPHY

The Admiralty Hydrographic Service 1795–1919

By Vice-Admiral Sir Archibald Day. (Ministry of Defence.) Pp. 378+13 plates. (London: H.M. Stationery Office, 1967.) 105s.

In 1885 Commander L. S. Dawson published *Memoirs of Hydrography*, a description of the growth of marine surveying in Britain from 1750 until the time when he was writing. Concentrating mainly on work done in the field, he gave a detailed account of surveys undertaken under naval auspices at home and abroad from the pioneering days of the Mackenzies and Captain Cook until the mid-nineteenth century when British ships had charted about three-quarters of the world's coastlines.

For some years after its foundation in 1795, the Hydrographic Office had little influence over surveys and it was not until Hurd's term of office (1808–23) that hydrographers began to have some say in choosing new projects. Gradually the department developed from its modest beginning as a clearing house for hydrographic material sent to the Admiralty by officers who took an interest in such work to the organization principally responsible for all surveys carried out by HM ships and for the production of charts which were available not only to the navy but to the general public.

When this happened the history of the Hydrographic Department and the progress of marine surveying became inseparable, and Admiral Day in *The Admiralty Hydrographic Service* has used the original departmental papers to produce a book specifically designed to supplement and continue Dawson's account, by describing the internal development of the Hydrographic Office, to which Dawson paid little attention, until 1884, and then carrying up to 1919 both the department's history and that of the surveys carried out under it. In this latter part of the book Admiral Day follows Dawson's original pattern, devoting a chapter apiece to the four hydrographers who held office between 1884 and 1919.

This chronological scheme precludes a sustained discussion of any single subject, but many themes run right through the book, notably the development of the concept of the department's role by successive hydrographers and their struggle to extend both its scope and its means. Notwithstanding repeated opposition from the Treasury in the form of cuts, as in 1851, and from the Navy Board, which was prone to object that the service "locks up" ships and men in its activities, it grew from the small office set up under Dalrymple in 1795 at an estimated cost of £470 per annum to an organization employing 350 people (on land) and spending nearly £150,000 per annum by 1919.

Admiral Day shows how, at the same time, the work of the surveyors changed, the broad sweeps of the early nineteenth century giving way to more painstaking coverage with techniques of increasing accuracy. The atmosphere of the service was so altered that in 1891 Wharton recommended increased pay for the crews of survey ships because they no longer had the "glamour of exploration" to compensate for their hard work. Increasingly their exploration was of a more scientific nature with contributions to many branches of science, especially oceanography and meteorology.

Admiral Day's book is much more than the story of the Hydrographic Department. It is a work of reference giving information both on its organization and on the many-sided activities which came under its control. It follows the progress made in producing Admiralty charts at all stages from the drawing board to their issue to the fleet and is illustrated with examples of the work of different periods, some of it of extreme beauty. It tells, with facts and figures, of what lay behind the exploits of the great surveyors of the nineteenth century which Admiral Ritchie described in *The Admiralty Chart* (1967), to which Admiral Day's book is, as he points out, complementary. *The Admiralty Hydrographic Service* is a most valuable addition to the growing number of books about the discovery of the oceans and its value would be enhanced if a reprint of Dawson's original *Memoirs* could be produced to accompany it.

MARGARET DEACON

ASTRONOMERS OF OLD

Their Majesties' Astronomers

A Survey of Astronomy in Britain between the Two Elizabeths. By Colin A. Ronan. Pp. 240+20 photographs. (London: The Bodley Head, 1967.) 30s. net.

The title of this book might suggest that it chronicles the activities of Astronomers Royal or governmental: the sub-title gives a better idea of its contents, though, of course, the survey could not possibly have been restricted to the work of British astronomers. Actually, it will serve to provide the general reader with a lucid account of the onward sweep of the science of the heavens during the past four hundred years.

A brief introductory chapter covers developments up to the mid-sixteenth century when the new Sun-centred cosmology began to inspire the English Copernicans, Recorde, Dee, Thomas Digges and the rest. Next, the urgent problems of navigation, hastening the foundation of the Royal Observatory, introduce the reader to Flamsteed and his immediate successors, to Harrison and his chronometer, and, through the beginnings of lunar theory, to Newton's achievements in celestial mechanics and in optics. Advances in the technique of telescope making lead on to the pioneer work of the Herschels and Lord Rosse in stellar and nebular astronomy. Following a chapter devoted to "The Neptune Scandal", Mr Ronan traces parallel developments in precise astronomy (revealing the phenomena of aberration and parallax) and in spectroscopy. He has been permitted to draw on the personal recollections and to consult the private papers of Mr William Christie, grandson of Sir W. H. M. Christie, the eighth Astronomer Royal. The concluding two chapters respectively survey the modern revival of interest in cosmology (in the fullest sense of the word) and endeavour to chart "The Way Ahead".

The reader of this book will encounter certain imprecisions. The stars do not all exhibit their maximum aberrational displacements northward or southward at the same time of year (page 139). The point about Gill's determination of the solar parallax at Ascension Island was not that he had "a base-line of some fourteen hundred miles to Greenwich", but that a calculable base-line was marked out by the Earth's rotation and orbital motion between evening and morning observations (page 153). The stellar distance cited on page 151 requires three more ciphers. There are not 86,000 but 86,400 sec in one day (page 198). Samuel Molyneux, Bradley's colleague, is confused with his father William (page 93), "the elder Cassini" is confused with his son Jacques (page 137). Lockyer's first name was Joseph, not John (page xi and facing page 176). There are, indeed, besides obvious misprints, many mistakes in the spelling and initialling of proper names in both text and index, and several wrong dates. The book requires, and deserves, a thorough revision before proceeding to a second edition.

A. ARMITAGE

HALLUCINOGENS

The Hallucinogens

With a Contribution by T Weckowitz By A Hoffer and H. Osmond Pp ix+626 (New York Academic Press, Inc , London Academic Press, Inc (London), Ltd , 1967) 200*s*

THE hallucinogens, almost totally unknown twenty years ago, currently enjoy a sinister notoriety engendered by their social misuse This has tended to obscure the most valuable contribution they have made to neurological science A study of their mode of action has led to advances in biochemistry and pharmacology as well as throwing what little light there is on the biochemical basis of schizophrenia They have also been used widely in psychotherapy and form an interesting facet of pharmacoanthropology This book surveys all these aspects of the known hallucinogens, covering the literature to 1965 The following fields are covered origins, chemistry, biochemistry, pharmacology, neurophysiology, psychology, clinical implications and use and anthropology. Naturally some of these are dealt with more fully than others, particularly detailed accounts are given of the psychological and clinical effects of these drugs and interesting details of the use of the plants from which they are derived by various cultures

Some 150 pages are devoted to adrenochrome and its relatives The controversies which have raged over this compound are described by the authors, who have long battled in defence of the "adrenochrome theory" of schizophrenia Some of the bitterness of this dispute is reflected in their comment "adrenochrome, at one time, became a dirty word".

This involves three problems: (1) whether adrenochrome is a hallucinogen, (2) whether it occurs *in vivo*, and, if so, (3) whether it plays any part in the biochemical lesion of schizophrenia Reports on the psychological effects of adrenochrome have been conflicting, but a recent double-blind study carried out in Czechoslovakia by Grof *et al* [1] supports the claim that it produces a psychotomimetic reaction.

In considering the question as to whether adrenochrome actually occurs *in vivo*, Hoffer quotes twenty authors who found "fluorescent derivatives of adrenaline in body fluids or tissues". However, if one refers to these sources quoted, one finds that there has been some confusion for example, (i) Utevskii *et al* [4] report that whereas brain contains "substances which exhibit the properties of intermediate products of quinoid oxidation of catechol amines" they go on to state "adrenaline, adrenochrome or adrenolutin was not detected" Fischer and Landtsheer[5] injected the adrenochrome themselves to trace its metabolism, and Bacq *et al* [6] and Goldenberg *et al* [7] did not detect any adrenochrome at all, but merely used the Von Euler method of estimating adrenaline by converting it themselves to adrenochrome Fischer and Lecomte[8] curiously quote Bacq *et al* [6] as stating that 10–20 per cent of the injected adrenaline was excreted as an indolic compound—a fact not mentioned in this paper Green *et al.*[9] did not actually detect anything but merely suggested a conversion of adrenaline to adrenochrome as a hypothesis to explain the inhibitory action of ferritin on the action of adrenaline on capillaries Gershenovich *et al* [10] found adrenochrome only in brains of rabbits dying of oxygen poisoning (exposed to 3 5–6 atmospheres pure oxygen) Three other references were untraceable I did not consult the rest Moreover, Hoffer does not quote any of the authors who failed to find adrenochrome in the blood, notably Axelrod[2] Thus the matter remains quite unresolved It is still possible that adrenochrome or one of its relatives may be formed in the brain in schizophrenia, although there is no direct evidence to support this The indirect evidence presented is not very convincing In our present state of ignorance concerning the biochemistry of schizophrenia it would, however, be unwise to be dogmatic in any direction But I would urge in general that workers in this field should recall Popper's dictum that a theory should be tested with the direct aim of trying to refute it Only by surviving such tests can a theory become valid

The authors include an attack on the "double-blind" methodology in trials of psychotropic drugs. Although there is much to be said for their criticism of much of the methodology in this field, I remain convinced that the "double-blind" precaution remains quite essential and the failure to observe it has led many investigators wildly astray J R SMYTHIES

BIOLOGY OF THE UTERUS

Cellular Biology of the Uterus

Edited by Ralph M Wynn. Pp xi+524 (Amsterdam North-Holland Publishing Company, New York Appleton-Century-Crofts, 1967) 180*s*.

RESEARCH into the anatomy, physiology and biochemistry of uterine and placental function has increased very considerably during recent years So far, however, few textbooks have attempted even a limited survey of the progress that has been made Ralph Wynn has brought together fourteen other authors in a very comprehensive review of what he has chosen to call uterine cellular biology This has enabled him to concentrate attention on the many different aspects of normal uterine function

Dr S R M Reynolds in a thoughtful opening chapter reviews many of the important advances in the field of reproductive physiology and morphology during the past 40 years He sets the standard for the excellent chapters that are to follow He rightly claims "that so large has this field of study become that today a person must of necessity become a student in, rather than of, the subject"

Jack Davies reviews the embryology of the uterus both in the human and other animals Elizabeth Ramsey describes the vascular anatomy of the uterus, while John Morris discusses the vascular physiology

The genetic, biochemical and hormonal mechanisms in the regulation of uterine metabolism are considered in reasonable detail by Kenneth McKerns This chapter includes a consideration of hormone biosynthesis in the ovary and human placenta as well as the steroid relationships between the human foetal adrenal and placenta These, in fact, are the only aspects of placental metabolism that are discussed, but in a book devoted essentially to the uterus this is acceptable.

The only British contributors to this symposium are Dorothy Needham and Catherine Shoenberg from Cambridge They provide a very well documented account of the biochemistry of the myometrium listing more than 200 references Indeed, most chapters include a very up to date and a very complete number of references Other chapters are devoted to oestrogens, nucleic acids and protein synthesis in uterine metabolism, decidualization, the ultrastructure of the myometrium, the ionic basis of electrical activity in uterine smooth muscle, and hormonal regulation of myometrial activity and its clinical applications

This book should prove invaluable to all those who are interested in reproductive physiology and biochemistry

Concentrated within its 499 pages is a wealth of biological scientific detail. Perhaps other writers could be encouraged to publish a similar synthesis of important biological information. In particular, there is a considerable need for a comparable book devoted to the placenta. Meanwhile, Ralph Wynn has set a very high standard for any who may care to follow his method of presentation.

N. F. MORRIS

TOOTH BIOLOGY

Structural and Chemical Organization of Teeth

Vol. 1. Edited by A. E. W. Miles. Pp. xv+525. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 220s.

THERE can be little doubt that the first volume of this two volume treatise contains much of interest and significance to biologists in general as well as to dental research workers. The reason for this probably lies in the fact that most of this volume deals with dental development which exhibits many fundamental processes of biology such as induction, morphogenesis and mineralization. The relationship between the neural crest cells and dental development, not yet fully understood but well reviewed in this volume, provides a good example of how things dental have application to the wider realms of biology.

It is a little more problematical to assess the value of this book to the dental research worker. Its encyclopaedic character means that those chapters dealing with subjects where advances have been rapid are to some extent dated. The initial overtures to the contributors were made some five years ago and, although the editor has tried, by the addition of addenda, to keep abreast of recent developments, advances in some fields have been so rapid as to make this an impossible task. This criticism must not be allowed, however, to detract from the value of the volume as a whole. It provides an excellent source of reference and this alone justifies the effort that has gone into its production. I am, however, a little perturbed by the cost of the volume. Together with its companion this exceeds twenty pounds, which virtually limits its sale to libraries. Whether large, expensive, multi-author treatises are the best means of collecting and sifting information can be questioned. The eleven chapters in this volume could equally well have been published in the form of separate monographs at a cost allowing individual purchase over a period of time. Even so, the contents of this book needed to be published and the editor, together with the publishers, has succeeded magnificently in what must have been no mean feat of production.

A. R. TEN CATE

GENES IN ACTION

The Message of the Genes

By Navin Sullivan. Pp. 198. (London: Routledge and Kegan Paul, Ltd., 1968.) 25s. net.

THE past two decades have witnessed enormous advances in our understanding of what genes are and how they function. It is not unimportant that the layman should have an opportunity of learning about these developments. After all, it is he who eventually finances research, the discoveries made will, no doubt, have an ever increasing impact on the society in which he lives and, if he is able to share in some of the excitement which research generates, so much the better. Mr Sullivan's book is not for the specialist.

The Message of the Genes opens with a description and interpretation of Mendel's experiments on the inheritance of certain traits in peas. This is followed, in the second chapter, by a brief account of chromosomes and the construction of genetic maps. The next two chapters describe the chemical components of which cells are made, the function of proteins as enzymes and hence why nucleic acids, as the information carriers, are so important. This lays the foundation for the next six chapters, which are concerned with modern molecular biology: how genetic information is duplicated and how it is expressed. Mechanisms for gene expression begin the final chapter, which concludes with a short section on memory.

In all this Mr Sullivan presents the relevant experiments with a fresh enthusiasm; far from being a textbook, this account is written in an engaging style which will draw the reader on to follow the line of thought or the connexion between seemingly unrelated observations. This is accompanied by the occasional aside in which the author relates how the physical difficulties of solving the problem were overcome by the scientist, or the excitement of the meeting at which the results were first presented.

The specialist may find several unimportant errors in the book: the structures of ammonium cyanate and urea on page 42 are incorrect, the legend to Fig. 24 gives the wrong impression of the position on an *s*RNA molecule to which the amino-acid is attached, and a couple of people are credited with work which was done by others. A reader with a small knowledge of chemistry might have expected the book to be more chemical in outlook, particularly those sections which describe the biosynthesis of proteins and nucleic acids. These criticisms should not deter the lay reader. The book, the message of which comes across as a clear and lucid presentation, is to be recommended at its modest price.

M. S. BRETSCHER

EXPERIMENTS IN BEHAVIOUR

Experiments in Animal Behaviour

By Marguerite D. Hainsworth. Pp. x+206+8 plates. (London: Macmillan and Co., Ltd.; New York: St Martin's Press, 1967.) 35s.

TEACHERS at all levels have learned by bitter experience the problems of class experiments in behaviour. They usually require a long time in which to carry them out, the observations only producing a pattern which demands explanation after numerous notes on factors which may or may not be crucial have been made. Animals are wayward creatures liable to make just those reactions which theory finds it hardest to explain. Miss Hainsworth attempts to come to the teachers' help by drawing together a number of possible experiments on the behaviour of animals from all parts of the animal kingdom. She does many a service in this, for not only does she continually pose questions the answers of which lie in the observations made but she also harps on the need for quantitative results. Indeed, criticism of work on behaviour by other scientists is frequently that it is uncritical in its methodology, but this book endeavours to instil into the student a sense of the importance of questioning not only what he is studying but also how he is studying it.

Part of the point of the book is that it shows that any part of an animal's activities is worth studying in the context of behavioural investigations. It is not necessary to look at courtship, striking though this essential behaviour is and despite the amount of space given to it in the literature, how an animal moves may be closely observed and analysed, or its food preferences, or its reaction to light or a slope. These details of behaviour, however, may too easily be considered minutiae by a student, not worthy of great attention and quite unexciting. Successful experiments, in terms of class morale, are ones that stand a good chance of working in the sense that they produce discussable results. But great faith is needed to carry out very many of these suggestions and I cannot help wondering whether some of them are as useful as they appear But it must be admitted that what may be successful with one class is not necessarily so with another, the user makes his own selection

The experimental details are often good, for example, it is pointed out that the gas supply in some districts may no longer contain the respiratory poisons so useful in anaesthetizing protozoa, yet the important warning for these times that glassware used for protozoa must not be washed in detergent is not there The importance of identifying an animal and the use of comparative studies are both stressed, yet inexplicably all sea anemones are lumped together as if their behaviours would be the same. And in her desire to hang the experiments on a framework of theory, the author makes some remarkable statements, surely, for example, the molluscs can hardly be called an "aberrant" group ? It is perhaps misleading to suggest that the reaction of *Hydra* to glutathione has something in common with the reactions of minnows to alarm substances Although a chemical stimulus is involved in both, the behaviour evoked is quite different and almost certainly the receptors involved bear little likeness to each other

Nevertheless, this book contains many useful ideas which should stimulate teachers to try again with experimental work in behaviour They will not lack direction for their theoretical reading, for Miss Hainsworth supplies a good list of selected references The book is attractively produced and, apart from the transposition of two legends, the illustrations are clear and informative

J D Carthy

WATCHING BIG GAME

A Field Guide to the National Parks of East Africa

By John G Williams Pp 352+32 plates (London William Collins, Sons and Co , Ltd , 1967) 45*s* net.

This book has three sections which describe the wild life areas, their mammals and their rarer birds

Sixty faunal areas covering about 50,000 square miles are discussed Places of ornithological interest such as the Uganda forests are detailed, while some areas like the 11,000 square mile Selous are treated briefly and yet others, Ankole, for example, although faunistically interesting, are scarcely mentioned However, due emphasis is placed on such new and exciting parks as the Ruaha, Kidepo and Meru Accompanying these descriptions are comprehensive check lists of birds and mammals with maps and details of communications, which will be useful to tourists when planning their itineraries

The mammal section occupies a sixth of the book and is disappointingly brief about such conspicuous creatures The larger mammals and bats, of which the author is particularly knowledgeable, are emphasized while Murids, with their attendant taxonomic problems, are dismissed as "seldom seen unless specially searched for "

Concise descriptions of the mammals include details of their distribution and habitat, but I would also welcome descriptions of their seasonal movements and, for night identification, their calls Some of the information in the literature on demography, nutrition and ethology would also be relevant Such information when given is occasionally misleading, for example, we are told, without further qualification, that the "hippo" is 14 ft long

Why is far more space given to the rare Uganda cormorant than to elephants, despite the latter's importance in many park ecosystems today ? There is, for instance, no mention of their huge mobile ears as useful characteristics for distant identification or of the Congo race found in the Semliki Valley The answer lies partly in John Williams's years of experience in the Coryndon Museum, Nairobi, and his intimate contact with the living material while on safari, from which he has acquired unparallele knowledge of their taxonomy

His taxonomic approach is essential in the section o rarer birds It is here that the Peterson method indicatin diagnostic characters on the plates by pointers is mos valuable The plates drawn by Rena Fennessy, famou for current wildlife issues of East African postage stamp although superb would benefit from a scale This sectio supplements the author's previous field guide to th commoner birds, to which there are abundant cross references and without which visiting ornithologists wi be lost

This book will require regular revision to keep pac with scientific work, new areas and sightings such a greater kudu and oryx now confirmed from the Kidep or to delete species like the Queen Elizabeth Park huntin dog

Our changing knowledge is emphasized by an exampl from the area with which I am most familiar Ishash lions do not climb trees so much to see over the grass which is in any case short, but to avoid flies and heat

This then is a guide for the taxonomically orientate tourist and the ornithological enthusiast I hope that i will stimulate others, including East African school children and potential ecologists, to a greater awarenes of these little known areas Christopher R Field

OBITUARIES

Professor J H. Taylor

James Haward Taylor, AM, PhD, FGS, FRS, who hel the chair of geology at King's College, University o London, was one of Great Britain's most distinguishe geologists His death by drowning while engaged on underwater research in the Seychelles is a sad loss to th science

Educated at Clifton College and King's College, London, he obtained a Henry Fellowship to Harvard in 1933, returning to take up an appointment to HM Geological Survey From this he was appointed professor of geology at his old college in 1949

His initial interest was in igneous rocks, which he studied in Leicestershire and the Isle of Man His work at Harvard, on the Little Belt Mountains, Montana, led him to a study of mineralization, while his early work with the Geological Survey in the west Midlands stimulated his interest in the sedimentary formations These interests coalesced when, during the Second World War, he was engaged on the study of the Northamptonshire iron-ore field He made the petrology of these ores his special study, and his memoir on them has become a standard work on the subject At the same time he maintained an active interest in their field occurrence, and with S E Hollingworth and G A Kellaway established the importance of periglacial superficial movements in their disposition This in turn led to a study of the Pleistocene sequence and the geomorphology of the area

A student mapping project in the central Weald revived his interest in these sediments, and his studies of this sequence are among his latest publications He retained his interest in economic ores, however, extending his work to Broken Hill, Rhodesia He was greatly interested, through earlier studies of Jurassic limestones in the English Midlands, in the genesis of these rocks, and in 1963 initiated a project to investigate recent limestone formation on the Seychelles Banks Some of his students' work on this had been published, and the project contained the promise of exciting contributions in this new and expanding field He travelled widely, in Europe, Africa and North America, and had a wide and varied knowledge of geology outside his special interests

All Professor Taylor's work was marked by a meticulous attention to accuracy and to scientific discipline He set himself the very highest standards of investigation and exposition He applied the same conscientiousness to his numerous other duties, he served on the councils of the Geological Society, the Geologists' Association, the Mineralogical Society and the Institute of Mining and Metallurgy, being president of the last two, he was elected to a fellowship of the Royal Society in 1960, served on its council and became chairman of the British National Committee for Geology He was a member of the Natural Environment Research Council and of the Iron and Steel Federation and the British Ceramic Research Association During the past year he presided over the meetings of the International Sedimentological Congress at Reading and Edinburgh All these, and his many other duties, he carried out with a zeal and an efficiency which were a constant source of amazement to all who knew him

His public manner, apparently controlled and urbane, concealed a deeply shy and reserved nature Despite this, however, all who were in contact with him immediately sensed a warmth of understanding Unfailingly courteous, his time and energies were always at the service of his colleagues He enjoyed the respect of all, and leaves a multitude of friends J E PRENTICE

Dr P. J. du Toit

DR P J DU TOIT, who died in Pretoria on November 13, 1967, at the age of 79, was one of South Africa's greatest men of science—first in the role of a brilliant young veterinary research worker, then as Dean of the Faculty of Veterinary Science at the Transvaal University College of South Africa, where he succeeded Sir Arnold Theiler in 1927, and later as Director of Veterinary Services in South Africa (1927–48), a responsibility which included guiding the destinies of the world-renowned Veterinary Research Institute at Onderstepoort

While the careers of many lesser men may have ended there, at retirement, du Toit went on with characteristic enthusiasm and stamina to become the second President of the South African Council for Scientific and Industrial Research (CSIR) in 1951, succeeding Sir Basil Schonland Later (1951–60) he was appointed President of the Scientific Council for Africa South of the Sahara (CSA)—a non-governmental body that has since become a victim of political change in Africa During these years, du Toit guided the activities of CSA at numerous meetings of the Commission for Technical Co-operation in Africa South of the Sahara (CCTA) held in East, Central, West and southern Africa

Du Toit's academic qualifications included a BA (Hons); PhD (with honours) from Zurich University, and a doctorate in veterinary science, with honours, from Berlin He held six honorary doctorates at the time of his death, four from South African universities which recognized his outstanding contribution to science in Africa, and one each from the universities of Utrecht, Holland and Glasgow

Du Toit was a Fellow of the Royal Society and belonged to twelve scientific societies all over the world He served on many commissions, enquiring into education, veterinary science, agricultural science, medicine, museums and so on, and represented South Africa at many international conferences He wrote more than 140 publications

His early interest during the First World War, when he was allowed to continue his research in Germany despite the fact that he held a British passport, was leukaemia in cattle He received a doctorate in veterinary science for this work from the University of Berlin and later collaborated with Professor P Knuth on tropical veterinary problems He was co-author with Knuth of a standard textbook (in German) on tropical diseases in domestic animals

Du Toit returned to South Africa in 1919 to carry on with the fundamental research into lamsiekte (bovine botulism) begun by Sir Arnold Theiler This was to have far-reaching results in the development of the study of mineral deficiencies By 1928 he had focused his attention on protozoology and virus diseases as professor at the Transvaal University College of South Africa A year before, he had visited Nigeria and reported on veterinary matters there at the request of the Colonial Office in the United Kingdom

Despite growing administrative burdens, du Toit's research continued in earnest until after he retired as Director of Veterinary Services of the South African Department of Agriculture, and Dean of the Faculty of Veterinary Science, University of Pretoria, in 1948 A cross-section of his publications reveals interests ranging from rinderpest to iodine in the nutrition of sheep, from problems of immunity in animal diseases to studies of the mineral content and feeding value of natural pastures in South Africa

It is difficult to write an appreciation of a scientist such as P J du Toit, for he would have been the first to contend that the praise was undeserved and his achievements were mainly due to the efforts of his colleagues He will be remembered as an outstanding administrator with a mind comprehensive in its grasp of things and simple and precise in its setting out of a problem In addition to his scientific and academic responsibilities he gave much time to public work of various kinds, including active membership of the South African Historical Monuments Commission

As a personality, he will be remembered for his keen sense of humour and charming companionship He was in great demand as a raconteur and after-dinner speaker, accomplishments which earned him the affectionate sobriquet "P J " He never flaunted his own achievements nor underrated the work of others S M NAUDÉ

Professor G. Z. Dimitroff

GEORGE Z DIMITROFF, emeritus professor of astronomy at Dartmouth College, Hanover, New Hampshire, and former superintendent of the Harvard Observatory, died on January 1 at his home in Hartland, Vermont, at the age of 66 He had been a member of Dartmouth's astronomy department for twenty years before his retirement in June 1966

A native of Svistove, Bulgaria, Dimitroff graduated from the University of Boston in 1927 and took his MA and PhD degrees at Harvard He taught physics at Colorado State College and astronomy at Harvard and Radcliffe

For five years before he went to Dartmouth, Dimitroff was superintendent of the Harvard Observatory where he helped to build some of the largest Schmidt cameras in existence before that at Mount Palomar was built He advised the Mexican government about the building of their astrophysical observatory at Puebla, and was co-author of a book on telescopes and accessories

For hundreds of Dartmouth undergraduates Astronomy 1 and Professor Dimitroff were synonymous In addition to this introductory course in stellar astronomy and the astronomical universe, popularly known as "stars", he also taught more advanced courses in astrophysics and observational astronomy. His open house "Evening with the Stars" at the Shattuck Observatory gave pleasure to many Hanoverians, young and old

As a commander in the US Navy in the Second World War, Dimitroff undertook a variety of scientific missions in Europe and Japan, including studies of optical developments there On leave from Dartmouth in 1956, he surveyed astronomical developments in Europe and the Middle East, and at that time was scientific liaison officer with the US embassy in London He went to Russia in 1958 as a member of the International Astronomical Union and returned there in 1963 as part of a world tour of observatories Impressed with Russian scientific advances, he predicted that in twenty years Russia would be the leading scientific nation

University News :

Bristol

Dr M A Epstein, reader in experimental pathology in the Middlesex Hospital Medical School, has been appointed professor of pathology in succession to Professor T F Hewer

Manchester

Dr K R Parthasarathy, at present reader in probability theory in the University of Sheffield, has been appointed to the chair of mathematical statistics

New South Wales

Professor P T Fink, formerly P N Russell professor of mechanical engineering in the University of Sydney, has been appointed professor of mechanical engineering and head of the School of Mechanical and Industrial Engineering

Reading

Dr E H Roberts, lecturer in horticulture in the Department of Botany, University of Manchester, has been appointed professor of crop production

Salford

Dr R R Birss, at present senior lecturer in physics, University of Sussex, has been appointed to a second chair of physics in the Department of Pure and Applied Physics

Appointments

Dr R L Mitchell, at present deputy director of the Macaulay Institute for Soil Research, has been appointed director of the institute in succession to Dr A B. Stewart

Announcements

Ege University at Bornova, Izmir, Turkey, is setting up a Natural Science Museum which will be attached to the Faculty of Science It is hoped that the proposed six halls, each 250 square metres, will be finished by the end of 1970. At the preliminary stage of organization of the museum the Dean, Professor Dr Yusuf Vardar, and his staff are seeking advice from various museums in the world on organization, administration and activities They would now appreciate help from any other institution in the form of publications covering methods of collection, preservation, maintenance and registration of exhibits Any material (zoological, botanical or geological) which can be donated would also be greatly appreciated

The following have been elected officers of the American Crystallographic Association for 1968. *President*, Dr S C Abrahams, Bell Telephone Laboratories, Murray Hill, New Jersey; *Vice-President*, Dr W C Hamilton, senior chemist at Brookhaven National Laboratory, Upton, New York

Dr Sol Spiegelman, professor of microbiology at the University of Illinois, has been awarded the 1968 Bertner Foundation Award for his work involving replication of genetic material in controlled laboratory conditions.

Meetings

Modern Techniques in Food Analysis, March 19, Grimsby College of Technology (Head of Science Department, College of Technology, Nun's Corner, Grimsby, Lincs)

Training of Food Scientists and Technologists, April 4–5, Grimsby College of Technology (Head of the Science Department, College of Technology, Nun's Corner, Grimsby, Lincs).

Turbulence of Fluids and Plasmas, April 16–18, New York City (MRI Symposium Committee, Polytechnic Institute of Brooklyn, 333 Jay Street, Brooklyn, NY 11201)

Computer-based Information Retrieval Systems, April 18–19, Liverpool (Bernard Houghton, School of Librarianship and Information Work, College of Commerce, Department of Professional Studies, Tithebarn Street, Liverpool 2)

Mechanical Design, May 6–10, University of Bradford (The Registrar, University of Bradford, Bradford 7)

Cryogenics Engineering, May 7–10, Brighton (Conference Secretary, ICEC 2, "Cryogenics", 32 High Street, Guildford, Surrey)

Surging Glaciers, June 6–8, Banff (C M Lockwood, Assistant Director, Department of Extension, The University of Alberta, Edmonton, Alberta)

Canadian Botanical Association, June 11–14, Ontario (D R Lindsay, c/o Canadian Botanical Association, Lakehead University, Port Arthur, Ontario)

Corrosion and Protection of Pipes and Pipelines, June 12–14, Earls Court (Technical Exhibitions Ltd, 3–4 Clements Inn, London WC2)

Third Congress of the European Society of Ophthalmology, June 18–21, Amsterdam (The Secretariat, c/o Holland Organizing Centre, 16 Lange Voorhout, The Hague, The Netherlands)

The Solar Terrestrial Environment, July 10–12, Sheffield (Miss G M White, Department of Applied Mathematics and Computing Science, The University, Sheffield).

Organic Geochemistry, September 16–18, Amsterdam (Dr P A Schenck, Secretary of the Organizing Committee, 4th International Meeting on Organic Geochemistry, Volmerlaan 6, Rijswijk (Z H.), The Netherlands).

Mass Spectroscopy Group meeting, September 16–18, University College, London (Secretary, Mr R. M Elliott, GEC-AEI (Electronics), Ltd, Scientific Apparatus Division, Barton Dock Road, Urmston, Manchester).

Electronics Design, September 23–27, University of Cambridge (The Conference Department, Institute of Electrical Engineers, Savoy Place, London WC2).

Stresses in Composite Materials, September 25–27, College of Aeronautics, Cranfield (The Meetings Officer, The Institute of Physics and the Physical Society, 47 Belgrave Square, London SW1).

Cellular and Humoral Mechanisms in Anaphylaxis and Allergy, October 3–5, Toronto (Professor Henry Z Movat, Department of Pathology, University of Toronto, 100 College Street, Toronto 2, Canada)

Astronautical Congress, October 13–19, New York (Miss Mireille Gérard, American Institute of Aeronautics and Astronautics, 1290 Avenue of the Americas, New York, NY 10019)

Meeting of the Clay Minerals Society, October 14–17, Indiana University (Dr John B Droste, Department of Geology, Indiana University, Bloomington, Indiana 47401)

Crystallography, August 7–27, 1969, Roswell Park Memorial Institute, Buffalo (August 7–12), State University of New York at Stony Brook (August 14–21), Stony Brook campus and Brookhaven National Laboratory, Long Island (August 23–27) (Eighth International Congress of Crystallography, Congress Office, State University of New York, Stony Brook, Long Island, New York).

Erratum In the communication "Stimulative Vaporization of Phenylmercuric Acetate by Mercury-resistant Bacteria" by R Tonomura *et al* (*Nature*, 217, 646, 1968) the fresh culture medium (line 3, paragraph 4) contained 2,000 μg of inositol and 400 μg of nicotinic acid as well as the components listed

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, February 26

University of London (in the Anatomy Theatre, University College London, Gower Street, London, WC1), at 5 30 p m —Professor A W Merrison "The Science and Engineering of Elementary Particle Physics" (further lectures on March 4 and 11) *

Tuesday, February 27

Royal Statistical Society (Medical Section) (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, WC1)—Dr I Sutherland "When was the Great Plague ?"

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 2 30 p m —Colloquium on "Developments Towards a Computer-Based Information Service in Physics, Electrotechnology and Control"

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W1), at 4 p m —Symposium on "Cement Automation"

Imperial College of Science and Technology (in Lecture Theatre A, Department of Mechanical Engineering, Exhibition Road, London, SW7), at 5 30 p m —Professor W S Elliott "The Computer—Master or Servant ?" (Inaugural Lecture)

Royal Institution (at 21 Albemarle Street, London, W1), at 5 30 p m —Professor Ronald King "Metals" (Lecture for Sixth Form Boys and Girls from Schools in London and the Home Counties To be repeated on February 28, March 5 and 6)

University of Aston in Birmingham (at Gosta Green, Birmingham, 4), at 5 30 p m —Professor E J. Davies "The Challenge of Electrical Machines" (Inaugural Lecture)

University of London (at the Institute of Child Health, Guilford Street, London, WC1), at 5 30 p m —Professor S Cohen "Structure and Biological Properties of Immunoglobulins" (Fourteenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)*

University of London (in the Engineering Theatre, University College London, Gower Street, London, WC1), at 5 30 p m —Professor E H Brown "Man, the Geomorphological Process" (Inaugural Lecture) *

University of London (at the Institute of Archaeology, 31–34 Gordon Square, London, WC1), at 5 45 p m —Dr C F A Schaeffer (Paris) "Ras Shamra—Ugarit" (further lecture on February 29) *

Wednesday, February 28

Royal Aeronautical Society, Agricultural Aviation Group (at 4 Hamilton Place, London, W1), at 10 a m —All-day Meeting on "Operational and Safety Aspects of Agricultural Aviation"

Royal Institution, History of Science Discussion Group (at 21 Albemarle Street, London, W1), at 1 p m —Professor Robert Siegfried (University of Wisconsin) "Humphry Davy's Attitude to the Uses of Science" *

Society of Chemical Industry, Food Group and the Microbiology Group (at the School of Pharmacy, Brunswick Square, London, WC1), at 2 30 p m —Meeting on "Microbial Problems of Food Handling Equipment"

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5 30 p m —Dr E. T Hall "Measurement as an Aid to Archaeological Research"

Society of Apothecaries of London, Faculty of the History of Medicine and Pharmacy (at Apothecaries' Hall, Blackfriars Lane, London, EC4), at 5 30 p m —Sir George E Godber "General Practice, Past and Present" (Monckton Copeman Lecture)

Institution of Electronic and Radio Engineers, Communications Group (at 9 Bedford Square, London, WC1), at 6 p m —Mr R Gibson and Mr S M Edwardson "Ultrasonic Delay Lines and their Uses in Television"

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Dr J G Wistreich "Impact of Automation of Steel Manufacture on Plant Design" (John Player Lecture)

Society for Analytical Chemistry, Thin-Layer Chromatography Group (at "The Feathers", Tudor Street London, EC4), at 6 p m —Discussion Meeting on "Radiometric Microanalysis Employing Thin-Layer Chromatography".

University of London (at the Institute of Archaeology, 31–34 Gordon Square, London, WC1), at 6 p m —Miss E Vollans "Sources of Maritime Archaeology—Trade and Ports in Britain" *

Thursday, February 29

Royal Society (at 6 Carlton House Terrace, London, SW1), at 10 30 a m —Discussion Meeting on "Science and Technology of Aerosol Pollution in Modern Society" organized by Professor A R Ubbelohde, FRS, and Professor T M Sugden, FRS

University of London (in the Anatomy Theatre, University College London Gower Street London, WC1), at 1 20 p m —Mr D H Girmes "Is Logic Absolute and Complete ?"*

University of London (at Imperial College, London, SW7), at 1 30 p m —Mr Pat Carpenter "Art and Science VIII—Art and Science Now—the Possibilities of Convergence" *

Fertiliser Society (at the Geological Society, Burlington House, Piccadilly, London, W1), at 2 30 p m —Mr W C Weber and Mr I S Mangat "The Production of High Nitrogen NPK Granular Fertilisers"

Institution of Civil Engineers Hydrological Group (at Great George Street, Westminster, London, SW1), at 5 30 p m —Report on Leningrad Symposium on Floods and on Soviet hydrological research introduced by Mr M Mansell-Moullin and Mr J C Rodda (Informal Discussion)

University of London (at the Institute of Child Health, Guilford Street, London WC1), at 5 30 p m —Dr N A Mitchison "Recognition of Antigen" (Last of fifteen lectures on "The Scientific Basis of Medicine", organized by the British Postgraduate Medical Federation)*

Institution of Mechanical Engineers, Process Engineering Group (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion Meeting on "Development in Desuperheated Techniques"

Friday, March 1

West Cheshire Central College of Further Education (at Carlett Park, Eastham, Wirral, Cheshire)—Symposium on "Advances in Polarography"

Linnean Society of London (at Burlington House, Piccadilly, London, W1), at 10 55 a m —Symposium on "The Experimental Taxonomy of Flowering Plants"

Royal Institution, Photochemistry Discussion Group (at 21 Albemarle Street, London, W1), at 1 p m —Mr M B Ledger "Photoreactions in Water" *

Institute of Rural Life at Home and Overseas (at Friends International Centre, Courtauld House, Byng Place, London, WC1), at 1 15 p m —The Rev Merfyn Temple "Problems of Development for Rural Communities in Zambia" *

University of London (at the Royal Postgraduate Medical School, Du Cane Road, London, W12), at 4 p m —Dr C N Armstrong "The Diagnosis of Sex" *

Institution of Electrical Engineers (at Savoy Place, London, WC1) at 5 30 p m —Mr H B Williams and Mr S C Chu "Computer Solution of e h v Underground Cable Cooling Problems"

Society for Analytical Chemistry (at the County Hall, Durham City), at 5 30 p m —Annual General Meeting, followed by Mr L J Clark "North Sea Gas"

University of London (at Queen Elizabeth College, Campden Hill Road, London, W8), at 5 30 p m —Professor L Hough "The Chemical Architecture of Carbohydrate Molecules" (Inaugural Lecture)

Royal Institution (at 21 Albemarle Street, London, W1), at 9 p m —Dr Anne McLaren "Life Before Birth—the First Few Days"

Saturday, March 2

Inner London Education Authority (at the Horniman Museum, London Road, Forest Hill, London, SE23), at 3 30 p m —Zoe, Lady Hart Dyke "Silk Farming in England" *

Monday, March 4

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 10 a m —Colloquium on "Pulsed Code Modulation"

University of London (at the Royal Postgraduate Medical School, Du Cane Road, London, W12), at 4 p m —Professor R D Girdwood "Folic Acid Deficiency" *

Institution of Civil Engineers (at Great George Street, Westminster, London, SW1), at 5 30 p m —Informal Discussion on "The Organization of the Port Planning Team and the Role of the Engineer" introduced by Mr J E G Palmer

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5 30 p m —Discussion Meeting on "The Need or Otherwise for Suppression of Harmonics Generated by Convertor Equipment" opened by Mr H J Sheppard

University of London (at the Royal Free Hospital School of Medicine, 8 Hunter Street, London, WC1), at 5 30 p m —Docent Annica Dahlström (Stockholm and Goteborg) "Monoamine-containing Neurones in Mammals I Monoamine-containing Neurones in Mammals as Studied by Fluorescence Microscopy" *

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion Meeting on "Designing Components Subjected to High Surface Pressure"

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W1), at 6 p m —Mr F W. Hyde "Progress in Radio Astronomy"

Society of Chemical Industry, London Section (joint meeting with the Chemical Engineering and Heavy Organic Chemicals Groups, at 14 Belgrave Square, London, SW1), at 6 30 p m —Sir Kenneth Hutchison, CBE "New Sources of Natural Gas for Britain" (Jubilee Memorial Lecture)

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Lecturer in the Laboratory of General Physiology in the School of Biology—The Registrar, The University, Leicester (February 28)

Lecturer or Assistant Lecturer (with good academic qualifications in sociology, teaching experience and an interest in the sociology of education) in Education—The Registrar, The University, Keele, Staffs (March 1)

Research Assistant (with a Ph D degree in enzymology or a good honours degree with research experience in enzymology) to Dr B T Cromwell, in the Department of Botany, to carry out research on enzyme systems involved in the biogenesis of alkaloids—The Registrar, The University, Hull (March 1)

Assistant Lecturer in Philosophy—The Secretary, Birkbeck College (University of London), Malet Street, London WC1 (March 4)

Assistant Lecturer (with special interests in either anatomy and/or microstructure or in aspects of the biology of algae) in the School of Plant Biology—The Registrar, University College of North Wales, Bangor, North Wales (March 4)

Assistant Lecturer in Civil Engineering—The Secretary of the University Court, The University, Glasgow (March 8)

Superintendent (graduate in physics, preferably with experience of administration in industry in the government service or in universities) of Laboratories in the Department of Physics—The Registrar, University College of Swansea, Singleton Park, Swansea, South Wales (March 8)

Reader/Senior Lecturer in Electronic Control or Electronics—The Registrar, The University, Canterbury, Kent, quoting Ref A7/68 (March 9)

CHAIR OF GENETICS—The Secretary of the University Court, The University, Glasgow (March 15)

LECTURERS or ASSISTANT LECTURERS (3) in the DEPARTMENT OF MATHEMATICS, The Royal University of Malta—The Inter-University Council, 33 Bedford Place, London, WC1 (March 15)

CHAIR OF MATHEMATICAL STATISTICS—The Registrar, The University, Hull (March 16)

UNIVERSITY RESEARCH FELLOW IN THEORETICAL PHYSICS (Atomic Scattering and Classical Mechanics)—The Secretary (NAT), University of Stirling, Stirling, Scotland (March 16)

ASSISTANT LECTURER IN PHYSICS—The Registrar, The University, Keele, Staffs (March 18)

CHAIR OF APPLIED MATHEMATICS and HEADSHIP OF THE DEPARTMENT—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (March 18)

LECTURERS (2) IN CHEMISTRY at Victoria University of Wellington, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (New Zealand and London, March 29)

RESEARCH FELLOW in the DEPARTMENT OF GEOGRAPHY, Research School of Pacific Studies, Australian National University, to work in cultural, economic or social geography in South-east Asia or the Pacific Islands—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, April 1)

ASSISTANT PROFESSOR (with a Ph D with emphasis on environmental physiology and energy metabolism, and teaching and research experience) of ANIMAL PHYSIOLOGY in the DEPARTMENT OF ANIMAL SCIENCE—Head of Department of Animal Science, University of Alberta, Edmonton, Alberta, Canada (April 15)

UNIVERSITY LECTURER (preferably with endocrinological interests) in HUMAN ANATOMY—Professor G W Harris, CBE, FRS, Department of Human Anatomy, University of Oxford, South Parks Road, Oxford (April 27)

LECTURER IN MICROBIOLOGICAL CHEMISTRY in the DEPARTMENT OF ORGANIC CHEMISTRY—The Registrar, The University, Newcastle upon Tyne

LECTURER in PHYSICS to be attached to the SOLID STATE GROUP (Electron Diffraction Section)—Professor M Blackman, FRS, Physics Department, Imperial College, London, SW7

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

Philosophical Transactions of the Royal Society of London Series A Mathematical and Physical Sciences No 1129 Vol 262 (14 December, 1967) Asymptotic Solution of Initial Boundary-Value Problems for Hyperbolic Systems By B Granoff and R M Lewis Pp 387–411 (London The Royal Society, 1967) 9*s* , $1 35 [1512

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue

The direct postal price per subscription for one or two copies of NATURE each week is

***12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire		**£14 0 0** each
United States of America	(by air freight)	**$48** each
Canada	(by air freight)	**$52** each
Elsewhere overseas by surface mail		**£14 0 0** each

(Charge for delivery by air mail on application)
*Shorter periods *pro rata* (Minimum three months)

MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered

12 MONTHS (52 issues and 4 indexes)

Number of Copies	*G B & Eire*	*U S A*	*Canada*	*Elsewhere (surface mail)*
		(by air freight)		
	Each	*Each*	*Each*	*Each*
3–5	**£13 10 0**	**$46 50**	**$50 50**	**£13 10.0**
6–11	**£12.15 0**	**$44 50**	**$48 30**	**£12 15 0**
12 or more	**£12 0.0**	**$42 50**	**$46 00**	**£12 0 0**

Multiple subscriptions must run concurrently Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address (ZIP essential for U S A)

Mr Crosland's Little Joke

Mr Anthony Crosland, president of the Board of Trade for half a year, is not merely an eminently reasonable man but resourceful as well, which is why there are few who can be entirely surprised that the project to build a third airport for London in the rolling green fields of Essex has finally come to grief. The story that he deliberately engineered this upset of his predecessor's scheme by sanctioning re-alignment of the runways at Stansted, which was bound to provoke the wrath of the Council of Tribunals, may be a gross misstatement, but it is one of those stories which is too good to be entirely untrue. In any case, to retreat from a well-prepared but irrational position as Mr Crosland has done is not only courageous but a welcome break with what seems to be the style of modern government. The residents of Stansted, and air travellers in the seventies, will understandably be delighted with the way things have turned out. The affair should encourage all those who believe that there is, or should be, some merit in pure reason.

The brief history of the Stansted project is worth repeating even though some of it has now become a part of British folk-lore. The hunt for a site for a third London airport began almost before the second airport, at Gatwick, came into service a decade ago. By 1963, a committee consisting largely of government officials came to the conclusion that Stansted was the best of all possible sites for the third airport, and towards the end of 1965 a public inquiry was begun to assess the weight of the objections to the proposal which had, by then, become apparent. The report of the inspector holding the inquiry was unambiguous—in his view, the siting of the third airport at Stansted was a "calamity" for the locality, and there should be an independent "review of the whole problem". In the event, the Government carried out an internal review which, for practical purposes, denied the validity of the inspector's objections. From there it was a simple step for the then president of the Board of Trade, Mr Douglas Jay, to insist that the project must go forward with despatch, and for the Government to dragoon first its supporters in the House of Commons and then the House of Commons as a whole into acquiescence. Throughout its struggle with good sense, the Government has been able to count on the shrill support of Mr Peter Masefield, the chairman of the British Airports Authority, who has turned out in the past year to be one of the most prolific writers of letters to the daily newspapers.

It is perhaps understandable that the way in which this decision has been stood on its head has made many of the Government's supporters in the House of Commons consider that they have been cheated or led up the garden path. Elsewhere, people will have been provided with a chilling illustration of how little can be done, with present arrangements, to divert a government from a chosen course, however foolish. But these are long-range matters, which is not to suggest that nothing more should be heard of them. It is, however, an immediate problem to know just how a sensible site should be chosen for the third London airport. How, one way or another, will it be possible to prevent the result of the inquiry now to be mounted seeming as if some official has stuck a pin at random into the map of south-east England? How is the machinery which has functioned so badly in the past few years now to be nudged towards a sensible choice?

One set of considerations ought by now to be so compelling that nobody can fail to grasp it. Briefly, in densely populated countries such as Britain, where the coastline is mercifully quite substantial, the obvious place for major airports is on the sea. Any other arrangement is bound to mean that increasingly noisy aircraft will increasingly distract ordinary people. It is true, of course, that it is sometimes necessary to destroy amenities—such as absence of unnatural noise—for the sake of some other social objective, and it may even occasionally be necessary to attempt some kind of balance between amenity and its cost. Yet there is no question that the noise which abounds in built-up areas near international airports is usually a kind of civic indecency. If there is any alternative to building near places which will eventually be occupied by people, and if the difference of cost in doing so is not more than, say, a third of the cost of building anyway, then the opportunity should be seized of avoiding unnecessary assaults on people's peace and quiet. But this case for building the next London airport near the sea is reinforced, for an airport due to come into service when supersonic aircraft may be flying, by the uncertainties which surround the social acceptability of supersonic bangs. Will supersonic transports ever be allowed to fly supersonically over land? And if they are, will not inland airports be a great nuisance to the airlines as well as to people living on the ground? With these uncertainties, who in his senses would now put money into inland airports when there are reasonable alternatives near the sea? It is curious, even now, that these uncomplicated considerations were given so little attention during the official arguments for and against Stansted as a site for the third airport, although the Government's most recent summary of the position a year ago did grudgingly acknowledge that

Stansted would have been a greater nuisance on the the grounds of noise than an airport at one of the several alternative sites on the Thames Estuary

There are, however, more serious charges to be made against the way in which the site at Stansted was selected. Looking back, it is clear that the case for Stansted was unreasonably influenced by the pre-existence of a single concrete runway at the site—a circumstance which could not have saved more than ten per cent of building on the site even on the basis of the Government's calculations Also included in these calculations was the comic guess that it would cost no more than £6 million of capital to improve existing transport links with the proposed airport to the point at which they could be considered good enough for the year 2000 (when the third London airport will presumably be still in service) But to argue like this is absurd In setting out to compare the costs of alternative sites, the Government should seek to do for airports what it insists the nationalized industries should do when making decisions about the new investments on capital equipment—some attempt should be made to lump together running costs and capital costs And the truth is, of course, that in circumstances in which the annual flow of passengers through the new airport is likely to be several tens of millions in the eighties, cheeseparing now about the initial cost is likely to be an exceedingly false economy The real need is for a much more realistic appraisal of the full costs of alternative sites from the point of view of the whole function of the airport and the whole complex of potential users It is particularly important to graft on to the study which is now to be undertaken—and Mr Crosland has promised that it will be a thoroughly comprehensive inquiry even though there are misgivings about the time that that will take—a proper study of the surface transport, freight as well as passengers The object should be to regard the new and non-existent airport as a part of a huge and integrated system and not as an isolated facility by itself It is, in other words, a splendid opportunity It will be interesting to see how well the Government rises to the occasion after making such a mess of its first attempt to choose a site

What Takers for Dr Dainton's Cure?

THREE years almost to the day after the appointment of the committee under Dr F S Dainton which has been looking into the causes for the drift away from science in British schools, the final report has been published On the whole, it is a perceptive and a liberal document Although the committee was charged with responsibility simply for the problem of the diminishing flow of young people into science and technology at the interface between British schools and the various establishments of higher education, it has creditably taken a wider view of its task In particular, it has quite accurately concluded that much of what it wishes to accomplish can only be done by reconstruction of the British educational system (To be accurate, the Dainton Committee has also acknowledged what seems to be the superiority of the Scottish system in comparison with what happens south of the border, and urges that the Scots should set their faces against supposed reforms of their system the effect of which would be to make the interaction between schools and universities in Scotland resemble more closely the relationship which now obtains in the rest of Britain) Fortunately, the need for change is now more widely appreciated than it has ever been, and it is not unreasonable to hope that a measure of change may actually come about In the circumstances, the Dainton Report is likely to find a more sympathetic reception than would have seemed likely even a year ago By the same test, unfortunately, its historical importance is likely to be less than if it had appeared sooner, when the going was still rough.

The swing away from science in British schools is, of course, a comparative affair The groups of young people following science studies in the sixth forms of British schools are still a growing proportion of the age group as a whole, but the groups following other kinds of studies are growing much more rapidly The result is that the balance between science studies and other studies in the senior classes of British schools is changing rapidly and to the detriment of the sciences One consequence is the difficulty there has been in recent years in recruiting people to fill the science departments at universities to their best advantage The Dainton Committee is right to take the view that this trend cannot be a healthy one at a time when there is a large unsatisfied demand for technical people in commerce and industry, and when science and technology as a whole are capable not merely of changing the character of life but of exciting the imagination as well Sensibly enough, however, the committee has set its face not merely against expedients that would artificially persuade young people to suppress their natural inclinations but also against attempts to develop artificial rules for saying how many people with which kinds of training British higher education should provide

So what, then, should be done ? Schools and universities have separate parts to play, but it is entirely proper that the Dainton Committee should put high on its list of remedies the view that British schools should provide a much broader curriculum for their pupils This, of course, is a crying need which even Scotland should not ignore The question which now needs to be answered is what kind of reform should now be undertaken It has been an open secret for several months that the Dainton Committee would urge that only in the most exceptional circumstances should pupils in British schools be allowed to abandon mathematics, which is entirely sensible But what form should the rest of the curriculum take ? The Dainton Committee has obviously been attracted by the talk in recent months of schemes in which students preparing for higher education would study three or four subjects as well as mathematics, and its own preference is for a mixture of science, social science and arts for everybody So far, so good The real problem is to know what should be done to bring about these changes

The committee would have done a useful service if it had been more outspoken on this issue Events in the last six months suggest that the time has come when several distinguished heads should be knocked forcibly together, and the Dainton Committee could have made a useful start For one thing, it is important that the Schools Council, which has responsibility for the British school curriculum, should be dissuaded from its introspective preoccupation, the pressure of external examinations (and the need somehow to diminish it) Its own proposals are narrowing, not broadening, and have served so far chiefly to undermine confidence in the council's capacity to function sensibly But it is also important that work should promptly be put in hand to design the kinds of curricula which the logic of the committee's proposals would imply, and on recent form there is very little to suggest that the Schools Council, which ought to be in charge, will be fit and able to do what is expected of it But there are also problems concerning teachers' organizations—who, for example, is going to persuade the science teachers whose enthusiasm has been chiefly responsible for experiments in science teaching in recent years that the time has now come to have less, not more, formal teaching in the schools ? One of the valuable discoveries which the Dainton Committee has to report is that students following science courses tend to be well looked after by well qualified teachers The question now is who should tell these talented people that they must spend less time behaving as if they were teaching in universities To be sure, it will be valuable to have Dr Dainton's support for the cause of more in-service training for teachers, more laboratory technicians in British schools and better means of persuading young people to take up science teaching The trouble, unfortunately, is that these needs have also been obvious for some time The most urgent need has become that of making them materialize It is, of course, a great absurdity that the British educational system has remained archaic for so long, but the prize will go to the one who can show how change can happen quickly

What the committee has to say about the universities follows naturally enough—universities must be more flexible about their requirements for entry By good fortune, it seems now very much as if the Standing Conference on University Entrance will be given advice in this direction in the months ahead The article by Professor L Rosenhead, a member of the Dainton Committee, on page 806, is one man's vision of how universities might quickly become better suited to the real needs of the schools But here, too, it is all too likely that the formal processes of consultation and the traditional unwillingness of those concerned with British education to consider seriously any but the most moderate of changes will blunt the present tendency towards reform

This, perhaps, is where the Government could help As it has turned out, and as it should be, the Dainton Report is not a piece of special pleading on behalf of science teachers but yet another comment on the inadequacies of British education It also stands out among public documents as a sensible statement of the part which should be played in education by science studies and of the reasons why some acquaintance with science should be considered important not merely for professional scientists but for everybody The trouble, of course, is that in the present balance between British schools and British universities, there is no room for this kind of appraisal On the whole, the schools are too preoccupied with specialist studies and the universities are forced as a result to be too preoccupied with the need for a broader education It is hard to see how this pattern can be changed except by the simultaneous agreement of the host of interested parties, but it is also plain that the need for change is urgent In the circumstances the Government could do worse than organize the kind of conference at which many interested parties could be persuaded to hammer out answers to the question which excessive modesty has persuaded Dr Dainton to leave alone

The Magic of Numbers

THE dead-pan send-up is a literary genre that seems now to be flourishing in the United States A few weeks ago there was the *Report from the Iron Mountain* Now there has appeared Professor D J de S Price's *Research on Research* (Journeys in Science, University of New Mexico Press, 1967) It is true that Professor Price appears to be entirely serious in what he has to say, but many of his readers will be bound to suspect that he has devised a witty demonstration of the inadequacies of what is called the science of science

That hindsight makes it seem as if scientific discovery points to a logical method of procedure has led some people to suppose that there must be an analogous logic in the way in which science is carried on —a logic the investigation of which merits a new and distinct discipline of social enquiry One approach of this "discipline" is to examine some numerical parameter assumed to be indicative of the forward march of science, such as the number of all papers published, and if possible to describe its variation in terms of some mathematical function From this kind of exercise, scientists of science expect, some useful insight may eventually emerge Among the principal difficulties of this argument is the assumption that the part of the individual in scientific discovery is either so predictable or so negligible that it can be altogether ignored. The crude macroscopic indices considered by the scientist of science can be used to demonstrate that, so inexorably does the juggernaut of science roll forward, not even a genius can make a significant contribution to its momentum. But it is not easy to know whether Professor Price is mocking when he says that "Science is, so to speak, a much more regular thing in its behaviour than are people". This assumption, a necessary point of departure for the science of science as usually construed, is an absurdity which lies at the other extreme from the Cleopatra's Nose school of history. Can it seriously be supposed that if Archimedes, Newton and Einstein had never existed, the present state of science would be no different?

Granted that the individual is insignificant, Professor Price shows how several intriguing "laws" may be set up. The "First Law of Research on Research" is that the "size" of science increases exponentially, whether judged by the number of scientists, scientific journals or scientific papers. It follows that "87½ per cent of all the scientists who have ever been are alive now". This is an impressive figure indeed and doubtless deserves its place in the *Guinness Book of Records*, along, perhaps, with a note that a similar figure would probably have been valid in 450 B.C. But what does it show? Professor Price offers this, that "science runs so much faster than people, so much more rapidly than civilization". This would seem to cast the man at the bench in the position of the Red Queen, which may be Professor Price's way of saying that the size of science bears no relation to such wholly immeasurable aspects as its quality or rate of progress at any given time. Alas that the latter aspects, which alone are of significant interest, fall outside the crude scope of the science of science.

No first law is complete without a second, and Professor Price announces the Second Law of Research on Research which states that the distribution of quality among scientific institutions, men or journals follows the approximately inverse square law typical of the Pareto law of distribution of income. "For men as for institutions", Professor Price explains, "the chance of doubling the size of achievement is uniformly about one in four, no matter what the size already achieved." From this follows the premise implicit in the foundation of the argument, that in science (though not, apparently, in art) the individual counts for nothing. "If Beethoven had not existed, other men would have written quite different symphonies, Beethoven's private property is unmistakable. If Planck, however, had not made his particular discovery, somebody else would have to have made it and rather quickly."

As the culmination of his essay, Professor Price produces statistics to show that the size of each country's research effort is proportional to its gross national product. Size is measured by the percentage of papers of each national origin indexed in *Physics Abstracts* and *Chemical Abstracts*. (He calls these "National Brownie Points", which is another reason for believing that he may not be entirely serious.) From this analysis it emerges that the Soviet Union, whose share of the world's GNP is 15·6 per cent, contributed 15·6 per cent of physics papers, while the equivalent figures for the United States are 32·8 and 31·6, respectively. This is a remarkable concurrence, but is it significant? Concurrences in historical and social phenomena have an unfortunate habit of being less meaningful than their counterparts in scientific experiments. George I, II, III and IV all died on a Saturday, but this does not by itself serve to establish the existence of a baneful influence between the Sabbath day and the House of Hanover. The science of science has far to go before it attains respectability. Only Professor Price can know whether his ingenious essay was written to help it on its way or as another obstacle in its path.

Mr. R. Brightman

THE death of Mr R. Brightman at his home in Cheshire last week-end is a particularly sad blow for *Nature*, for he played an important part in its production for the whole of forty years. He was a chemist by trade, and served for many years in the Dyestuffs Division of ICI Ltd. He had a passion for books and for the scientific literature, which is why no doubt he spent much of his professional energy on the management of the literature. But he also had a great affection for his work for *Nature*, which began with book reviewing and quickly graduated to other tasks. In the years since the Second World War, when many men of his age would have settled back in their retirement, he found himself writing a great proportion of the leading articles which appeared in *Nature*. More recently, he took on the job of working through *Hansard* each week in search of parliamentary news, and he was at the same time hard at work on a volume intended to celebrate the centenary of *Nature* next year. He would have wished no better monument.

Gloomy Post Office

THE prospects of the General Post Office for its final year before being established as a public corporation are described in a Government White Paper, just published (HMSO, 1*s*. 9*d*.), and presented to Parliament last week by the Postmaster-General. A Bill for the establishment of the corporation will appear later in the year. For the past five years a financial target of 8 per cent was set for the Post Office as a whole, but this has not been achieved. The overall return is expected to be nearer 7·6 per cent, the return from telecommunications, which reached the target, compensating for comparative failures of the postal services. Under the current reorganization these two sections will be managed separately and, because of the different nature of their activities, will aim for different targets. A net return target of 8·5 per cent for telecommunications (after historic depreciation but before interest and supplementary depreciation) has been set, but for the postal service, which is less highly capitalized, a margin of 2 per cent on total expenditure is being attempted. At present prices, it is unlikely that these targets will be reached. In fact, the postal service expects to make a loss, and, faced with capital expenditure for expansion and increased productivity over the next five years of £2,000 million, the Post Office says that charges must be brought into line with costs The position is being reviewed by the Prices and Incomes Board

The telecommunications section is aiming to increase the size of the system by 50 per cent without increasing overall manpower, by using more machinery Improvement of service for the existing 7 7 million subscribers will be the most important task in the coming year, and a net increase of half a million subscribers is expected The various local, trunk and overseas lines are all being increased, as are exchanges and the number of telex lines By March 1969 it is expected that 98 per cent of customers will be on automatic exchanges Automation is progressing in such fields as international telex and telegrams, data transmission services are being expanded, and additional submarine cable links with various European countries are being laid Aluminium conductors have been successfully used instead of copper in telephone cables, and further use of aluminium is expected to benefit the economy because of the high price of imported copper

The postal section will see two important developments in the coming year—the two-tier post system in the autumn with lowest rates of postage being open only to mail in "post office preferred" envelopes, and the inauguration of the National Giro Service at its Lancashire headquarters Modern techniques of management and marketing are being examined for staff and stamps, respectively, and post codes will be allocated to parts of London and twenty-five other towns and cities During the year, twenty mechanized sorting offices will be brought into service

New Units for Industry

THE process of changing all Britain's units from the old imperial system to the metric system is a messy business Colonel J S Vickers, chairman of the Planning Group of the British Standards Institution, which is planning the change, calls it "an agony" But at least everyone agrees that the medicine, once taken, will do the patient good The arguments are about who should take the medicine first In most countries which have made the change, the retail trade, which includes packaging, has adopted the new units first, but in Britain the opposite will happen The plans for the retail trade will depend on the recommendations of the Joint Committee on Metrication, a Ministry of Technology body whose chairman is Mr Arthur Wynne The committee is widely expected to accept a recommendation made to it by the CBI (see *Nature*, **216**, 1157, 1967) and propose the formation of a Metrication Board

Last week the BSI was able to announce its plans for the engineering industry After consultation with industry which seems to have been somewhat one-sided (of 1,600 firms to which the BSI sent its original questionnaire, only 250 replied), the BSI has prepared a draft programme which it is circulating to industry through trade associations The period of transition has been set at 1970–75 The terminal date was fixed by a Board of Trade decree, so all that really needed deciding was the starting date 1970 seems to have been the overwhelming favourite The first industry to go metric, chosen because its problems were likely to be the greatest, will be the engineering equipment manufacturers, who use the basic engineering materials to produce equipment which is then used by the process industries This time-scale will, the BSI says, fit in with the plans of the construction industry, which is on the way to metrication already Some 20,000 copies of the draft programme have been sent to engineering companies through their trade associations, and they have been invited to send comments to the BSI by March 29 Companies not members of any trade association can get copies from the BSI.

Another New Reactor

DESPITE its great cost, which might be expected to dictate caution, nuclear reactor design remains astonishingly diverse Almost every conceivable combination of coolant, moderator and fuel has been studied, on paper if not in actual hardware, although most of these systems are unlikely to evolve into commercial power reactors. Although Britain has so far tended to favour gas cooling for thermal reactors, the United Kingdom Atomic Energy Authority last week invited the Duke of Edinburgh down to Winfrith to open its latest reactor, which is water cooled In the event, the considerable skill of the authority at public relations had to be directed at those who thought the royal visit had cost a great deal too much, but the virtues of the reactor were not entirely forgotten It had, after all, cost £16 million itself

The reactor is called, somewhat inelegantly, the steam generating heavy water reactor, abbreviated to SGHWR It is a system in which moderation by heavy water is combined with cooling by ordinary water, which boils and drives the turbine generators in a direct cycle The design uses a number of pressure tubes, rather than a single pressure vessel, an arrangement with several important advantages The fuel, slightly enriched uranium dioxide, is contained in thin tubes made of zirconium alloy, 36 such tubes go to make up each fuel element Cooling water passes up the tubes, which are surrounded by an aluminium calandria (vessel) containing heavy water moderator

The electrical output of the station is 100 MW, which is fed into the National Grid The reactor can be refuelled either on-load or off-load, although the advantages of on-load refuelling seem much overrated. If the reactor is refuelled off-load, the whole job can be done in a weekend so that most customers are likely to choose this option The pressure tube design allows much of the fabrication work to be done in the workshop instead of on-site, which is a valuable advantage in places where welding technology is less advanced than it is in the United States The authority is tentative about quoting costs, but says that capital costs should work out at about £60 per kilowatt, with generating costs of 0 50 pence a kWh or less The reactor is a good plutonium producer, very much better than the advanced gas cooled reactor, and about the same as a boiling water reactor The design can also be adapted for natural, rather than enriched uranium The authority says that there would be no difficulty in building an SGHWR as big as 1,000 MW.

So far, however, the whole contracting position is a mystery The authority firmly says that "the team which built this reactor will take on contracts anywhere" Under these circumstances, the AEA would be the prime contractor and no move seems to have been made to license the consortia of industrial companies to build the design. The AEA has already submitted tenders in Finland, and has signed a contract for the supply of information to Japan; it seems determined to keep the SGHWR to itself. Meanwhile, the Minister of Technology is still wondering what to do with the nuclear power industry in Britain. He should think quickly, before the authority answers his questions for him.

Experimental Factories

from Angela Croome

A SECOND stage in the Akademgorodok (science city) experiment in Siberia is now actively under way. This involves the development of areas outside the main centre, containing experimental factories, design offices and special training facilities to speed the transition from good idea to industrial production. The scheme was put forward by the Siberian Academy of Sciences led by Academician Mikhail Lavrentiev in 1966 and adopted by the Soviet Government last year. The site chosen is about 2.5 miles from Akademgorodok on the banks of the Ob Sea and is to be called Pravye Chomy. The population will be limited to 15,000—much less than the total of 40,000 which Akademgorodok attained last year, its tenth anniversary.

The object is to improve the ways in which basic research is turned into industrial practice. The ideas, which will come from the research institutes of Akademgorodok, will pass to design offices at Pravye Chomy linked with the appropriate institute. Designs produced here will then be developed at centres on the spot which are described as "something between laboratories and factories". In these centres development will go at least as far as the production of prototypes, still under the guidance of the original inventor. Academician Lavrentiev commented, "We have recently come to the conclusion that the traditional 'conveyor belt'—academic institute/design office/industry—by which scientific discoveries are brought into practical use in industry, often works too slowly. The Siberian Design Office experiment, whereby valuable scientific ideas are brought to the point of practical industrial use under the direct control of the inventors themselves, has proved highly successful." The Institute of Hydrodynamics at Akademgorodok has pioneered the procedure. The hydraulic impact forging techniques introduced by the institute are estimated to hav esaved the Soviet oxygen equipment industry alone 100 million roubles a year. An interesting feature of the Pravye Chomy scheme is that most of the capital cost is being found by industry.

The scheme will be mostly operated by young people. This is seen as a unique opportunity to provide, after the 3–4 year development phase, not only effective designs but the people to put them to work on the shop floor. Linked to this is the introduction of a new type of degree to be given by Novosibirsk Technical College, shortly to be opened. This qualification will be intermediate between that of the full engineer and skilled factory hand. Novosibirsk University is adding an engineering faculty soon in support of the new technological developments. A large workshop block with a floor area of 1,500 square metres is nearly ready at Pravye Chomy.

French Scientists on Strike

from our Paris Correspondent

IF French politicians of all political parties rarely show an active and informed interest in research—election speeches contain polite but woolly references to the "progress of science" but are singularly lacking in precise policies, and the discussion over finance each year is carried on before a virtually empty House—scientists themselves seem to have long ago made up their minds to direct the attention of politicians and the Government to their future.

This is why an order to strike was given by two trade unions two weeks ago at the Centre for Nuclear Research at Saclay. The immediate aim was to protest against a plan for professional classification which would harm certain categories of personnel. In the longer term the question was that of fixing a date for a possible reorganization of the Atomic Energy Commission (the CEA). Is the CEA, which provides work for approximately 30,000 people and which, because of the size of its budget, is in French science a considerable *force de frappe*, threatened with disruption? In political as in research circles, many people would very much like to reduce this tremendous power by giving to various other organizations functions which originally were mistakenly attributed to the CEA for reasons which are no longer valid. The CEA, even under this system, would remain, if only for military reasons, an institution of considerable importance. Inevitably, however, a certain amount of reorganization would take place. At all events, it is doubtful whether strike action would weigh very heavily on Government decisions which will probably be taken at the highest level and in accordance with well known political and military strategy.

Despite this, another strike took place on February 20 and 21, organized this time on a national scale by the three research workers' unions. It seems that the strike was 70–80 per cent effective. It is the mode of operation of the National Centre for Scientific Research or CNRS (6,000 research workers, 8,500 technicians) which is the issue at stake, or, rather, the method of professional promotion agreed on by the responsible ministry, the Education Ministry. Having decided to push the research workers into the industrial sector, by force if necessary, the minister, M. Alain Peyrefitte, has created a bottle-neck between the first grade of the CNRS hierarchy, that of research assistant, and the second grade, that of research organizer. This year, seventy-nine assistants, all holders of doctorates and having the recommendation of the commissions concerned, have not been able to enjoy the promotion they were expecting, which is virtually forcing them to leave the CNRS once and for all.

Those who defend this measure argue that the almost automatic passing from one grade to another leads to "functionalization" of research and threatens to make the CNRS, which ought to be a dynamic body, stagnate. Their opponents, while agreeing that this argument does have some justification, deplore the improvised nature of this new policy and see in it a threat to basic research. The desire which the minister professes for "irrigating" industry is for them based on a dangerous illusion. French business men who are extremely timid in their attitude towards research are certainly disinclined to pour capital investment into this field and thereby offer scientists attractive posts. Furthermore, most firms are wary of research workers with a university background and prefer, when recruiting scientists, to look for them in the major colleges such as the Polytechnique or the Centrale. And university lecturing, also suggested as an alternative solution for those excluded from the CNRS, has been completely transformed in recent years, with the result that a teaching background is insisted on for lecturers. It is not at all certain that the universities will find satisfactory recruits among the members of the CNRS who had chosen precisely this field in order to pursue their work without any teaching commitments. The only course for those affected by this measure—which from now on must be repeated year after year—seems therefore to be to yield sooner or later to the temptations of the brain drain. The American "head-hunters" indeed have been making conquests in France for some time, and young people in France are beginning to have a better knowledge of English than their elders.

Money and Health

THAT the "healthiest" countries (judged in terms of mortality) spend most on health services is one of the conclusions reached in the 1967 World Health Organization report, *An International Study of Health Expenditure* (price 12*s*.) covering 29 countries. The objectives of this report were two-fold: to compile comparable information on expenditure on health services and on methods of financing such services, and to develop a standardized framework for national health accounting that could be used as a routine aid to health planning in all countries.

Most of the figures in the report were drawn from questionnaires, and the countries covered were not, it is emphasized, necessarily representative of all countries in the world because of the difficulty of obtaining information from countries with lower standards of living. Estimates of health expenditure for each country are compared with gross national product and national income.

It seems that over the period of study Israel, Canada, and the United States spent the greatest proportion of national income on health services, while the proportion of Gross National Product devoted to health services varied from 2.5 per cent to 6.3 per cent in countries providing full information. Countries with relatively high standards of living tended to spend more on health expenditure than countries with a lower standard of living. As the latter countries have on the whole poorer health than richer countries, less was spent both absolutely and in relation to total resources where the need was greatest.

The report states that generally there is no evidence of correlation between health expenditure and the need for health services; rather, health expenditure is presumably influenced to a large extent by the "felt needs" of governments. No country was found in which less than 25 per cent of the money spent on health services came from public funds and among the high-income countries those receiving heaviest government support were not those allocating most money to health expenditure.

Breaking down the capital expenditure on health services, with the exception of Pakistan and France, 18 countries allocated 88 per cent or more to personal health services. Furthermore, hospitals took more than 74 per cent of capital expenditure in all countries except Chile, Czechoslovakia and Yugoslavia. The United Kingdom was well down the list with only 76.4 per cent provided through hospitals compared with 99.7 per cent in Canada, although a spokesman at the Ministry of Health said that 14 hospitals had in fact been built in England and Wales since 1948.

APPROXIMATE TOTAL EXPENDITURE ON HEALTH SERVICES (CAPITAL AND CURRENT) AS PERCENTAGES OF GROSS NATIONAL PRODUCT

	Year	Total health expenditure (£ millions)	As % of GNP
Israel	1961–62	40.71	6.3
United States	1961–62	1,303	5.8
Australia	1960–61	262	5.2
Poland	1960	311	3.7
United Kingdom	1961–62	1,016	4.2

Looking to the future, until cost-benefit analysis and other techniques become applicable to the selection of targets for health programmes, the report suggests that it is desirable that the costs of health services should be consistent with a chosen long-term plan, and that the plan should be firmly based on economic realities.

Developing Oxford

from our Oxford Correspondent

As *Nature* went to press, Congregation at Oxford was voting on a proposal for acquiring new sites in north and central Oxford, principally for the university's scientific and administrative institutions. The administration of the university has been conducted from various buildings in different parts of Oxford, the Registry being, for example, in the Clarendon Building in the centre, while the financial department is three-quarters of a mile away in Wellington Square. In 1965, it was proposed that the Registry should expand into the premises of the nearby Indian Institute, which would then be displaced if not dismembered. Much criticism was directed at this proposal and Bodley's librarian resigned on account of it. Now, because the university has bought a number of houses around Wellington Square and also because the Franks Commission recommended that the administrative buildings should be in one place, the Hebdomadal Council has decided to apply for planning permission to redevelop Wellington Square, and move all the administrative buildings into that area. But a new Indian Institute library is already being built on top of the new Bodleian. If, then, the new proposal is accepted, all but the ground floor of the Clarendon Building and the old Indian Institute will be empty.

The council has not yet put forward suggestions for using this extremely valuable area in the centre of Oxford, considering it "premature" until planning permission has been granted for the Wellington Square development. It is possible that Hertford College will take over some of the Indian Institute building, but part at least will continue to be used as a library. Similarly, it is suggested that the Taylorian Institute and Modern Languages Faculty will take up residence in one corner of Wellington Square, leaving another large central area empty. Here again no decision has yet been made on how to use the space.

In north central Oxford, where most of the present science faculty buildings stand, the university has done well to buy (or to be in the process of buying) one million square feet of buildings, after the recommendation of the Holford Committee which reported in 1963 New departments of psychology and zoology are at present being built and the Radcliffe Science Library, the School of Geography and the Physics Laboratories are being extended Since the Holford Committee sat, sixteen houses have been bought from colleges for the use of the Social Science Departments, and some of these have already moved into their new accommodation Congregation will now have voted on the proposal to buy another nineteen houses, with 100,000 square feet, for science facilities Despite the Government's statement of January 16, 1968, further projects may be included in the building programmes for 1970 A new computer library will be built, and the adjacent Departments of Engineering, Survey and Geodesy and Metallurgy will be extended The professors of these departments have already agreed to share as many facilities as possible, following the example of the zoology/psychology building, which will, the Hebdomadal Council states, guide many future developments

Reinforced Plastics

THE production of carbon fibre reinforced plastics (CFRP) is now going ahead even though licensing and financing arrangements between the National Research Development Corporation and the three firms involved—Courtaulds, Morganite and Rolls-Royce—have not yet been finally decided Rolls-Royce is producing the plastics for its own use, but Courtaulds and Morganite will sell CFRP in the general market Morganite is quoting prices of £35 per lb for batch fibre and £100 per lb for continuous fibre, but it is acknowledged that prices will fall considerably when mass production is achieved.

The development and applications of these very strong plastics were described by Mr L N Phillips, head of the Plastics Technology Section, Materials Department, of the Royal Aircraft Establishment, Farnborough, at a joint session of the plastics and polymer group of the Society of Chemical Industry and the London Section of the Plastics Institute, on February 22 Mr Phillips began by pointing to the considerable experience of RAE in the development of cellulose, asbestos and glass reinforced plastics for structural purposes. The general engineering opinion was that glass fibre has too low a Young's modulus, compared with metals, to be attractive for structural purposes Conversely, it was reasoned that a new fibre with a Young's modulus three to six times greater than glass would be of considerable interest

Attention was focused on carbon fibres some four years ago, because of the wide difference between the properties of commercial fibres then obtainable by rayon pyrolysis (Young's modulus 6–9 million lb per square inch, with ultimate tensile values of 50,000 lb per square inch), and the properties of graphite whiskers (Young's modulus between 100 to 147 million lb per square inch) Details of the RAE processes for making high-strength high-modulus carbon fibres could not be given for commercial reasons, but the principle is to preserve the orientation already existing in a highly aligned textile fibre as the polymer is destroyed by heat (The inventors are W Watt, W Johnson and L N Phillips) Experiments with the composites at RAE have shown that water absorption is not a difficulty and that the fatigue life under various conditions is excellent, the heat build-up during fatigue testing being much less than with glass and other non-conducting fibres Friction and wear tests carried out at Farnborough have shown that when carbon fibres are incorporated into thermoplastics and thermosetting resins, the coefficient of friction is lowered and the rate of wear enormously reduced It seems as if a new class of bearing materials has been created But many other uses for the materials have been uncovered—the Rolls-Royce Company has, for example, used them for very large fan blades in aircraft engines, which have a clear advantage in efficiency over titanium Aircraft structures, chemical plant, marine uses and space applications were also mentioned

Considerable increases in the stiffness of thermoplastics are obtained by incorporating small amounts of chopped carbon fibres—for example, 10 per cent weight addition can increase the modulus by 100 per cent This is important in the manufacture of large mouldings

Sensible suggestions for further uses of CFRP are welcomed by the Ministry of Technology

Crack Detector

THE development of a new instrument for detecting invisible cracks in iron and steel surfaces was announced on Monday by the National Research Development Corporation The new instrument works on the principle that a coil carrying an alternating current will induce eddy currents in nearby conducting materials When the coil is moved over a surface crack, the crack causes variations in the eddy currents leading to a change in the voltage across the coil This can be detected by a meter or made to sound a warning buzz in an earphone worn by the operator

Eddy current techniques in non-destructive testing are not new, but up to now they have not been widely applied to ferrous materials This has been because variations in the distance of the coil from the material under examination, such as might be caused by paint or rust layers, lead to interfering effects The advantage of the new instrument is that it can be compensated for variations in the gap between the coil and the metal This means that once the electronic circuit has been balanced for a particular specimen the instrument can be used over rough surfaces which may be covered by paint or rust, and over welds

The initial impetus for the design of a crack detector was provided by the discovery of cracks in the hull of the nuclear submarine HMS Dreadnought The instrument was developed by the Admiralty Materials Laboratory at Poole, and the patent rights were assigned to the National Research Development Corporation for exploitation Two licensees have been appointed to manufacture and sell the instrument

Because the new detector is simple, portable and rugged, it is likely to find many applications for testing structures in the field Time savings of more than 80 per cent are expected when compared with conventional magnetic methods of crack detection, which involve cleaning the surface under examination About

70 prototype crack detectors made by the Admiralty Materials Laboratory are at present in use in dockyards and research establishments The new instrument is proving of interest to British Rail, which has recently been seriously troubled by cracks in railway lines A special version is in the process of development for fitting to railway wagons so that the track can be inspected at high speed

Scientific Memorabilia

A PLEA for the preservation of unpublished scientific records, manuscripts and correspondence has been made by the President of the Royal Society and the Master of the Rolls The Royal Society and the Historical Manuscripts Commission have now formed a standing joint committee under the chairmanship of Sir Harold Hartley with the aim of locating, preserving and making accessible this material The committee is to prepare and publish a guide to the location and content of the personal papers of leading British scientists and technologists from the sixteenth century until, and including, the time of Lord Rutherford (but excluding scientists still living) The preparation of this guide has been made possible by a grant from the Goldsmiths' Company The librarian of the Royal Astronomical Society, Dr R E W Maddison, is to be editor Many of the papers are still in private possession, and Professor Blackett and Lord Denning are appealing to all owners of such papers to write to Dr Maddison (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W1) and to inform him of what they possess The papers will remain the owner's property—the aim is to locate the papers, to ensure their preservation, and to make them available in original or copy to historians

New Ways of Making War

A TWO-DAY conference on chemical and biological warfare last week in London served at least as an opportunity for breaking down what Lord Ritchie-Calder, chairman of the conference, described as the conspiracy of silence on the subject The conference was held under the auspices of the newly formed J D Bernal Peace Library, and was attended by scientists and science journalists from several countries Lord Ritchie-Calder set the tone for the proceedings with a reminder—culled from the late Professor Joliot-Curie—of how weapons like these might be used without the intended victims knowing

A long list of known chemical weapons was provided by Mr J Perry Robinson At one end of the spectrum are the so-called riot-control agents—lacrimators and the rest—which seem to be lethal in sufficiently high concentrations Nettle gases, dichlorformoxime, for example, sting hard Blood gases such as hydrogen cyanide block oxygen circulation Vesicants, of which mustard gas is typical, injure all kinds of tissues and can therefore be lethal Involatility enhances their effectiveness Then there are nerve gases which inhibit cholinesterase and which are therefore the most rapidly lethal of these agents Mr Robinson was also able to describe several means by which these agents can be disseminated—one of the essential tricks of the trade Defence, he said, would probably be too expensive for most countries

Academician I Malek from Prague had very little new to say, although he emphasized the self-spreading capacity of biological agents and their cheapness He argued that the only defence against biological weapons was an international agreement to forbid their use

The uses of defoliants were also discussed at the meeting, largely because of their use in Vietnam by United States forces According to Professor Arthur Galston, professor of plant physiology at Yale University, 1,000 square miles of Vietnam were dealt with in this way in the first 9 months of 1966 Dr F Kahn of the University of Paris held that agents like these can be toxic to human beings—notwithstanding official statements to the contrary Dr Kahn is a member of a scientific commission set up for the International War Crimes Tribunal which met last year in Stockholm His evidence for the lethality of defoliants is based on evidence collected orally by a government committee in North Vietnam and experiments carried out with ducks

Dr J H Humphrey, deputy director of the National Institute for Medical Research of the United Kingdom Medical Research Council, had a practical suggestion to make He argued that there would be great benefit in an arrangement by means of which the research establishments engaged on chemical and biological warfare were to become non-secret places, at least for a trial period Then, at least, taxpayers would know what was being done with their money

Listing Overseas Visitors

DIFFICULT as it is, tracing the names and numbers of overseas academic visitors at present undertaking research in Britain is not impossible Two almost up-to-date lists have been compiled for United States and Commonwealth visitors showing where they are and just what they are doing

The US directory of American university teachers and senior scholars for 1967–68 was prepared by the US Information Service of the American Embassy in London and contains over six hundred names The present location, field of study, the awards covering the research, and the university or institute which the visitors attended in the US are all quoted Data are based on information provided by registrars and other officers in British universities and, at this stage, copies are available only to university registrars (The US Embassy says that it is unable to supply further copies on demand)

The second list, prepared by the Association of Commonwealth Universities, is based on information furnished by the registrars of member universities and university colleges in overseas parts of the Commonwealth, and of former member universities in the Republic of South Africa Some 630 visitors are currently in Britain and there is a list of about 360 visitors shortly to arrive, dates of departure are given where known By circulating copies of the list to universities, learned societies and other interested bodies in Britain, the association hopes that this will assist contact between the members of these bodies and current or prospective visitors

Although the lists are incomplete, they provide a useful service which could usefully be taken up by countries outside the US and the Commonwealth which also have senior scholars in Britain

Preventing London Flood

THE possibility of catastrophic flooding in London has often been discussed, particularly since the disastrous floods in Florence. The idea of a barrier across the Thames to stop such a flood has been suggested on several occasions, but all schemes appear to have met with opposition, sometimes short-sighted, it seems. Professor Hermann Bondi, chairman of ESRO, who is very concerned about the possibility of flood, has just published a report called the *London Flood Barrier*. It seems that Professor Bondi was approached by the Ministry of Housing and Local Government in October 1966 to consider the whole question of a barrier, not only its desirability and practicality, but also its possible design. Professor Bondi admits that he is "not a civil engineer"—some may criticize the report on this ground alone—but a flood barrier may well be the type of problem which needs an outsider's view, cutting as it does across several interests. In any case, the report deserves serious consideration.

Professor Bondi could scarcely make the frightening consequences of a serious flood in central London more clear. As he says, "the case for preventing the flooding of a major part of London during a surge tide seems to me enormously strong. We are at risk all the time and further delay only invites the disaster". Statements like this, even if slightly exaggerated, should not be taken lightly. Rumblings like this were heard before the Aberfan disaster.

The advantages and disadvantages of a permanent rather than a movable barrier are also discussed by Professor Bondi. A permanent barrage or dam, with locks in the Woolwich region, although expensive, would be the best solution if seen in the context of a major plan for the development of the south-east. A barrier of this type would be an effective flood defence as well as adding to the amenities of the Thames. Regretfully, Professor Bondi concludes that this scheme would not answer the immediate problem. He therefore moves on to discuss a removable barrier, one which would only be put in place when there was imminent danger of a surge tide flooding central London. Such a barrier would have no use other than flood prevention.

He rejects the idea of a retractable barrier close to the mouth of the river. It should be possible to find a site further upstream where a narrower opening in the barrier would not seriously impede shipping. Three possible locations are suggested: just below the Ford Motor Works, just above Dagenham Dock, and in Woolwich Reach. In the case of the first two locations, a clear opening of 800 ft., or perhaps 750 ft., might be acceptable to shipping interests. In the case of Woolwich something in the range of 350–500 ft. might be considered if the river banks were cleared of mooring berths. These sites are compared with the barrier at Long Reach considered in previous reports of the consulting engineers which required minimum clear openings of 1,400 ft.

The Government appears not to be apathetic to proposals for a flood barrier. In a written answer to the House of Commons on February 20, Mr Anthony Greenwood, Minister of Housing and Local Government, mentioned that the Greater London Council has undertaken to investigate, in consultation with the Port of London Authority and navigation interests, the relative merits of the two types of barrier, fixed and movable, and the most suitable site for one. Presumably the Bondi report will be taken into account in these discussions. The minister is also going to consult the South East Economic Planning Council on the wider implications of the projects.

Parliament in Britain

Technological Community

THE Prime Minister, Mr Harold Wilson, was pressed last week to give more details of his proposals for a European Technological Community. Mr Norman St John Stevas suggested that it had been one of the Prime Minister's happier initiatives—the only one, another member interjected—and that it should be pursued with much more vigour. Dr David Owen said that it was foolishness to refuse to share the technology of Capenhurst nuclear fuel enrichment plant with other European countries. By doing this, the British Government was driving them to establish their own plants. Mr Heath thought that the Technological Institute was a better idea than the technological community, but that enrichment would be covered by the terms of the non-proliferation treaty. The Prime Minister was not very enlightening. He said that discussions about the community had been held with representatives of the Dutch Government; the West German Government had welcomed the idea. As for fuel enrichment, the British Government had said that it was prepared to join with Europe in the setting up of a system for the production of enriched uranium-235. Britain had more know-how than others, he said, but they had cheap electricity. (Oral answer, February 20.)

Research and Development

DR JEREMY BRAY, Joint Parliamentary Secretary at the Ministry of Technology, told Mr Gwynfor Evans, the only Welsh Nationalist member in the House, that research and development expenditure in England supported by his department in the year ending March 31, 1967, had cost £219.5 million. Alas for Mr Evans, Dr Bray revealed that only an additional £2 million had been spent in Wales in the same period. (Written answer, February 20.)

Channel Tunnel

MR JOHN MORRIS, answering questions for the Ministry of Transport, showed no inclination to cancel the Channel Tunnel project. Mr Clark Hutchinson said that the whole project was out of date, and asked when the Government would stop wasting public money and time on these futile projects. Mr Eric Lubbock asked for a pause in the plans to see how well the new hovercraft service using the SRN 4 went. Mr Morris said that the expected growth of traffic over the next thirty years showed that the tunnel was economically preferable to the alternatives. (Oral answer, February 21.)

Computers

MR WEDGWOOD BENN, Minister of Technology, said the number of computer installations in operation or on order in the UK in 1970 would be not less than 5,000. Not less than 1,500 installations would by then be at the planning stage. These revised estimates would mean that more computer personnel would be needed. By 1970, there would need to be 300 advanced programmers, 20,000 people falling into the category of systems designers or systems analysts, and 25,000 operators. (Written answer, February 22.)

NEWS AND VIEWS

Boom in Radio Astronomy

It seems already as if 1968 will be a vintage year for radio astronomy Last week, from Cambridge, there was described in *Nature* the discovery of radio signals from a pulsating radio source which seem as if they may turn out to be signals from one of the long-sought neutron stars Now, this week (see page 818), there comes evidence of a survey of the sky for radio sources at a frequency of 2,700 MHz which seems as if it may reopen some cosmological discussions which had seemed quite recently to have been finished

The signals which may come from neutron stars were recorded by the Mullard Radio Astronomy Observatory at Cambridge using a new radio telescope which can detect sources considerably fainter than previous surveys They are unusual because they consist of an emission of descending frequency which repeats itself every 1 337 seconds This repetition period is maintained with breathtaking accuracy—the true period is constant to better than one part in ten million Up to now, four of these peculiar sources have been discovered, although the position of only one of them was given in the article in *Nature* last week by Dr A Hewish and his colleagues (*Nature*, **217**, 709, 1968)

Neutron stars are believed to represent the final stages in the life of certain kinds of stars When the nuclear fuel sustaining these stars is exhausted, they contract to become what is an extremely dense star known as a white dwarf, the size of which is comparable with the Earth White dwarfs are difficult to detect because they are rather faint objects, but about 250 of them are known to exist The next stage in the evolution of these stars may be the gravitational compression of white dwarfs to neutron stars

Much of the observational interest of the new discovery stems from the way in which it is possible to use the character of the signals which are received at the Earth as a means of fixing an upper limit for the distance of these objects Briefly, ionized hydrogen in interstellar space should modify by dispersion the character of the radio pulses reaching the Earth, and this line of argument suggests an upper limit of 65 parsecs for the object which has so far been studied in detail, which in turn suggests that these pulsating radio sources may be comparatively common in the galaxy Obviously there is a staggering wealth of observation now to be undertaken

The new survey of the southern hemisphere is a different story For several years, radio astronomers have tried to distinguish between different models of the universe by making counts of radio sources One simple procedure has been to plot log N against log S, where N is the number of radio sources having a radio flux greater than S The result is sometimes a straight line, and the slope of this line has some importance for cosmologists On the simplest view of a Euclidean universe containing a uniform distribution of similar sources, the slope of the "log N–log S" curve should be -1 5 Apparently this is also the value to be expected if the steady state view of the universe holds

Up to now, counts of radio sources outside the galaxy have led to values of -1 8 for the slope of the log N–log S curve On page 818 of this issue of *Nature*, however, is a paper by an Australian group who have used the 210 feet Parkes radio telescope to obtain a slope of $-1{\cdot}4$ The chief difference between this and previous surveys is the choice of observing frequency, the new result refers to radio fluxes at 2,700 MHz whereas previous source counts were compiled at much lower frequencies

This suggested to the Australian group that the discrepancy between their result and the previous work may be explained by a detailed examination of the spectra of the sources used in the different surveys Bearing out this notion, there seems to be a large range in the form of radio source spectra As well as the problems posed by possible differences in the spectral content of the various surveys, the type of radio source observed seems to depend to some extent on the frequency at which the counts are compiled For instance, the new survey contains many quasi-stellar objects which were not in an earlier count made at Cambridge The outcome of all this uncertainty is that the value of the log N–log S curve as a means of distinguishing between theories of the universe is made even more questionable

Plants for South Kensington

The department of botany of the British Museum (Natural History) has received as a bequest the herbarium of the late Georges Le Testu of Caen The collection consists of about 15,000 specimens of flowering plants and ferns from Africa, and will be very useful to botanists working on the classification and identification of plants from this part of the world

Le Testu was trained as an agronomist and worked for an agricultural firm in Dahomey during 1900–1902, and for another in Mozambique from 1904 to 1906 After that he entered the French colonial service and served in Gabon and Oubangi-Chari from 1907 to 1934 Throughout his time in Africa, Le Testu collected plants as often as his duties allowed Of his collection, he gave one set of plants to the Muséum National d'Histoire Naturelle in Paris Many of these were type specimens, from which the original descriptions of species were made This Paris collection was used by F Pellegrin for a series of papers entitled "Plantae Letestuana Novae" published in 1923–1955 Le Testu's Paris collection was also the chief source for the *Flore du Mayombe*, and for various other works about the plants of this part of Africa

The plants received by the British Museum constituted the other part of Le Testu's collection, and are important because they include many isotypes, that is duplicates of the type specimens held in Paris The bequest is very valuable because many of these plants have not been available at the British Museum before The Le Testu bequest fills a gap that has been a cause of difficulty to botanists working in London on floras of, for example, tropical East Africa—a project which is being carried out jointly at the Museum and at the Royal Botanic Gardens, Kew

The British Museum's herbarium, consisting of preserved flowering plants, bryophytes, lichens, fungi and algae, is available to anyone engaged in work for which they require to study this plant material The value of the collection is mostly to those who are preparing floras—identification manuals—of the plants of a particular region, and monographs about particular groups of plants This sometimes requires considerable rethinking of classification, and it is preferable to have preserved specimens to refer to than to have recourse only to written accounts The collection at the British Museum is about two-thirds of the size of that at Kew, and one and a half times as large as the third national collection which is in Edinburgh

Marine Sediment Studies

THE meeting last Thursday of the Marine Studies Group of the Geological Society of London was devoted entirely to recent work on Holocene marine sediments near the British Isles Six papers at the meeting, organized by Mr A H Stride, dealt with sediment deposition in environments ranging from an estuary to the sea floor of the English Channel It was made clear how factors such as current strength, exposure and source of sediment material have affected sediment deposition in the past and still do Unfortunately, only half an hour was allowed for each paper, which was a pity, particularly for a paper on estuarine sediments read by Dr J E Prentice Dr Prentice is in charge of a research team from King's College and Sir John Cass College which has been working on sediments of the Thames Estuary for the past 6 to 7 years

Various aspects of the work of the team have been published before, but this meeting was the first time that the work as a whole has been summarized The importance of the research on the Thames cannot be underestimated, for it is inextricably bound up with long-term economic planning of the future of the Thames Only last week, a new scheme was proposed for a barrier across the river by Professor Hermann Bondi (see p 800) A further scheme in a wider context which would involve not only the river and the docks, but roads, motorways and airports as well, was also outlined by Mr John F F Clarke in last week's *New Scientist* (Vol 37, February 22, page 402)

The sediments of the Thames Estuary extend over an area of more than 500 square miles, are up to 100 feet thick and are made up of a variety of materials from finely laminated clays to coarse conglomerates What the sedimentological team found surprising was that all the sediments are mobile, and they would only stop moving if there were a substantial fall in the sea level Although there is no evidence of an overall increase in silting up of the estuary during the period of research, there had been many changes in the distribution of sediments in the outer regions A system of channels, the Edinburgh Channels, for example, which was navigable ten years ago is rapidly silting up—other systems of deep channels, however, seem to form to take its place

For the purpose of the research, the Thames was divided into three parts the inner estuary (as far down as Southend), the middle estuary and the seaward outer estuary In the inner estuary, mud deposition is dominant Fine clay in suspension enters from upstream and, on meeting the sea-water, flocculates and begins to fall through the water column This takes up silt and fine sand, and forms a dense suspension of black "fluid mud" which clings to the bed of the river It is normally kept in motion by water movement, but the fluid mud layer can also flow by gravity into channels and hollows Erosion of mud banks is apparently reduced to some extent because the Thames embankment is kept in a reasonable state of repair Shipping, however, has an effect because the washes help in the erosion of mud flats and in keeping the fluid mud in suspension In the middle estuary, the characteristic sediment is fine sand, although there are also fine clay and coarse pebbles The possible sources of these sediments were described by Dr Prentice

Mr N H Kenyon spoke on the phenomenon of sand ribbons—long ribbons of sediment, known to be up to 4 miles long and up to 200 yards wide, found on the sea floor around the British Isles in most of the areas where the tidal currents have maximum speeds near the surface of the sea of about two knots or more They can be used to infer present-day transport paths of the bed load, but, because they are not usually preserved, they are of little use as indicators of palaeocurrents The ribbon pattern may, however, be preserved in negative as linear shell beds, because living organisms have been seen to prefer the more permanent coarse material between the ribbons It was suggested that the material of the ribbons is a shelly sand that is in a continuous but restricted supply It is derived mainly from the reworking of relict sediment and from the shelly material of the local benthos

Looking Backwards for Resonances

from a High Energy Physics Correspondent

ONE of the most exciting aspects of high energy physics in recent years has been the discovery of very large numbers of largely unsuspected resonances and the determination of their properties A report of a recent experiment performed at the zero-gradient synchrotron at Argonne National Laboratory (A D Krisch *et al*, *Physical Review*, **164**, 1661, 1967) demonstrates clearly for the first time the value of a powerful yet simple new technique for studying such resonances in the pion–nucleon system

Because these resonances have such short lifetimes that they cannot be "seen" in any direct sense, the traditional methods of determining their masses, widths (lifetimes) and internal quantum numbers have been to look for anomalous variations of total cross-sections for scattering processes, and the enhanced groupings of two (or more) particles in inelastic experiments. Then the spins and parities of these states have been deduced from angular distributions of the outgoing particles in the elastic scattering events. The new idea is to study pions (in this case negatively charged ones) scattered at 180° from proton targets. When this backwards elastic differential cross-section is plotted against incident beam energy it exhibits a most striking structure, which can then be interpreted almost trivially in terms of resonance effects.

In the present experiment, where the incident energy range is from 1·6 to 5·3 GeV/c, there is evidence for some nine peaks and dips (many of which stand out quite vividly) superimposed on a smooth and steadily decreasing background. The interpretation of the background effect is for the present purposes unimportant, although models for it in terms of elementary or alternatively Regge baryon exchange have accounted for it in a reasonable manner, all that one requires is that it be smooth and should not change sign. Then each pronounced peak or dip is interpreted as the effect of the pion and proton forming a resonant state during the scattering so as to produce constructive or destructive interference with the background term. As the incident energy at which a peak or dip occurs is trivially related to the mass of the resonances, these masses are effectively measured directly. Perhaps the most elegant feature, however, is that resonances of positive parity interfere constructively to produce peaks, and negative parity resonances produce dips, so that the parity of a resonance can be read off from the curve at a glance. The determination of such other parameters as elasticity or partial width is on much less firm foundation, but at least some indication of their values—to within factors of two, say—may be obtained by detailed analysis.

The present experiment has not only shown the value of the technique but has also provided the theoreticians with at least two big problems. First, there is a dramatic destructive interference (which the reader is urged to view for himself) at around 2·2 GeV resonance mass, in which the cross-section drops by two orders of magnitude. Second, there is a large narrow peak at a resonance mass of about 3·25 GeV, suggesting a resonance there which has a width of the order of 1 per cent of its mass. That such a stable particle (half-life about 10^{-22} seconds) should exist at so high a mass will not be easy to explain.

Italian Crystallographers

from a Correspondent

THE newly founded Italian Crystallographic Association held its first general assembly in Perugia from January 11–13, 1968, in the Department of Chemistry of the University of Perugia, under the presidency of Professor F. Mazzi. The general assembly was combined with a symposium on the subject of four circle diffractometers. The two introductory lectures were given by B. T. M. Willis, who gave a general account of the whole subject.

Papers which followed covered the selection and operation of diffractometers. W. A. Wooster (Cambridge) maintained that the accuracy of 0·01° usually quoted by makers of four circle diffractometers is not necessary, except on ω- and 2θ-circles, when they are used for accurate measurement of lattice dimensions. He also discussed the relative merits of absolute-reading and difference-reading digitizers. J. Hornstra (Holland) described the PAILRED instrument, emphasizing the simplicity of a linear diffractometer which requires no computer or calculated angles. R. L. Beddoes (London) described the Hilger and Watts diffractometer and gave an account of its practical application. D. W. Beard (Cleveland, Ohio) dealt with crystal monochromators mounted in horizontal and vertical orientation and pointed out the relative merits of crystal reflected and filtered radiation. E. Curcio (Rome) described the GE diffractometer. A. J. H. Duisenberg (Holland) gave an account of the Nonius diffractometer and of some of the structural work carried out with it. E. R. Wolfel gave an account of two Stoe diffractometers. The first combines a Weissenberg photographic goniometer with a detector so that it becomes an equi-inclination diffractometer and the second is a four circle diffractometer with a special mounting for the X-ray tube. The last paper was given by H. Mayer (Germany), who described the Siemens four circle diffractometer, laying special stress on the accuracy of its mechanical construction.

More Allosterism

from our Molecular Biology Correspondent

IT has sometimes been difficult of late to avoid the disagreeable impression that the greater portion of biochemistry, if not indeed of chemistry, is gradually being engulfed by the allosteric hypothesis as particular cases of the universal truth. Among the all too large number of supposed allosteric phenomena in the current literature there is, however, an interesting group of articles on the enzyme aspartate transcarbamylase, which was studied by Gerhart and others, with the interesting upshot that the catalytic and regulatory sites occur on different sub-units.

This work has now been extended by Changeux, Gerhart and Schachman (*Biochemistry*, 7, 431 and 538, 1968), who have studied the binding of ligands to the protein and its sub-units. There are two catalytic and four regulatory sub-units, but it appears that four sites in all are present which will bind the substrate analogue, succinate, and four sites for the inhibitor, cytidine triphosphate (CTP). This situation can be accommodated by the capacious allosteric theory of regarding the enzyme as an isologous aggregate of four protomers (effective sub-units), each consisting of one regulatory sub-unit and half a catalytic sub-unit. In the intact protein, only the binding of succinate follows a sigmoidal saturation curve, so that the substrate sites evidently function in a co-operative manner. The reciprocal effect of substrate on inhibitor binding has also been demonstrated, uptake of CTP being partly reversed by succinate.

In the same issue of the journal, Gerhart and Schachman seek evidence for the conformational changes which are expected to accompany the attachment of ligands. It was in fact reported almost two years ago by Dratz and Calvin that the addition of succinate engenders in aspartate transcarbamylase a considerable change in optical rotatory dispersion which can reasonably be interpreted in terms of a difference in the content of α-helix. Gerhart and Schachman have, however, chosen a chemical approach—reactivity of sulphydryl groups. Reaction with mercurial leads to dissociation of the enzyme into its sub-units, but this turns out to be a co-operative process at intermediate stages of the reaction only intact unreacted and fully reacted dissociated species were present. The rate-determining factor is then the reactivity of the native enzyme (most probably in fact its dissociation into the reactive sub-units) and this can be measured Addition of the two substrate species, succinate and carbamyl phosphate, led to a large increase in the rate of reaction, which was partly annulled by the inhibitor CTP The substrates at the same time brought about a small diminution in sedimentation coefficient, which was again opposed by CTP From the absence of any dependence on enzyme concentration, it was surmised that the substrates induce a true change in frictional coefficient rather than a gross shift in dissociation equilibrium It does therefore appear that an appreciable structural change occurs when the substrates are attached Changeux and Rubin (*ibid*, 561) show that the experimental data can be satisfactorily fitted on the basis of the two-state allosteric model, such that the substrate binds only to one of the conformational isomers, the inhibitor preferentially to the other, and that in the absence of ligands the two states co-exist, with a four-fold preponderance of the catalytically active form

It is worth noting, as part of the discussion of allosteric mechanisms, an article by Sweeny and Foster (*ibid*, 561) in which a clear formulation is given of the generation of sigmoid binding curves by isolated catalytic sites The requirement is only that there shall be alternative reaction pathways to the protein–ligand complex Several such models are described Another interesting analysis of co-operative binding is given by Klapper and Klotz (*ibid*, 223) for situations involving an aggregation equilibrium in which the affinities of the associated and dissociated states for a given ligand differ Measurement of ligand affinities can be used to yield the equilibrium constant for the protein dissociation, and a striking application to the dissociation of haemerythrin is described

Symmetry of RNA Transcription

from our Cell Biology Correspondent

In 1966, Szybalski and his collaborators proposed that clusters of pyrimidine residues in DNA are somehow related to RNA transcription, possibly acting as initiation and termination signals for RNA polymerase At the time the evidence for this hypothesis was thin, and the theory itself may well be an oversimplification, but all the evidence obtained since is compatible with Szybalski's suggestion In the latest paper from Szybalski's laboratory, Summers and Szybalski (*Virology*, **34**, 9, 1968) report that more than 99·8 per cent of the T_7 and more than 99 per cent of the T_3 coliphage messenger RNA molecules that are made throughout the phage growth cycle are transcribed from only one of the two complementary strands of T_7 and T_3 DNA And the strand which is transcribed contains clusters of cytosine residues, while the strand that is not transcribed has neither cytosine nor thymine clusters

Summers and Szybalski used the DNA/RNA hybridization technique to study T_7 and T_3 transcription and the success of their experiments depended on their ability to separate the two complementary strands of T_7 and T_3 DNA They did this with the techniques that have been developed by Szybalski's group over the last three years for separating the DNA strands of phage and bacteria If one of the two strands of a DNA molecule contains more cytosine than the other, they can be fractionated by first heating the DNA to separate the strands, then binding a polyribonucleotide rich in guanine to the *C* rich strands, so increasing its density, and then separating it from the *C* poor strand in a caesium chloride gradient

Having separated T_7 and T_3 DNA strands in this way, Summers and Szybalski were able to show that all the messenger RNA made at both early and late times hybridizes specifically with the *C* cluster strand Control experiments proved that the two DNA strands are not self-complementary and that *C* poor strand is available for hybridization so that its failure to hybridize *m*RNA is not an artifact

Clearly only one strand of T_7 and T_3 DNAs, the one rich in cytosine clusters, acts as template for messenger RNA Similarly, Mamur and Greenspan (1963) reported that only the pyrimidine rich strand of phage *SP*8 hybridizes with *SP*8 *m*RNA Szybalski's group (Taylor, Hradneca and Szybalski, *Proc US Nat. Acad. Sci*, **57**, 1619, 1967) reported that both strands of λ DNA act as templates and this correlates well with the occurrence of pyrimidine rich clusters on both strands Also Habich *et al* (1966) found that although both strands of *Bacillus megatherium* DNA act as template for *m*RNA, the pyrimidine rich strand contains most templates And *m*RNA must also be transcribed off both strands of T_4 DNA because Streisinger *et al* (*J Mol Biol*, **31**, 607, 1968) have concluded from genetic experiments that the lysozyme and *r* II genes are translated in the opposite direction to T_4 head protein

Given the correlation between template function of DNA strands and their high content of pyrimidine clusters, it is tempting to speculate that *dC* or *dT* clusters act as initiation and possibly termination signals for RNA polymerase Two *in vitro* experiments with RNA polymerase support this speculation First, most *m*RNA made *in vitro* with *E coli* as templates has *A* or *G* at the 5′ terminus (Maitra and Hurwitz, 1965) Second, Chamberlain (1967) reported that when poly *dCdG* or poly *dTdA* are used as templates *in vitro*, RNA initiation and termination occur very frequently

What sort of signals can clusters of pyrimidines provide? Langridge (1967) found that synthetic double helical DNA with pyrimidines on one strand and purines on the other had slightly different structure from native DNA Summers and Szybalski suggest that this modified structure in the regions of native DNA with pyrimidine clusters could serve as a recognition region for RNA polymerase

Isoenzymes and Cancer

from our Medical Biochemistry Correspondent

It is now well known that lactate dehydrogenase (LDH) is found in five electrophoretically separable forms known as isoenzymes or isozymes The enzyme molecule is made up of four sub-units, each of which can be one of two types known as *H* and *M* sub-units The possible combinations of *H* and *M* sub-units give the five forms of LDH which can be separated by electrophoresis in suitable conditions

In a study of the LDH isozymes in normal human uterus, in myoma and in carcinoma of the uterine cervix, Okabe and co-workers (*Biochemistry*, 7, 79; 1968) have found, like many other workers working with many other kinds of tumours, that there is a preponderance of isozymes containing *M* sub-units in the malignant tissue from tumours. They found, for example, that the benign uterine tumour had an isozyme pattern very similar to the pattern in normal human uterus. They isolated the isozymes from the tissues and found that those from the malignant tissue showed a higher rate of reaction with nicotinamide adenine dinucleotide analogues than the other types.

An enhanced production of lactic acid from pyruvic acid (brought about by LDH) is the outstanding biochemical difference between malignant cells and normal cells. Indeed, when Warburg first discovered the high rate of glycolysis in tumours, he suggested that this was the cause of malignant growth. Opinion has recently tended to swing away from this theory, but there is now some evidence that the change in LDH isozymes may be one of the earliest alterations when a tissue becomes malignant and that this change in LDH may influence the rate of glycolysis.

In 1966, Latner, Turner and Way (*Lancet*, ii, 814, 1966) found that in specimens of pre-invasive carcinoma of the cervix obtained at operation, the amount of change in the LDH pattern seems to be correlated with the amount of tumour tissue. In some cases, however, the LDH pattern was changed even though there was no evidence of carcinoma when sections were examined. All the specimens must have contained some tumour cells, for cancer had been diagnosed from cervical smears. The LDH isozymes were changed before any change in the activity of lactate, glucose 6-phosphate or 6-phosphogluconate dehydrogenases was measurable.

Langvad (*Inter. J. Cancer*, **3**, 17, 1968) has now measured the ratio of LDH isozymes with M_3H_1 and M_1H_3 constitutions in samples from the tumour and from apparently normal colon of operation specimens from thirty-six patients with carcinoma of the colon. Each tissue sample was halved longitudinally, one half being used for the preparation of LDH isozymes and the other prepared for histological examination. The mean ratio for samples containing tumour tissue was 1·5–1·6, while the mean ratio for samples with no tumour tissue was 0·7–0·8. Usually the ratio decreased with distance from the tumour, but some specimens had local areas where the ratio rose considerably above 0·8 and approached the ratio found in the tumours. These patches where the ratio increased were often at considerable distances from the edge of the tumour. It is not unusual to find more than one primary tumour in patients with carcinoma of the colon, so these areas where the LDH ratio changes towards the tumour ratio may well be areas which will eventually become malignant. The change in LDH isozymes seems to occur before the tissue looks malignant, and may be one of the earliest detectable changes in a tissue which is developing a tumour.

Phage RNA Replication

from our Cell Biology Correspondent

FOR several years, there has been great interest in the mechanism by which the single-stranded RNA molecules of coliphage are synthesized. Weissmann's group (Feix, Pollet and Weissmann, *Proc. US Nat. Acad. Sci.*, **59**, 145, 1968) has now demonstrated that the minus strand RNA molecules of $Q\beta$ coliphage, which are inherently non-infectious, can serve as templates for the *in vitro* synthesis of $Q\beta$ plus strands. Last year Weissmann proposed that the minus strand—not a duplex molecule with plus and minus strands hydrogen bonded together—is the template for synthesis of progeny plus strands during the replication of the single-stranded RNA genome of $Q\beta$ (see *Nature*, **214**, 1287, 1967). Two observations supported this idea. First, some of the minus strands made *in vivo* in $Q\beta$ infected *E. coli* occur in a complex with molecules of replicase and with plus strands but are not hydrogen bonded to the plus strands. Secondly, neither of the two species of double-stranded RNA molecules—replicative form and replicative intermediate—which can be extracted with detergent and phenol from $Q\beta$ infected *E. coli* serves as a template for $Q\beta$ replicase *in vitro* unless it has been denatured by heat. The only way to test this hypothesis, however, was to isolate minus strands and investigate their template properties.

In November last year (see *Nature*, **216**, 639, 1967) Weissmann's group reported the isolation of pure $Q\beta$ minus strands. Now they have found that the minus strands do indeed direct a rapid synthesis of $Q\beta$ plus strands. In the presence of the four nucleotide triphosphates, $Q\beta$ minus strands promote rapid synthesis of RNA plus strands by $Q\beta$ replicase. In fifteen minutes the amount of RNA synthesized is three times the input of RNA, but with $Q\beta$ plus strands as template, less RNA and fewer infectious units are made. Furthermore, the enzyme is saturated by a much lower concentration of plus strands than minus strands and, at high template concentrations, incorporation into RNA is about seven times greater with minus strand than with plus strand templates. Feix *et al.* calculate that with minus strands as templates, a plus strand is made in about 100 seconds, which means that about 30 phosphodiester bonds are formed per second. These results are compatible with the assumption that the replicase preparation contains a small number of binding sites specific for plus strands and a larger number of binding sites specific for minus strands. Whether these two sites are on different sub-units of one protein or on two different proteins remains to be seen.

Spiegelman's group, unconvinced by the evidence obtained by others for the existence of a minus strand and its role in replication, has been doing experiments to convince itself. First, the group has satisfied itself that a minus strand exists and, in its latest contribution to the *Proc. US Nat. Acad. Sci.* (**59**, 141, 1968), Pace, Bishop and Spiegelman conclude that replicative form and intermediate, which they had chosen to call Hofschneider and Franklin structures, are in fact involved in $Q\beta$ replication and deserve their original names.

Also in the current *Proc. US Nat. Acad. Sci.* (**59**, 185, 1968), Nayak and Baluda describe the isolation, by phenol extraction, of replicative intermediate RNA molecules from chick embryo cells infected with equine influenza virus. Because replicative intermediates have also been found in cells infected with polio virus, it appears that all single-stranded viral RNA molecules are replicated by the same basic mechanism.

Action after the Dainton Reports

by
L. ROSENHEAD
University of Liverpool

What are the reasons for the swing away from science at sixth form level?

THE Interim Dainton Report of 1966 and the recent Dainton Report of early 1968 bring a number of national and educational issues into sharp focus. These issues have become dangerously acute for Great Britain within just a few years. The danger lies in the fact that while our national welfare has become increasingly dependent on engineering, technology and science, the percentage of "dedicated young scientists" entering the sixth forms has dropped from 41.5 per cent in October 1961 to 31.4 per cent in October 1966. This means that the science-based activities of society are rapidly losing favour among the brightest of Britain's young people, just at a time when our national economy has been experiencing crisis after crisis. This deliberate turning away from engineering, technology, science, medicine and related work will have far-reaching effects on recruitment to those sectors of our national activities which are dependent on science, and will aggravate the effects on society of the brain drain at high levels of expertise.

This situation has developed at a time when the relevant age groups are smaller than those of the bulge years that immediately preceded them, with the result that both trends have already combined to produce in recent years a substantial numerical decrease in the number of dedicated scientists in our sixth forms. While this has been going on, the sixth forms themselves have been growing in size, but the increase has appeared in groups interested in "the traditional arts", "socio-economic studies", "craft, domestic and commercial subjects" and, quite appreciably, in a mixed "science-with-arts" group. The increases are therefore appearing in sectors which, under present conditions of university entrance, make the members of those groups ineligible for admission to courses of instruction currently given in faculties of engineering, technology, science and medicine—even if they desired to enter those faculties. In addition, I have recently been told that appreciable numbers of the apparently dedicated scientists of our sixth forms are moving over to the study of economics when they enter universities.

From these facts there emerge a number of important issues. Should we welcome these developing trends, or should we passively accept them? Are they in the national interest? Will they lead to appreciable unemployment in the near future among a substantial proportion of our university-trained people? These are matters meriting very careful consideration and early decision. If we are concerned with the public welfare, we would do well to remember a telling phrase from the recent government "Brain Drain Report" (Cmnd 3417) which reads "... the source of national wealth is in the creative, productive industries of this country", and another from Professor J. K. Galbraith's recent book *The New Industrial State* (Hamish Hamilton) which goes "It is the vanity of educators that they shape the educational system to their preferred image. They may not be without influence, but the decisive factor is the economic system".

There is an unresolved conflict between the ideas of those who favour "a general education" and of those who stress the importance of adjusting educational curricula and procedures to meet the changing needs of society. In this conflict we are confronted not with a problem of right versus wrong, but with a problem of right versus right, and in such a situation there is only one way in which to move ahead, and that is by way of compromise—a middle way *must* be found. I welcome the increased vitality shown by secondary schools in increasing the range of studies in their sixth forms—by so doing they have induced large numbers of young people to remain at school and try their hand at advanced work. But this growth of our sixth forms is occurring largely among those who do not seem to want to turn to the science-based activities of society. What are the reasons for this? Are they connected with the pattern of education in schools? Or the specialized entrance requirements of universities? Or the ideas of young people about society generally?

Young people sometimes complain that they were not warned of the existence of university entrance requirements before they started on their sixth form work. One knowledgeable headmaster told me that he makes a point of meeting individual members of his sixth form before they start work, and of discussing their subject groupings. Those who have attached themselves firmly to either science or arts present little difficulty, but the mixed science-with-arts people are warned that they are cutting themselves off from science, though not necessarily from arts, social science or economics. They are also warned that they will probably have to make many enquiries before they find a university that will accept them. The fact that sixth formers are not automatically accepted by universities on the basis of any grouping of sixth form studies, and the quite demanding requirements of the science-based faculties of universities, are, in the opinion of some headmasters, important factors in the "swing away from science".

According to some people the swing away from school science has been reinforced by the siren-like lure of the word "management" and its implications, but I feel that the spurious part of this attractiveness will become evident in a very short time. I also believe that it will soon come to be recognized that a training in engineering or science, reinforced by instruction in economics, and the ideas and techniques of management services, is the best preparation for management activities and decision making.

The reasons for the nature of current university entrance requirements in engineering, technology and science are that science-based university courses are, in Great Britain, all highly intensive in one way or another. They are geared to the production of high-level specialists. The tempo of university work is fast, and the time is short. Science-based university studies bear the mark of recent additions to knowledge and understanding, and the studies are hard and demanding. In order to achieve the current academic level of an honours degree in 3 years our science-based faculties demand some previous knowledge of certain basic disciplines, and these demands are embodied in entrance requirements which vary from university to university in accordance with the specialist outlooks of different academic communities. As the boundaries between the traditional sciences are collapsing the effect is that university science-based faculties are broadening the range of their entrance requirements; a knowledge of physics and mathematics, for example, is being increasingly demanded. These requirements are not just whims—they are based on valid specialist attitudes to engineering, technology, pure science and medicine, and on one further condition. This condition is that, in England and Wales alone of all the countries of the world, the standard of a high-level university "first degree" has to be achieved in only

3 years—as a result of pressure imposed by the appropriate finance-awarding authorities. In order to meet this situation schools, of their own free will, and in order to prepare their students for university entrance, have in the past introduced specialization into their sixth form studies to a level that many people feel is in conflict with the requirements of "a desirable general education". It is in this way that continuing externally imposed financial pressure has transmitted specialization through universities into schools. But schools now say, in effect, that as a result of their shortage of science-specialist teachers they can no longer keep up the academic pace. At the same time the schools say that they wish to broaden the range of sixth form studies in the interests of general education. They also say that some of their sixth forms contain a growing proportion (up to three-quarters) of young people who have no intention of going on to university. But this is precisely the reason why extra attention should be paid to the needs of that diminishing group who wish to serve society as engineers, technologists, scientists, doctors, dentists, lawyers, specialist teachers, and so on.

There is, I feel, a simple way of meeting this situation. If more places were made available in our universities, and if 3-year and 4-year honours courses were run, in parallel, in all universities, as a matter of principle, then the intensive nature of present entrance requirements would automatically be relaxed, schools could drop some of their specialist intensive sixth form work, and could devote themselves to a more flexible pattern of instruction whose principal aims would be the development of character, curiosity and self-reliance—as well as an appreciation of the arts and the sciences. All that universities would then need to demand would be evidence of education, to agreed levels, over a range of subjects wider than at present—and this range would, it is hoped, span the "two cultures". In this way the need to make decisions at the age of about thirteen or fourteen, which drastically biases subsequent career choices, would disappear entirely.

But career choices, broad or narrow, cannot be postponed indefinitely. Young people do have to make decisions about themselves and the basic question is "When ?" I do not know the answer to this—except that it varies from individual to individual—but I am sure that young people should not be compelled to make such decisions at about the age of thirteen or fourteen when they know little of the challenge, motivations and objectives of the science-based activities of society. At the same time, if a young person shows that he really knows what he wants, then I would not attempt to impose on him the elements of a completely non-oriented education in place of the ingredients of an oriented one. Enforced dispersion of studies may be quite as inflexible and as harmful as enforced concentration of studies. Education for living should not be planned on too many preconceptions, though some may, of course, be necessary. And, above all, flexibility of approach, within reasonable limits, should be the hallmark of our educational system. I feel it reasonable to expect that, if up to the age of about sixteen a young person has been exposed to stimulating, thought-provoking instruction, it should reinforce his out-of-school experience to such an extent as to produce in him some kind of career motivation, broad or narrow, and that by the age of about eighteen the career-decision should be, if not firm, then at least more sharply defined than at sixteen. This means that instruction between sixteen and eighteen should be more broadly based and less intensive than at present.

Even under my own private vision of a desirable pattern of further education, however, I can offer no guarantee that there will result a reversal of the current swing away from science, technology, engineering and medicine in our secondary schools. That is quite a different matter. A decision has to be taken "somewhere" that such an objective, the reversal of the swing, is in the national interest—and this is clearly a matter for highest governmental levels—and appropriate action has then to be set in train. To me it seems that the continuation of the expansion of our universities without some reference to national needs is bad policy and potentially very dangerous.

But before any action is taken the reasons for the swing away from science have to be diagnosed and brought into the light of day by enquiry, discussion and speculation—and the Dainton reports are important in this context in that they open the debate. Mr J. R. Butler's survey of literature on "Occupational Choice", which is mentioned in the report, is both fascinating and highly relevant. Changes in the current programme of education at primary, secondary and tertiary level are fundamental in order to enable our young people to make a "more informed career choice" than at present, but which way the informed choice will direct itself will depend on other matters. If our young people continue to regard industrial employment as they now appear to do, and if the teaching of science, arts and economics continues as at present, then the effect of postponing career-decisions may well be to accelerate the flow away from engineering, technology and science.

It is, I feel, very important that we find out what our young people are thinking about the world, Great Britain and themselves, of course we cannot hope to obtain clear and precise answers—probably nobody ever makes decisions about the future on the basis of clear and precise views—but even answers of a general nature might help us to understand. Of one thing I am sure, and it is that the "image of science" is no longer as exciting as it used to be. Very few of our young people see themselves as making world-shattering scientific discoveries in a small laboratory, isolated from the rest of the world. Science is no longer thought of as the harbinger of the new society, or the vital instrument in the creation of a future in which all men will be brothers. Science, they feel, leads to "the bomb", to bigger and faster aeroplanes, to gigantic electricity-generating stations, to computers of frightening flexibility and complexity, to submarines, to intercontinental ballistic missiles—and to the insignificance of individuals and themselves. This picture is distasteful to many, and positively repellent to some of our young people, but it is based on a false image of science and all that engineering, technology and science can do for people. Further, this attitude towards science, and to developments from it, has arisen in all the other highly technological societies of the world, both in schools where science teaching is said to be "good" and in those where it is said to be "bad". In the underdeveloped countries of the world, however, science still wears its bright and shining appearance. I believe that it is by making employment in science-based industries attractive, and by appealing to the idealism that is endemic among our young people, that we can repair and refurbish the image of science, and point to the excitements of scientific discovery, and to the service that they, the young people, can render to society and to the underdeveloped countries of the world by becoming engineers, technologists and scientists. In this context, both teachers and industry have a great deal of imaginative work to do to make science-based activities more attractive to our young people, and to make the social purposes of industry more understood. In spite of all that we have done, we still have only *started* to explore space, to understand the nature of matter, to probe the mysteries of the stars, the air, the land, the sea, to conquer the deserts and control the weather, to make two blades of grass grow where only one grew, to extend life and to increase vigour into old age—and to banish hunger, want, homelessness and fear from the world Engineering, technology and science still remain potent forces for good in planned social change

No one line of action will reverse the swing away from science Government, schools, universities and industry will all have their parts to play—and they will have to act in harmony At about the beginning of this century people in authority in Great Britain came to the conclusion that we were suffering from a pronounced lack of "educated manpower", particularly in science and engineering, and the universities of Great Britain were enlarged as a result of this realization Now, at the beginning of the final third of the twentieth century, we are confronted by challenges which are clearly outlined and clarified by the Dainton reports Perhaps the most fundamental of the challenging questions to be answered are these What have we to do to make the science-dependent activities of society more attractive to the brightest of our young people? How, through our educational system, can we influence our young people to turn to engineering, technology, science, medicine and so on? And how can we induce, through our educational procedures, an appreciation not only of human values in isolation, but also of engineering, technology and science in relation to human aspirations?

The State of Public Science

by

Sir SOLLY ZUCKERMAN

The following is an extract from the speech given by Sir Solly Zuckerman, Chief Scientific Adviser to the British Government, and chairman of the Central Advisory Council for Science and Technology, to the Parliamentary and Scientific Committee

It is no exaggeration to say that today our public institutions for dealing with science and technology are passing through a phase of rapid evolution as they adapt—not without struggle—to the facts of the scientific and technological age in which we are immersed

The basic pattern which is now being transformed was set during the period of the First World War, to meet contemporary needs as seen at the time not only by politicians, administrators and industrialists, but also by scientists The problem as then defined was to place the responsibility for our national research institutions in the hands of a minister who was free from the pressure of administrative duties and who was therefore—so it was assumed—"immune from any suspicion of being biased by administrative considerations against the applications of the results of research". What happened—not surprisingly—was that the research council system which emerged out of this presumed principle of scientific independence—like the university world with which it became mainly associated—exercised little influence on the policies of those government departments which were concerned with related technological matters

If we are to continue as a powerful nation in the new world of industrial competition, it is my view—contrary to what Lord Haldane's committee supposed—that the applications of the results of scientific enquiry must necessarily be biased by political and administrative considerations It is in the light of this proposition that I feel that we should judge the major changes that have taken place in our public scientific institutions over the past three to four years, and of further changes which I see inevitably following in the years ahead

The basic fact that we have to bear in mind is that up to the Second World War, little more than twenty-five years ago, we in the United Kingdom not only covered but almost defined the nature of the water front of world science and technology Against the massive deployments of the USA and USSR, the technological resources we can mobilize now cover only a small part—although there is still a powerful tendency to spread ourselves too widely and too thin Our problem—like that of Europe as a whole—is to select, and to concentrate our scientific effort The challenge before us is to achieve a sophisticated view of the priorities for the deployment—during the next ten or twenty years—of our scientific and technological resources

The reorganization in the machinery of government of the past few years has brought into being the Ministry of Technology, a series of advisory bodies, and Parliament's new Select Committee on Science and Technology

The Ministry of Technology has quickly, and not surprisingly, grown into a major enterprise and has now become the principal department concerned, in the interests of the economy as a whole, with the problem of helping industry make as much use as it can of the fruits of modern technology These are early days, and those who are sometimes impatient with the progress of the new ministry forget the immensity of the task of shifting the focus of the Government's direct and indirect technological efforts from defence projects on to economically productive fields The Ministry has had to carry on with at least half the functions of the old DSIR, it has had to learn how to stepfather the AEA and NRDC, as well as emerge as the sponsor of the engineering, electronic and shipbuilding industries And, finally, and most arduous of all, it has had to become the manager of all the remaining functions of the old Ministry of Aviation

Experience will determine which way the ministry organizes the activities of the research and development establishments it inherited for the benefit of the industries whose efficiency it has the responsibility of fostering I have little doubt that industry itself will help determine what the right pattern of co-operation in research and development should be

We should treat the so-called Haldane principle of 1918 as a warning to be on our guard lest current arrangements and practices become codified into some new set of presumed principles The scale, the structure, the methods, and the directions and economic impact of industry change as technology changes—and no one benefits if the Whitehall machine fails to react in reciprocal fashion.

The same needs to be said of the network of advisory committees of independent scientists which characterize the Whitehall scene—although here I am bound to say, from personal experience, that there is little need to worry During the past twenty-five years or so, I have served—at one time or another—on most of these bodies They have changed so fast that many no longer exist What is perhaps surprising is that the fact that they did exist is often not known to their successors, whose footsteps then cover ground that has been well trodden before. Depending on the way you look at it, parliamentarians have an advantage here. Hansard is bound for future reference, but old advisory committee papers are normally burnt.

Two of the more significant changes of the past four years in this field are, first, the transformation of the old Advisory Council for Scientific Policy into today's Council for Scientific Policy, to which the Secretary of State for Education and Science turns for advice about the scale of resources required by the four research councils answerable to him, and about the division of the resources which the Treasury makes available and, second, the establishment of a new Central Advisory Council for Science and Technology, of which I have the honour to be chairman.

This body, which is answerable through the Prime Minister to the Government as a whole, was set up little more than a year ago, not to oversee the deliberations of departmental advisory bodies such as the Council for Scientific Policy or the Advisory Council on Technology, which was set up by the Minister of Technology, but to consider how best all the scientific and technological resources of the country can be deployed in the long-term national interest. We have not yet reported publicly, but our enquiries are proceeding apace, sometimes into questions of organization—on which, of course, we can only advise—but more frequently into matters which represent the core of our remit. For example, we want to uncover the factors which modulate the process of technological innovation, whether in industry or agriculture, we want to see whether criteria can be defined in order to help guide government investment in development projects, and we want to provide an intelligent appreciation of the likely priorities for our scientific and technological resources over the next ten years.

This leads finally to what I see as an extremely significant development in our national institutions for assuring the best deployment of our resources—the establishment of the Select Committee on Science and Technology, a development which the Parliamentary and Scientific Committee, so I understand, did much to foster.

I have read a fair amount of the literature—including the record of parliamentary statements—which deal with the formation of this new Select Committee, and I have also referred to the exhaustive report on nuclear energy which it has published. Considering the short time it has been operating, the impact of this new body has been formidable, and I have no doubt at all that it will increase even more, and that the committee will become a powerful force in the process of determining national policies.

A distinguished scientific writer, commenting on the Select Committee in an article which also dealt with the new Central Advisory Council for Science and Technology, remarked that "with any luck the two bodies will do their jobs so well that they will come into open conflict"—as the servants of the executive (that's where my council comes in) and of the legislature properly should. So far this has not happened, and I myself doubt—somewhat regretfully—that it ever will. What is certain is that the country at large, and departmental scientific advisory bodies in particular, cannot fail to benefit from the enquiries of the new Select Committee—whether or not they agree with its conclusions.

My main reason for saying this is that, however carefully the Select Committee has to tread in defining and agreeing its fields of enquiry with government departments, its proceedings are open and public. It has the power to invite—which is a polite way of saying summon—before it what witnesses it wishes to interrogate—ministers, government officials or private individuals, and "strangers" are not debarred—unless the committee so decides—from attending the sessions. This is a highly interesting departure. The committee will, I understand, not be concerned with matters which are within the arena of party controversy. But any issue of policy is controversial within the field with which it deals—otherwise it would not be debated—and among the "strangers" who listen may be potential witnesses who would be heard on some later date. As we all know, there is a lot of inertia—indeed, vested interest—in scientific and technological affairs, and interest is all the more likely to become vested if it is fostered behind locked doors.

This could help significantly in creating an informed climate of opinion about a great deal which now seems obscure. This applies as much to scientists and engineers as to industrialists, members of the public and parliamentarians. There are many issues relating to the exploitation of advanced technology which could only benefit from a greater public understanding. Not all advances are necessarily in the public interest. Industrial and commercial progress, as we are often reminded today, sometimes entails a not-immediately discernible social cost (and I am not just talking about matters like pollution here). Scientists and engineers themselves do not always appreciate this fact when it comes to advocating one of their specific projects. Furthermore, the point I made at the outset, that we can no longer attempt to cover the whole scientific and technological waterfront—however long ago this fact was clearly enunciated—is never, in my experience, appreciated when it comes to catering for particular interests. Here, too, the Select Committee could help, through its enquiries, to jerk us into the competitive realities of today from the delusions of a past grandeur, and to emphasize the need to select and concentrate our technological efforts—and those of Western Europe too. I can think of other ways it can and will help as it evolves through practice.

Excited Electronic States of Benzene and Naphthalene

by

J. B. BIRKS*
L. G. CHRISTOPHOROU
R. H. HUEBNER†
Health Physics Division,
Oak Ridge National Laboratory,
Oak Ridge, Tennessee

The excitation of the singlet and triplet π-electronic states of benzene and naphthalene by photons and by electrons is discussed in the light of recent experimental results, and suggests new techniques for the observation of these excited states.

PARISER[1] has characterized the ground and the singly excited π-electronic states of aromatic hydrocarbon molecules by three properties: multiplicity (singlet or triplet), symmetry (benzene A_{1g}, E_{2g}, B_{1u}, B_{2u} or E_{2u}, naphthalene A_g, B_{1g}, B_{2u} or B_{3u}), and sign (plus or minus in the linear combination of the molecular orbital configurations). The corresponding selection rules for electric dipole transitions are (*a*) multiplicity $1\leftrightarrow 1$, $3\leftrightarrow 3$; $1\leftarrow||\rightarrow$, (*b*) symmetry $g\leftrightarrow u$, $g\leftarrow||\rightarrow g$, $u\leftarrow||\rightarrow u$, (*c*) sign: $-\leftrightarrow +$; $-\leftarrow||\rightarrow -$, $+\leftarrow||\rightarrow +$

† Radiological Health Physics Fellow, University of Tennessee, Knoxville.

The observed optical absorption transitions in benzene and naphthalene and their probable assignments are listed in Tables 1 and 2. The assignments of some of the states in the Platt free electron orbital model[2] are shown in parentheses. The ground state is ${}^1A^-_{1g}$ for benzene and ${}^1A^-_g$ for naphthalene (see, for example, ref. 3, this was incorrectly assigned ${}^1A^-_{1g}$ in ref. 1), and so the selection rules give allowed transitions to ${}^1X^+_u$ states (where X represents any specific symmetry type), but some forbidden transitions to ${}^1X^-_u$ and ${}^3X^+_u$ states are also observed. The lowest excited triplet state, which is ${}^3B^+_{1u}$ and ${}^3B^+_{2u}$ in benzene and naphthalene, respectively, may be populated by flash photolysis and allowed absorption transitions occur from there to ${}^3X^-_g$ states. The observed emission transitions (fluorescence and phosphorescence) are also included in the tables.

Electronic transitions in these molecules with electron excitation have been observed[4,5]. Tables 1 and 2 list optical data and the maxima observed in the threshold electron excitation spectrum of benzene and naphthalene[4] and their probable assignments. Included in Table 1 are the maxima from the electron energy loss spectrum of benzene for 300 V incident electrons[5].

The importance of low-energy electron impact spectrometry for the study of electron excitation, temporary negative ion formation and electron capture processes in molecules has been pointed out previously[22]. With low energy electron excitation the multiplicity selection rule (*a*) is relaxed because of electron exchange, as long as the incident electron energy E is not too high. Thus several singlet–triplet transitions have been observed in He($E\leqslant 50$ eV)[23], N_2($E\leqslant 15.7$ eV)[24], H_2($E\leqslant 15.7$ eV)[25], CO($E=30$–60 eV), CO_2, N_2 and He($E=50$ eV)[25]. For a number of larger molecules, however, no singlet–triplet transitions have been observed with electron excitation[26] at $E\geqslant 35$ eV. This indicates that for polyatomic molecules, such as the aromatic hydrocarbons, the incident electron energy E needs to be close to the threshold for the efficient excitation of a singlet–triplet transition. The three singlet–triplet transitions in benzene, which are observed with threshold electron excitation[4], are not detected with 300 V electron excitation[5], although the allowed singlet–singlet transitions are observed in both cases. This confirms that the electron impact excitation function for singlet–triplet transitions is a strongly peaked function of E near the threshold.

Three relatively strong minus–minus transitions are observed with threshold electron excitation, showing that the sign selection rule (*c*), which is also violated with photon excitation, is not stringent, probably because of vibrational interaction.

No *g*–*g* transitions are observed, indicating that the symmetry or parity selection rule (*b*) is valid with both high-energy electron and photon excitation. For low-energy electrons, however, *g*–*g* or *u*–*u* transitions may be weakly observed because of the impacting electron's form factor. Electric quadrupole *g*–*g* transitions have been observed both optically[27] and by electron impact[28], but such transitions are extremely weak, with a transition probability of only 10^{-8} that of an allowed electric dipole transition[27].

Threshold electron excitation of the ${}^1A^-_{1g}$ ground state (${}^1A^-_g$ for naphthalene) gives transitions to ${}^1X_u$ states, as with photon excitation, and also to ${}^3X_u$ states. Population of the lowest triplet ${}^3B^+_{1u}$ by flash photolysis gives allowed optical transitions to ${}^3X_g$ states, so that the two techniques of triplet excitation are complementary[29].

The only unidentified states in benzene below the ionization potential are ${}^3E^+_{2g}$, ${}^1E^+_{1g}$ and ${}^1E^-_{2g}$ with theoretical energies of 5.96, 8.20 and 8.36 eV, respectively[1]. Dipole transitions to these states from ${}^1A^-_{1g}$ are forbidden by selection rule (*b*). The ${}^3B^+_{1u}\rightarrow{}^3E^+_{2g}$ transition has not yet been observed by flash photolysis.

The states in naphthalene with theoretical energies[1] less than ~ 6 eV that have not yet been positively identified are the three *u*-states—${}^3B^+_{1u}({}^3B_b)$, 3.64 eV; ${}^3B^-_{3u}({}^3L_b)$, 4.02 eV, and ${}^3B^+_{2u}({}^3B_a)$, 4.22 eV—and the five *g*-states—${}^3B^+_{1g}$, 3.42 eV, ${}^3A^+_g$, 4.44 eV, ${}^1B^+_{1g}$, 5.51 eV, ${}^1A^-_g$, 5.73 eV, and ${}^1B^-_{1g}$, 5.98 eV.

Excluding the forbidden transitions to the *g*-states, the three *u*-states are candidates for the unidentified state X corresponding to the peak at 5.4 eV in the threshold electron excitation spectrum of naphthalene[4].

The ${}^3L_b$ state in benzene is observed at ~ 5.4 eV in the threshold electron excitation spectrum, and the corresponding state is therefore expected to have a rather lower energy in naphthalene. This seems to exclude the identification of X with ${}^3B^-_{3u}({}^3L_b)$. The ${}^1A^-_g\rightarrow{}^3B^-_{3u}$ transition in the threshold electron excitation spectrum of naphthalene is probably obscured by the strong ${}^1A^-_g\rightarrow{}^1B^+_{2u}$ transition.

The theoretical energy[1] (2.18 eV) of the lowest ${}^3B^+_{2u}$ state in naphthalene is 1.02 eV below the observed peak at 3.2 eV in the threshold electron excitation spectrum which is definitely assigned to the transition to this state. Addition of 1.02 eV to the theoretical energy of the second ${}^3B^+_{2u}$ state gives a predicted energy of 5.24 eV for the corresponding peak in the threshold electron excitation spectrum. DeGroot and Hoytink[20] have made improved calculations of the separations of the triplet states of naphthalene. Their value of 2.13 eV for the theoretical separation of the two lowest ${}^3B^+_{2u}$ states is a little higher than that of 2.04 eV obtained by Pariser[1]. Assignment of the 3.2 eV and 5.4 eV peaks in the threshold electron excitation spectrum to transitions to the two lowest ${}^3B^+_{2u}$ states, respectively, gives an observed separation of 2.2 eV, which agrees closely with the theoretical value of 2.13 eV. It appears reasonable, therefore, to assign X to the second ${}^3B^+_{2u}$ state. The state ${}^3B^+_u$ was not considered as a candidate for the X state because it is theoretically predicted[1] to lie too low in energy (3.64 eV). Furthermore, the ${}^3B^+_{3u}$ state is most likely associated with the peak around 3.6–4 eV observed in the threshold electron spectrum[4].

Additional support for the identification of the X state in naphthalene as the second ${}^3B^+_{2u}$ state comes from a comparison of the spectral resemblance between benzene and naphthalene[11]. If in going from benzene to naphthalene the degenerate triplet states ${}^3B_{a,b}$ in benzene split in the same way as the degenerate singlet ${}^1B_{a,b}$ states, then from the observed position of the ${}^3B_{a,b}$ states in benzene one concludes that the 5.4 eV peak in the naphthalene threshold electron spectrum corresponds to the energy of the second ${}^3B^+_{2u}({}^3B_a)$ state.

An experimental method has been proposed previously[20] for discriminating between singlet and triplet states excited by threshold electrons, and this is discussed more fully below.

An aromatic molecule excited into a higher singlet state internally converts, provided that it can lose its excess energy by collisions, to the lowest excited singlet state. It then either emits its characteristic fluorescence, undergoes intersystem crossing to the triplet manifold, or makes a radiationless transition to the singlet ground state. An aromatic molecule excited into a triplet state is similarly internally converted into the lowest excited triplet state. It then emits its characteristic phosphorescence, or undergoes radiationless intersystem crossing to the singlet ground state.

If the quantum efficiency of internal conversion is unity, as in most molecules in which competing dissociation processes do not occur, the fluorescence excitation spectrum $F(\bar{\nu})$ observed with threshold electron excitation will correspond to the singlet state excitation spectrum $S(\bar{\nu})$. Similarly, the phosphorescence excitation spectrum $P(\bar{\nu})$ will correspond to the triplet state excitation spec-

trum $T(\bar{\nu})$, plus a component $aS(\bar{\nu})$ of the singlet state excitation spectrum, where a is the quantum efficiency of intersystem crossing.

Experimentally, $F(\bar{\nu})$ should be the more readily observable of the two luminescence excitation spectra. Comparison of $F(\bar{\nu})$ with the total threshold electron excitation spectrum, the photofluorescence excitation spectrum and the optical absorption spectrum of the vapour would discriminate between singlet–singlet transitions and singlet–triplet transitions or negative ion resonances, and it would provide data about relative excitation cross-sections and about any deviations from Vavilov's law (fluorescence quantum yield independent of excitation energy), such as have been observed in benzene[30,31], alkyl benzenes[30,31], and alkyl naphthalenes[31]. To ensure efficient internal conversion, the vapour pressure needs to be high enough for sufficient collisions to occur within the molecular fluorescence lifetime (~20 ns for benzene, ~80 ns for naphthalene) to dissipate the excess excitation energy before emission.

Photon and threshold electron excitation of the $^1A^-_{1g}$ ground state gives transitions to $^{1,3}X_u$ states. The population of the lowest $^3B^+_u$ triplet state by flash photolysis enables allowed transitions to ^3X_g states to be observed. The one group of excited states that cannot be observed by existing techniques, because of the symmetry selection rule (b), are the ^1X_g states. An experimental method for the observation of such states is proposed, namely, the population of the lowest excited singlet state by flash photolysis and the observation of the transient singlet–singlet absorption spectra during the lifetime of the excited singlet state. The lowest excited singlet states in benzene, naphthalene, anthracene and the higher polyacenes are u-states, and allowed optical transitions from these states to higher ^1X_g states can occur.

Recent advances in pulsed laser technology have made feasible the singlet-state flash photolysis of the polyacenes. Experiments are in progress at the University of Manchester with a pulsed nitrogen laser which yields recurrent intense flashes of near ultraviolet radiation of 20 ns duration, and it is proposed to use this source for the singlet-state flash excitation of aromatic hydrocarbons and the observation of transient singlet–singlet transitions The technique is also applicable to the study of higher excited singlet states of excimers

Proton Magnetic Resonance and the Helix–Coil Transition

by

College of Technology,
Portsmouth, Hampshire

The molecular weight of polypeptides has a marked effect on the nuclear magnetic resonance manifestation of the helix–coil transition The technique can be used for absolute determinations of helix contents and compared with optical rotatory dispersion data.

WE have suggested that the changes in the nuclear magnetic resonance spectra of polypeptides through a helix–coil transition would depend on the nature of the side-chain and also on the molecular weight of the polymer[1] A comparison of the available data on different polypeptides[2–8] demonstrates that the nature of the side-chain has a marked effect on the nuclear magnetic resonance manifestation of the helix–coil transition This article reports the effect of molecular weight variation on the nuclear magnetic resonance spectrum of poly-γ-benzyl L-glutamate and demonstrates that in favourable circumstances an absolute estimate of helix content can be made

Of all the polypeptides so far synthesized, the polyglutamate esters have been subjected to the most intensive physico-chemical studies and as a result are the best characterized systems Doty and his collaborators[9] have shown for poly-γ-benzyl L-glutamate in dioxan and formamide that polymers with a degree of polymerization (dp) of 5 were completely random and with a dp of 13 were 44 per cent helical, concluding that a dp of between 7 and 14 was necessary for the onset of the helix form The five samples which we have used were synthesized by W E Hanby of Courtaulds, Ltd , and their properties are summarized in Table 1 The molecular weights of the three smaller samples [439*A* (1), (2), (3)] were determined from vapour pressure measurements using a Perkin–Elmer model 115 molecular weight apparatus, the molecular weight of the *R* 10 sample was determined from osmotic pressure measurements of *m*-cresol solutions using a Hewlett–Packard series 500 membrane osmometer (we thank Dr J C Haylock of the University of Exeter for this measurement) The molecular weight of sample *S P.* 18.4 was determined from its reduced viscosity measured in dichloracetic acid using the curve of viscosity against molecular weight obtained by Doty, Bradbury and Holtzer[10]. It has been shown that low molecular weight poly-γ-benzyl L-glutamate can form β-structures[11], and so the infrared spectra of chloroform solutions were recorded on a Grubb Parsons grating instrument, the 'Spectromaster' These showed that the lowest molecular weight polymer 439*A* (1) contained about 20 per cent of the β-form, the 439*A* (2) sample contained a negligible amount of β-material (< 2 per cent) and the other samples none It was assumed from this that β-structures would be absent in trifluoroacetic acid/deuterochloroform solutions of all samples except 439*A* (1)

Nuclear magnetic resonance spectra were recorded at 60 MHz on a Perkin–Elmer *R* 10 spectrometer using a computer of average transients to collect and average 128 spectra, at 100 MHz on the Jeol Co '*JNM*–4*H*–100' spectrometer and finally a few spectra were recorded on the Perkin–Elmer *R* 14 100 MHz instrument. The time

Table 1 POLY-γ-BENZYL L-GLUTAMATE SAMPLES

Sample No	Molecular weight	Average dp	β-Content in chloroform
439*A* (1)	1,480	7	~20 per cent
439*A* (2)	2,790	13	Negligible
439*A* (3)	4,490	21	None
R 10	20,100	92	None
S P 18 4	140,000	640	None

averaged spectra at 60 MHz were obtained from 1.5 per cent w/v solutions at 33.5° C, but spectra of 5 per cent w/v solutions were found to be identical. Thus for single scan spectra recorded at 100 MHz, 5 per cent w/v solutions were used throughout. The optical rotatory dispersion curves of the same solutions as used for the nuclear magnetic resonance studies were recorded at the same temperatures on the Bendix spectropolarimeter, 'Polarmatic 62', and were analysed using the Moffitt and Yang equation[12] to give the b_0 parameter. With our system a b_0 of $+70$ was obtained for the random coil form in trifluoroacetic acid and -630 for the fully helical form, and so the scale $(-b_0+70)/700$ was used to estimate the helix content by this method.

The nuclear magnetic resonance spectra of the poly-γ-benzyl L-glutamate of dp 92 in 8 per cent trifluoroacetic acid/92 per cent deuterochloroform at different temperatures are given in Fig. 1. The assignments of the resonance peaks are as follows: 1.83 τ NH in the helical form, 2.05 τ NH in the random coil form, 2.72 τ C_6H_5, 4.95 τ benzyl CH_2; 5.55 τ αCH of the random coil form, 6.00 τ αCH in the helical form, 7.55 τ, γCH_2 and at 7.75 τ the βCH_2 resonance peak. The polypeptide undergoes an inverted helix–coil transition as can be seen from the b_0 values in the caption, being largely helical at 50° C and almost random at 0° C. The solvent system is the same throughout, and so the changes observed in the spectra are a consequence of the conformational change occurring in the polypeptide. In agreement with Ferretti[4], two peaks are observed for both the amide NH and αCH resonances, there is also evidence of a similar behaviour for the βCH_2 peak at 7.8 τ, for there is an apparent upfield shift of 28 c.p.s. on going from the helix to the random coil form. It can be seen from the spectra that the two components of the αCH peak are well separated (50 c.p.s.) and of comparable width, while the components of the amide NH peak are separated by only 22 c.p.s., and, furthermore, the helical peak is wider than the component arising from the random form. For these reasons we prefer to use the αCH peak for conformational analysis. The changes in relative areas of the αCH proton peaks can be seen to follow the b_0 values of the solutions. The effect of polymer size on the behaviour of these peaks is shown in Fig. 2. The solvent compositions were chosen so as to give approximately 50 per cent helix (from optical rotatory dispersion measurements) for all samples. The nuclear magnetic resonance spectra were recorded at 60 MHz in identical conditions and it can be seen that with increasing molecular weight the two components of the αCH resonance peak broaden markedly on going from dp 13 to dp 92. For the largest polymer of dp 640, however, the two peaks are no longer observable and there is a broad single peak at an intermediate position. Furthermore, it can be seen that for the smaller polymers the areas of the two αCH components indicate approximately 50 per cent helix content and are thus in agreement with the b_0 values.

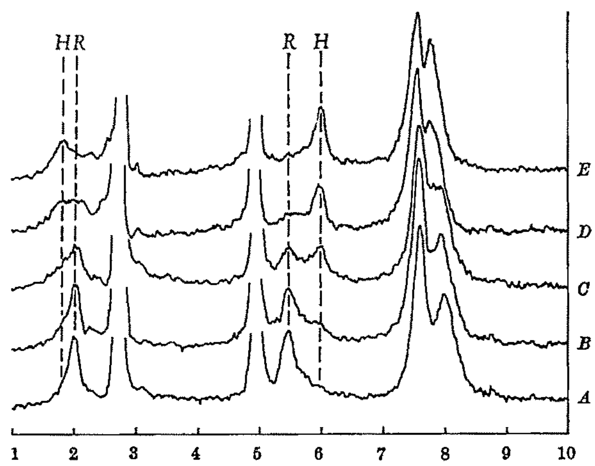

Fig. 1. Nuclear magnetic resonance spectra at 100 MHz showing the temperature induced helix–coil transition of poly-γ-benzyl L-glutamate, dp 92, in 8 per cent trifluoroacetic acid/92 per cent deuterochloroform. H, Helix, R, random. A, 0° C, $b_0=0°$; B, 6° C, $b_0=-100°$; C, 12° C, $b_0=-220°$; D, 25° C, $b_0=-340°$; E, 50° C, $b_0=-470°$.

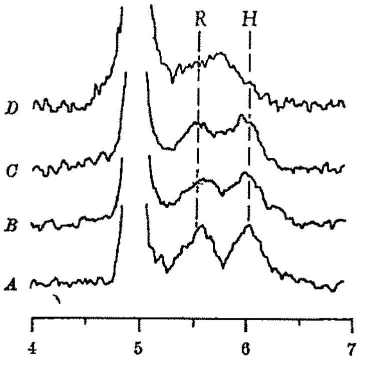

Fig. 2. Nuclear magnetic resonance spectra of poly-γ-benzyl L-glutamate at 60 MHz showing the effect of molecular weight on the components of the αCH peak. H, Helix, R, random. A, dp 13, $b_0=-305°$; B, dp 21, $b_0=-305°$; C, dp 92, $b_0=-285°$; D, dp 640, $b_0=-310°$.

At this point a more detailed study of the helix→coil transition in three samples of poly-γ-benzyl L-glutamate was undertaken at 100 MHz. The samples used were of dp 13, 92 and 640 to give a wide spread of molecular weights. The helix→coil transitions in the samples of dp 13 and 640 were controlled by increasing the trifluoroacetic acid content of the trifluoroacetic acid/deuterochloroform solvent system, while for the sample of dp 92 the temperature of the 8 per cent trifluoroacetic acid/92 per cent deuterochloroform solution was varied to give the inverted helix–coil transition. The results obtained for these polymers are given in Fig. 3a, b and c. There is little doubt from these spectra that, whereas two distinct and separate peaks are observed for the lowest molecular weight polymers, the polymer of dp 640 shows a single peak which is narrow for the random coil form, broadened at an intermediate position for the 50 per cent helical sample and very much reduced in area for the almost fully helical sample. It is evident, therefore, that the dynamics of the molecular motions are different for the highest molecular weight sample than for the smaller polymers.

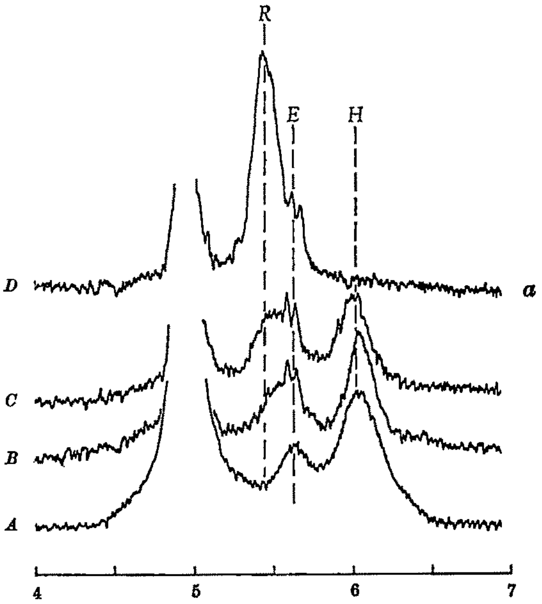
For the low molecular weight polymers the broadening of the two components of the αCH peak with increasing molecular weight is attributed to an increase in the overall correlation time of the molecule. As pointed out by Ferretti[4], the observation of two distinct peaks for the helix and random coil forms allows a lower limit for the lifetime t of the protons in the different conformations to be obtained from the inequality $t \geqslant [1/(2\pi|\nu_H-\nu_R|)]$ where ν_H and ν_R are the positions in c.p.s. of the peaks for the helix and random coil forms, respectively. For the αCH resonance the separation of the peaks is 58 c.p.s. giving $t \geqslant 2.8\times10^{-3}$ s. For the largest polymer, the 640 mer, the observation for the partially helical state of a single broadened peak intermediate in position between the positions of the peaks for the random coil and helix form indicates[13,14] that the polypeptide backbone protons are interconverting between the random coil form, which gives a sharp peak, and the helix form, which gives a much broadened resonance, at a rate which is faster than $2\pi|\nu_H-\nu_R|s^{-1}$. This gives a lifetime t for the proton in the helix and random coil forms as $t \leqslant 2.8\times10^{-3}$ s.

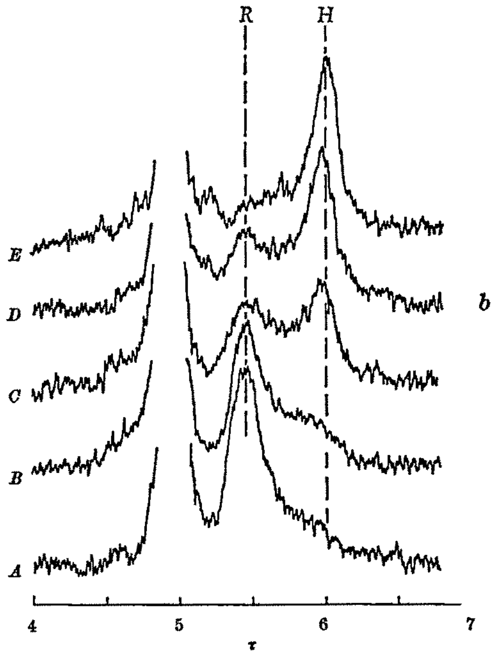
The observation of separate αCH peaks for the helix and random coil forms for the lower molecular weight poly-γ-benzyl L-glutamate allows an absolute determination of the proportion of the polypeptide in these forms

This is probably the only technique which permits an unambiguous determination of the helix content and can be used as an independent check on the use of b_0 for this purpose Ferretti[4] has pointed out that for poly-L-leucine and poly-β-methyl L-aspartate there is a correlation between the b_0 values and the area of the helical peak It is possible from the spectra given in Fig 3a and b to estimate the relative areas of the peaks for the two forms The overlapping curves were analysed by using the shape of the non-overlapped edges of the benzyl CH_2 resonance and the α*CH* resonance peak of the helical form to obtain the complete shape of the respective peaks By this method the scatter of results obtained was less than 5 per cent in the determination of the ratio

$$\frac{\text{area of the } \alpha CH \text{ helix peak}}{\text{total area of } \alpha CH \text{ peak}}$$

for the different solutions Fig 4 shows the inverted helix–coil effect for the polymer of dp 92 obtained from both optical rotatory dispersion determinations of b_0 and the contribution of the helical form to the α*CH* peak from the nuclear magnetic resonance spectra As can be seen, there is a very close correspondence between the two methods, a result which is in contradiction to that obtained by Stewart *et al* [3], who suggested from their nuclear magnetic resonance studies of poly-L-alanine that b_0 values gave a very poor estimate of helix contents A question which is of prime importance in the use of optical rotatory dispersion to estimate the helix content of proteins is whether the Moffitt–Yang equation holds for short helical lengths This question arises because Moffitt's original derivation of the equation[15] was based on considerations of helical chains of infinite length and it has been suggested that, for short helical segments, the value of b_0 would underestimate the number of residues in these segments[16], although certain theoretical considerations[17] suggest that most of the rotation characteristics of the helix are given by one turn of the helix The low molecular weight polypeptides used in this study allow a test of whether or not b_0 measurements hold for short helices In the sample 439*A* (2) of average dp 13, it could be expected that for chloroform solutions the average number of residues in the helices would be between 7 and 9 and for the sample 439*A* (3) of dp 21 in chloroform the average length of helical segments would include 15–17 residues, in trifluoroacetic acid/deuterochloroform solutions even shorter helical lengths would exist We have made an estimate from the nuclear magnetic resonance spectra of the proportion of residues in the helical form for these two samples and also for the polymer of dp 92 undergoing a temperature induced inverted helix–coil transition The ratios obtained were plotted against the helix contents calculated from b_0 values of the same solutions and this is shown in Fig 5 The broken line is that for a 1 1 correspondence and from a least square test this line is also the best fit to the experimental points





It is possible from the areas of the α*CH* peaks of the 13 mer and the 21 mer in chloroform to estimate the average number of residues not involved in the helix form and situated at the ends of chains. For both polymers this comes out to be two residues at each end A further point in connexion with these non-helical residues

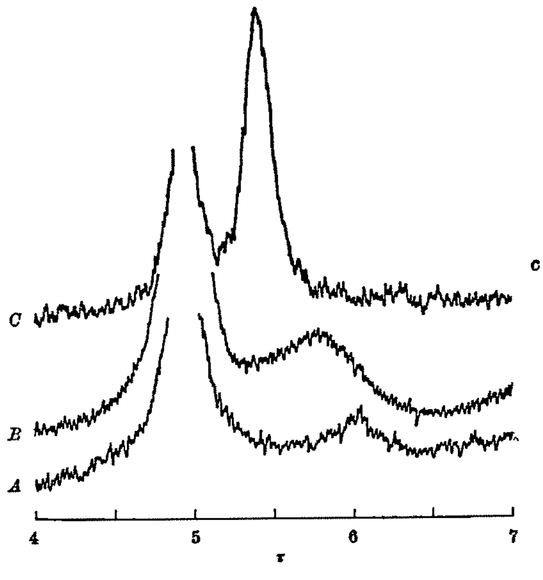


Fig 3 Nuclear magnetic resonance spectra of different polymers at 100 MHz showing the α*CH* peaks through the helix-coil transition *H*, helix, *R*, random, *E*, end groups

in chloroform solutions is, as can be seen from Fig. 3*a*, that the chemical shift of their α*CH* peak (5·60τ) is different from that of the random coil peak observed in 20 per cent trifluoroacetic acid/80 per cent deuterochloroform solution at 5·45τ. In the spectra of the solutions containing trifluoroacetic acid, however, there are also peaks at 5·60τ on the high field side of the main random peak which diminish with increasing molecular weight. It is thought that these higher field peaks result from residues at the end of the polypeptide chains and in the case of the chloroform solution these are the only residues which contribute to the random coil peak. Sternlicht and Wilson[18], however, have suggested that the α*CH* protons near the amino end of a helix may be shifted downfield by as much as 0·4 p.p.m. from α*CH* peak in an infinite helix. In the case given here the observation of the peak at 5·60τ for the fully random coil forms shows that it cannot have this origin. Furthermore, because the helical α*CH* peak in the spectra of the partially helical states of the dp 13 and 7 polymers in mixtures of trifluoroacetic acid and deuterochloroform has the same shift as the helical peak in the 92 and 640 mers, it is clear that residues on both ends of a helix have the same shift as those within long helical segments.

Concerning the difference in chemical shift between the random and helical components of the α*CH*, it has been suggested[1,6] that this may result from a specific interaction of trifluoroacetic acid with the helical regions of the polypeptide chain giving rise to a magnetic anisotropy not present in the helix itself and resulting in an upfield shift. This suggestion was made because it has been shown[7,19] that in water soluble polypeptides, poly-L-lysine, poly-L-glutamic acid[5] and copoly $(\text{glu}^{42}\,\text{lys}^{28}\,\text{ala}^{30})$, there is either no shift or only a very small shift in the α*CH* peak on going from the helical to the random coil forms. As shown here, however, the position of the peak for the helical form in deuterochloroform is the same as in the mixed solvents containing trifluoroacetic acid which indicates that the suggestion concerning the role of trifluoroacetic acid in this shift no longer holds.

The observation of a 0·6 p.p.m. chemical shift difference for the α*CH* peak of the random coil and helix forms differs from the result quoted by Sternlicht and Wilson[18] that there is no shift in this peak for poly-γ-benzyl L-glutamate. In this paper it is shown that there is a marked effect of the length of the polypeptide chain on the behaviour of the nuclear magnetic resonance spectrum in the helix–coil transition region. The behaviour of the low molecular weight samples confirms our earlier suggestion (ref. 1, case 2) that short polypeptide chains would have short overall correlation times and that this would lead to two components for the α*CH* resonance peaks having comparable widths for the helix and random coil forms. For the highest molecular weight sample the observation of a broadened time-averaged peak of intermediate position for the partially helical systems shows that the helical and random coil regions are interconverting at a rate faster than $360\ \text{s}^{-1}$. It is evident from this difference in behaviour between the various polymers that the rate of interconversion of the helix and random coil forms is dependent on molecular weight as well as on the nature of the side-chain. The much reduced apparent area of the α*CH* peak for the dp 640 polypeptide in 6 per cent trifluoroacetic acid/94 per cent deuterochloroform (which has an estimated helix content of 96 per cent from b_0 measurement) shows that for long helical segments the correlation time is insufficiently short to average out the magnetic anisotropy of the helix and considerable peak broadening occurs. This result is in contradiction to others[3,5], from which it was suggested that fully helical polypeptides give rise to well developed nuclear magnetic resonance spectra. As before[7] the width of the side-chain proton resonance peaks diminishes with increasing distance from the helical main chain.

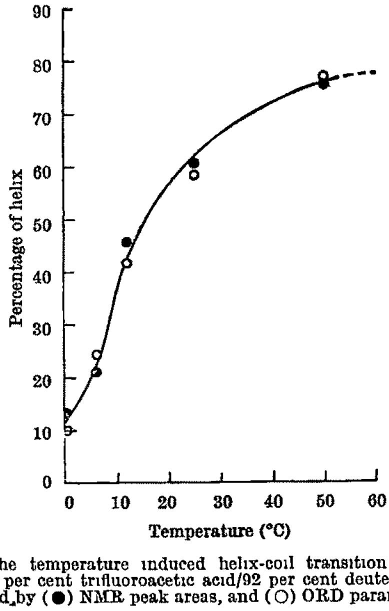

Fig. 4. The temperature induced helix-coil transition of polymer dp 92 in 8 per cent trifluoroacetic acid/92 per cent deuterochloroform followed by (●) NMR peak areas, and (○) ORD parameter b_0

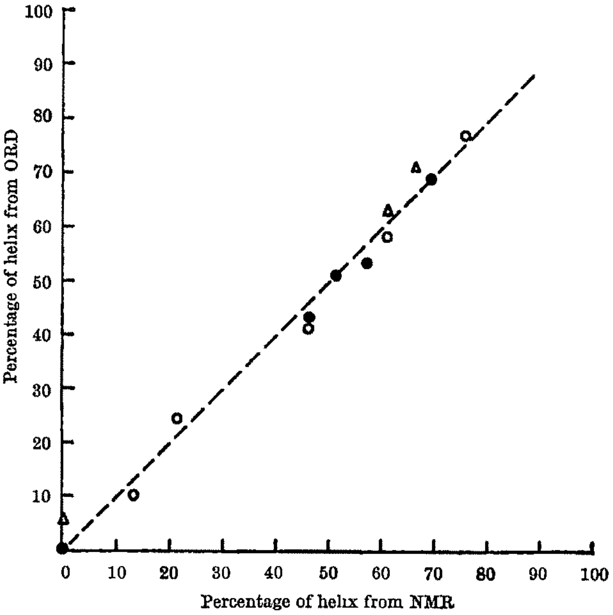

Fig. 5. The correlation of NMR and ORD estimates of helix content for three samples. (○) dp 92, (△) dp 21, (●) dp 13

Nuclear magnetic resonance spectra can give an absolute determination of helix content for two cases of polypeptide behaviour. The first is when the helix and coil regions are interconverting rapidly to give a single time-averaged peak, the position of which is proportional to the relative proportions of the two forms. For this case the estimation of helix content requires the resonance in the fully helical form to be prominent enough for its shift to be measured. Markley *et al.*[5] have used this method for the estimation of helix content. The second is the case elaborated here, where the appearance of two well resolved components for the α*CH* peak also allows an absolute determination of helical content and, furthermore, allows a test of the use of b_0 measurement for estimating the helix content in short helical lengths. The results from the polymer of dp 13 in deuterochloroform show that b_0 measurements of helix content are valid down to helical lengths involving eight residues and it is not unreasonable to suggest that because the correspondence also holds for the same polymer at lower helical contents in solutions of trifluoroacetic acid and deuterochloroform that b_0 measurements hold for helical segments involving fewer residues. From the point of view of biological applications of b_0 measurements to the determination of helix contents in proteins it is now reasonable to suggest that, provided there are no important contributions from side-chain chromophores or large proportions of conformations other than helical or random, a reasonable estimation of the helix content might be expected even if the helical segments are very short

We thank Drs M. Takeuchi and S Murakami of Jeol Co, Paris, for allowing us use of the Jeol *JNM-4H*-100 spectrometer, L. C Thomas for similar facilities, and Perkin-Elmer Co, Ltd, for use of their *R* 14 100 MHz spectrometer Two of us (H G and H W E R) thank the Governors of Portsmouth College of Technology for research assistantships The work is supported by the Science Research Council

Closed Continuous-flow Centrifuge

The first closed centrifuge has been developed in which it is possible to subject a mixture to an uninterrupted flow and a constant force field while collections of all components are being made. Practical applications of this device are considered

SITUATIONS often arise in the biological sciences when it is desirable to centrifuge large volumes to obtain relatively small fractions For example, the efficient separation of many blood components requires a system which permits removal of selected elements while returning most of the fractions to the donor In a continuous-flow centrifuge of small volume, large amounts of blood or other mixtures could be processed rapidly if it were not necessary to alter the force field or flow during the collection process

A recent collaborative effort of the National Cancer Institute and the Systems Development Division of the International Business Machines Corporation, Endicott, New York, has resulted in an effective, reliable, closed continuous-flow centrifuge primarily designed to separate whole blood into its individual cellular and fluid portions. This machine is the first closed centrifuge in which it is possible to subject a mixture to an uninterrupted flow and a constant force field while collections of all components are in progress. There have been many earlier attempts to develop such a centrifuge The first and remarkably effective approach was the development of the cream separator. In 1878 Carl Patrik Gustaf De Laval[1] of Sweden patented the first open, continuous-flow centrifuge, which not only revolutionized the dairy industry[2,3] but also represented the only completely continuous machine up to the present time

At the beginning of the Second World War there was a need for large quantities of human blood components In this emergency a 'De Laval' model *E*-19 cream separator was adapted by a group at Harvard, under the leadership of J Edwin Cohn, for the separation of plasma from whole blood[4] Subsequently, this machine has been modified and refined for the collection of plasma proteins and cells In making it a closed sterile system, however, the facility for continuous collection was lost[5] Other batch processing centrifuges have been described recently in which large volumes may be handled (Helixtractor Unit, International Equipment Co., Boston, Massachusetts, Continuous Action Rotor, Measuring and Scientific Equipment, Ltd, London), but to collect one of the components the centrifuge must be stopped One machine, a high speed density gradient centrifuge, deserves particular comment because it is capable of continuous flow processing[6] This machine permits high speed centrifugation but must be slowed down to unload the concentrated virus particles, hence the criterion of a continuous collection without alteration of the centrifugal field has not been fully achieved A simple lower speed batch separation centrifuge is reported by Barrett[7] of a method for the concentration of bilharzial meta-cercariae from infected water sources Although these batch separators are very useful, they are inefficient when the components to be separated, such as red blood cells and plasma, are of nearly equal volumes, or if a fraction intermediate in density between two principal components is to be collected

The NCI–IBM blood cell separator was designed to collect or return to the donor platelets, leucocytes, plasma and packed red cells The initial experience has been previously reported[8–10] and since then there have been many refinements in the design and materials

In 1962, shortly after the joint effort between the National Cancer Institute and International Business Machines Corp , Endicott, New York, was undertaken, a prototype centrifuge bowl was designed which consisted of meshed concentric cones This evolved into a device composed of three pieces fashioned of 'Delrin' (E I Dupont de Nemours and Co , Wilmington, Delaware) plastic in a truncated cone configuration The rotating face seal first used was modified from a design already in use by Anderson[11] Anderson's design consisted of a lower rotating half of 'Rulon' (Dixon Corporation, Bristol, Rhode Island), which is a 'Teflon' (E I Dupont de Nemours and Co , Wilmington, Delaware) TFE fluorocarbon compound, and an upper stationary half of stainless steel with a flame-plated tungsten carbide surface Both halves were lapped to a high degree of flatness and were spring-loaded against each other This design was modified by increasing the diameter and adding extra channels The stationary half was stainless steel which was hardened but not flame-plated Flatness was held to 30×10^{-6} in or less This design was not entirely successful and seal failure with resultant haemolysis occurred This problem was ultimately eliminated by the constant infusion of saline under pressure through tiny jets in the raised lands which separated the collecting channels (Fig 1) The 'Rulon' portion of the seal was temperature sensitive and changed shape with use The useful life of the steel–'Rulon' combination was found to be a maximum of 40 h and recently the 'Rulon' portion of the seal has been replaced by an extremely hard ceramic compound In contrast to the 'Rulon', the ceramic seal retains its flatness and has not shown wear after many hundreds of hours of use It is not sensitive to temperature changes.

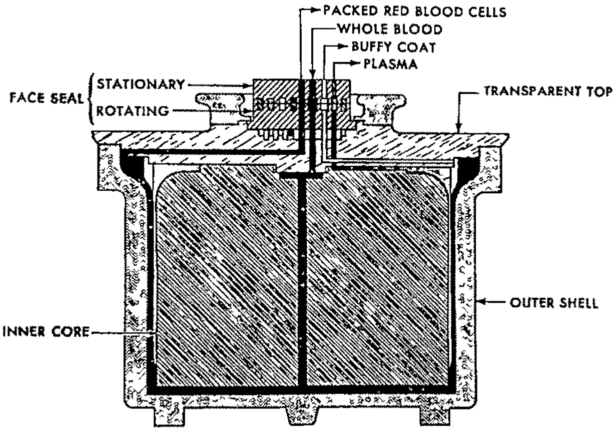

Fig 1

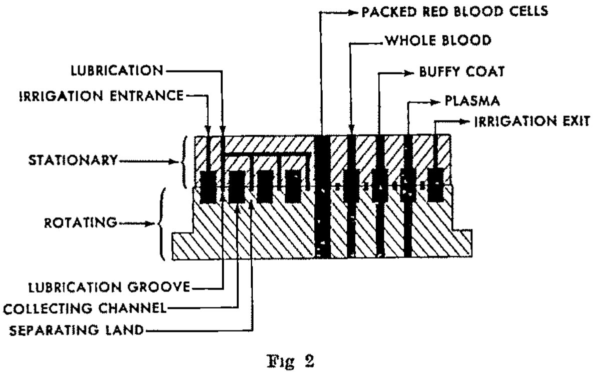

Fig 2

Various centrifuge bowl designs have been evaluated and the most successful, and the one currently used, is shown in Fig 2 This bowl, made of polycarbonate plastic, has a flow path 4 in long and 0 04 in wide with an effective radius of 2 5 in The effect of the length of the flow path on the ability of the centrifuge to separate was evaluated by processing 1-day-old ACD blood in bowls with 2, 3, 4 and 5 in flow paths As the flow was increased from 2–5 in at 50*g* and 40 ml /min flow rate the haematocrit in the red cell line increased from 54 per cent to 66 per cent and the plasma yield increased from 33 per cent to 56 per cent At *g* forces greater than 200, 85 per cent of the plasma was removed using the 4 in flow path bowl It was found that there was very little difference in separation efficiency among bowls with flow path widths of 0 020, 0 040 and 0 080 in

The present machine operates in the following manner blood from a reservoir, artery or vein enters the bowl through a stainless steel fitting in the stationary top half of the rotating face seal Blood then passes through the rotating face seal and down through a central passage in the solid inner core Blood moves peripherally at the bottom and then up the sides of the bowl into the flared portion of the top During this ascent up the sides of the bowl, separation of the blood components occurs Three exit ports, located in the clear bowl cover, permit collection from the bottom of the packed red cell layer, from the top of the plasma layer and from the plasma–red blood cell interface The flow of each separated fraction is controlled by peristaltic roller pumps which can be individually regulated by the operator The position of the buffy coat layer is controlled visually by varying the relative plasma and packed red cell flows The transparent cover allows the operator to observe the separation process and make appropriate adjustments in flow rate and *g* force to obtain the desired separation

Several biological problems are currently being investigated at the National Institutes of Health using the NCI–IBM blood cell separator The first is a study in dogs of the efficiency of buffy coat collection and the effect of centrifugation on the viability of cells[12] The second involves the collection of granulocytes from donors on a continuous flow basis *in vivo* for use in the supportive care of leucopenic recipients The third, an entirely different application, involves the infusion of large amounts of long chain free acids into dogs to study their effects on metabolism

A total of 160 centrifugations ranging from 1–12 h have been performed in dogs, using indwelling arteriovenous shunts[12] A maximum volume of 50 l of blood has been processed in a single centrifugation and a maximum flow rate of 12 l /h has been achieved. Leucocytes and platelets can be concentrated and collected in this system Within 2 h of centrifugation approximately one blood volume of leucocytes and platelets (24×10^9 and 197×10^9, respectively) can be collected in small volume (100 ml) with some red blood cell contamination (haematocrit of 10–15) Leucocyte and platelet concentrations of

$430 \cdot 0 \times 10^3$/mm^3 and $5{,}000 \times 10^3$/mm^3, respectively, have been obtained Up to 55 per cent of the leucocytes and 87 per cent of the platelets entering the centrifuge have been extracted Buffy coat preparations with a preponderance of either lymphocytes or granulocytes can be collected. Detectable damage to erythrocytes and lymphocytes has not been found to result from the centrifugation procedure Platelets seem to be sensitive, however, to mechanical and chemical factors associated with contacting surfaces and aggregation[12]

Preliminary studies in donors with chronic myelocytic leukaemia indicate that 30–60 per cent of the leucocytes entering the centrifuge can be collected in a small volume Donors have tolerated repeated centrifugation of up to 5 h without difficulty Leucocytes collected in this manner result in a rise in white blood count when transfused into acute leukaemia patients with drug induced leucopenia Recovery rates are comparable with those obtained with leucocytes processed by conventional plastic bag techniques

Fatty acid infusion studies in dogs have shown that long chain fatty acids, which result in haemolysis, thrombosis and death when introduced into the blood in the unbound state, are tolerated in large amounts when infused into plasma[13]. Bound to albumin, unesterified fatty acids are the chief form of lipid transport of the body When added to the plasma line of the cell separator before the plasma recombines with the red blood cells, a large quantity of concentrated free fatty acid may be infused into dogs without haemolysis The metabolic consequences of physiologically important quantities of fatty acids are being studied in this way. In addition, this technique provides a potential method for administering fat calories, including essential fatty acids, parenterally Up to 12 g of oleic acid, or nearly 100 calories/h, have been administered without difficulty to dogs of 12 kg

There are many areas of medicine and biological science in which an efficient continuous flow centrifuge could be useful Cells or large particles may be collected at low *g* forces as exemplified in the current use of the machine for the separation of the various cellular components in blood Other applications include the concentration of protozoa or parasites from water, blood or body fluids and the collection of bacteria from fluid culture medium The separation and collection of virus particles, chylomicrons and macromolecules are possible provided the machine is modified to operate at higher speeds The machine could be used for plasma exchange in a variety of clinical situations including hepatic coma, macroglobulinaemia, cryoglobulinaemia and so on, without the need for red blood cell exchange Preliminary work has already begun on a continuous-flow two stage procedure for the collection of platelet concentrates and the precipitation and removal of cryoglobulins Plasma dialysis could be carried out at conditions of pressure, *p*H or osmolarity that would be toxic to cellular elements in the blood

In summary, the evolution of an efficient reliable, continuous-flow centrifuge and its current use in the separation of blood cells in dogs and humans and in the study of fatty acid metabolism are described Possible practical applications of this device in other areas of investigation are outlined

Counts of Radio Sources at 2,700 MHz

by

J. G. BOLTON

CSIRO Division of Radiophysics,
Sydney, Australia

J V. WALL

Mount Stromlo Observatory,
Australian National University,
Canberra

Counts of radio sources from a 2,700 MHz survey made with the Parkes telescope for regions away from the galactic plane have shown a slope for the log *N*–log *S* relationship of –1 4. This is in strong contrast to the slope of –1 8 usually found in counts of radio sources at lower frequencies This low slope at 2,700 MHz throws considerable doubt on the often accepted hypothesis that the high slope for source counts at low frequencies is associated with an evolutionary decrease of the number density or of the level of emission of the radio sources or both.

PART of the motivation of the present survey came from the suggestion by one of us[1] that an alternative explanation of the high slope of the log *N*–log *S* curve may be found in the effects of the red-shift and the wide dispersion in radio source spectra

The survey was made with the 210 ft radio telescope and a new 2,700 MHz receiver[2] which has an input temperature of 80° K and an overall bandwidth of 200 MHz Peak-to-peak noise fluctuations with an output time constant of 2 s are 0 04° K, equivalent to 0 07 flux units The measured beamwidth of the telescope is 7 5 minutes of arc at 2,700 MHz The system can be operated with a backward-looking reference horn or an offset feed horn producing another 7·5 minute arc beam 18 5 minutes of arc off axis The latter mode was used in this survey and the difference between the signals in the on-axis and off-axis beams was recorded

The survey was made in two parts. The first covered an area of about nine hours of right ascension between declinations +4° and –4° and was surveyed by making scans at 2° per min in declination at intervals of 6 minutes of arc in right ascension. Within this region of 0.343 sr, all sources estimated to be stronger than 0.35 flux units were listed and subsequently re-observed for accurate position and flux density. The second part of the survey covered five selected areas of 40 square degrees each where there are two-colour (blue and ultraviolet) 48 in Schmidt plates to help in the identification of quasi-stellar objects. The total area covered by the five plates is 0.067 sr. Areas of 50 square degrees centred on the plate centres were scanned at 1° per min with scan intervals of 4.5 minutes of arc. The areas were scanned both in right ascension and in declination in order to reduce the possibility of confusion and to improve the signal-to-noise ratio. All sources estimated to be greater than 0.06 flux units were listed and subsequently re-observed for accurate position and flux density. As there is a bias in favour of detecting the stronger sources near the edge of any survey area, only sources within the smaller area of the two colour plates were used in constructing the log N–log S curve.

The purpose of making the survey in two parts with different levels of sensitivity was to provide source counts of similar statistical significance over a wide range of the log N–log S diagram. In the large survey area, 135 sources of flux density $\geqslant 0.4$ flux units were found and in the small survey area 210 sources of flux density $\geqslant 0.08$ flux units were found. The corresponding numbers per sr are 390 for the large and 3,100 for the small survey area. The composite log N–log S curve from the two areas is shown in Fig. 1. The straight line drawn through the observed points has a slope of -1.38, the statistical fluctuation errors would, however, allow limiting slopes of -1.30 and -1.50 to be fitted to the observations.

Confusion errors are believed to be negligibly small, because even for the five selected areas the number of effective beam areas per source is greater than 50. It is thought that errors due to angular extent and polarization of the sources are also negligible. Random errors of flux densities due to noise fluctuations are less than 0.02 flux units. Random errors of any kind will tend to increase rather than decrease the slope of the log N–log S curve.

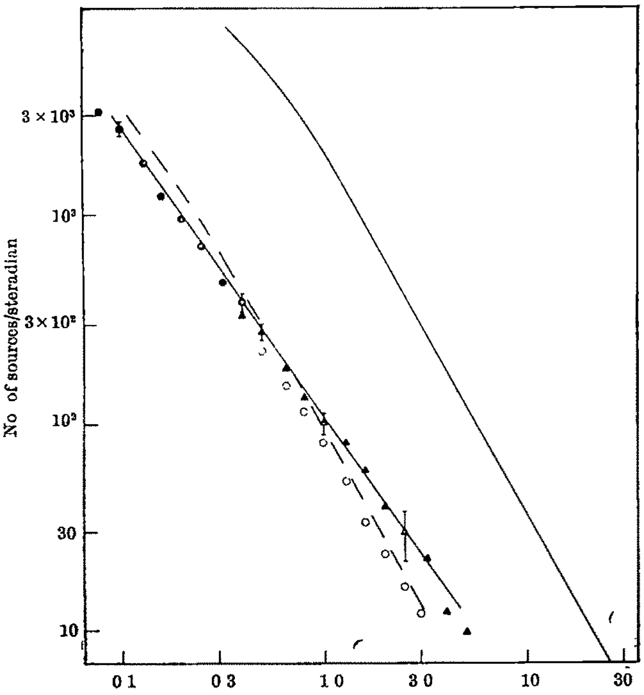

Fig. 1. Cumulative counts of radio sources as a function of flux density. ▲, 2,700 MHz survey of 0.34 sr; ●, 2,700 MHz survey of 0.067 sr; ○, counts of sources from the Parkes catalogue measured at 2,700 MHz. Solid line to right—counts from *3CR*, *4C* and *5C* surveys at 178 MHz after Gower. Dashed line is the expected count at 2,700 MHz obtained by convolving Gower's curve with the spectral index distribution for strong sources at 178 MHz.

In Fig. 1, the 2,700 MHz survey results are compared with source counts from the Parkes catalogues and the Cambridge catalogues. Data from the former, which were compiled at 408 MHz, have been restricted to about half the area of the 0° to +20° and 0° to −20° zones by excluding those regions where galactic features such as the North Polar Spur and the Cetus Arc influence the detection of weak sources. The apparent slope of the source counts at 408 MHz is -1.95, corrections for random errors in the measured flux densities and possible over-estimation of the flux densities of weaker sources would reduce the slope to ~ -1.85. For these sources, flux densities at 2,650 MHz are available, and their log N–log S relationship at this frequency is shown by the open circles in Fig. 1. Its slope of ~ -1.6 is significantly lower than the value at 408 MHz, the important result, however, is that the counts fall well below the counts from the 2,700 MHz survey, particularly at the higher flux densities. Most of the sources which are present in the 2,700 MHz survey, but missing from the Parkes catalogue, must have relatively flat spectra.

A similar result is apparent from a comparison of the results of the 2,700 MHz survey and the Cambridge surveys at 178 MHz. The composite curve due to Gower[3] for the source counts from the *3C* revised, *4C* and *5C* surveys is shown on the right-hand side of Fig. 1. Unfortunately, flux densities near 2,700 MHz are not available for these sources. We have therefore computed the expected source counts at 2,700 MHz by convolving Gower's results with the distribution of spectral indices given by Long *et al.*[4] for sources in the Cambridge catalogues with flux densities $\geqslant 5.0$ flux units. This is shown as a dashed line in Fig. 1. Relative to the observed counts at 2,700 MHz, the predicted counts show a marked deficiency for high flux densities and a slight excess at low flux densities.

We have, then, slopes for the log N–log S relationship down to a source density of 200 sr of -1.8 at 178 MHz, -1.85 ± 0.1 at 408 MHz, and -1.4 ± 0.1 at 2,700 MHz. Implicit in these differing slopes is a change in mean effective spectral index and/or the dispersion in spectral indices with flux density. For example, we can reproduce the 178 MHz counts from the 2,700 MHz counts by assuming a Gaussian distribution of spectral indices of standard deviation 0.17 (as found by Long *et al.* for *4C* catalogue sources stronger than 5 flux units (ref. 4)) with the mean effective spectral index given by

$$\bar{\alpha}_{2,700/178} = 0.56 - 0.179 \log S_{2,700} \qquad (1)$$

The 408 MHz counts may be reproduced from a similar expression.

Fig. 2 shows the 2,700 MHz survey sources on a diagram of $S_{2,700}$ against S_{178}. Here the 45° dashed lines are lines of constant effective spectral index over this frequency range. Sources which are not in the *4C* catalogue have been shown as having an upper limit of $S_{178} = 2.5$ flux units. Equation (1) is plotted as a dotted line, and detailed inspection indicates that it gives a reasonable representation of the trend in mean effective spectral index between 2,700 MHz and 178 MHz for these sources.

The transformation represented by (1), although effective, does not properly take into account the observed distribution of source spectra. Preliminary results from measurements at 468 MHz and 1,402 MHz with the Parkes interferometer indicate that as many as one-third of the 2,700 MHz survey sources which are not in the *4C* catalogue have inverted spectra. One example is Parkes 2,134+004, which has a flux density of 7·5 flux units at 2,700 MHz but for which the extrapolated flux density at 178 MHz is $\leqslant 0.2$ flux units—that is, below the limit of the fifth Cambridge catalogue.

In deriving the 2,700 MHz counts from the 178 MHz log N–log S curve, an apparent difficulty is encountered

The requisite changes with flux density in mean spectral index (for example, in accord with the relation reciprocal to (1)) and/or dispersion in spectral indices seem to be excluded by spectral measures of the 4*C* sources. Long *et al.*[4] have measured spectra in the frequency range 38 MHz to 1,410 MHz for 4*C* catalogue sources of $S_{178} \geqslant 5$ flux units, and Stewart and Long[5] have carried out the same measurements for a sample of 4*C* sources for which 2 flux units $\geqslant S_{178} \geqslant 5$ flux units. Both find the same mean spectral index of 0·75. Long *et al.* obtain a standard deviation for the spectral index distribution of 0·17, whereas Stewart and Long obtain the somewhat higher value of 0·25. Stewart and Long claim that the increase may be the result of experimental errors due to the lower flux densities involved. An examination of their Fig. 2, however, reveals a markedly different distribution of the spectral indices from that given in Fig. 1 of Long *et al.*, and we feel that the higher dispersion is likely to be real. A more important point, however, is that spectral indices in the range 38 to 1,410 MHz are not characteristic of effective spectral indices in the range 178 MHz to 2,700 MHz. A study of a large sample of sources in the Parkes catalogue has shown that the straight power law spectrum below 1,400 MHz exhibited by the majority of sources frequently does not continue to higher frequencies. For many radio galaxies the spectrum steepens, for many quasi-stellar objects it flattens, and not infrequently the slope reverses.

The reconciliation of the differing slopes for the log *N*–log *S* relationships at 178 and 2,700 MHz in terms of the spectral content of the surveys must therefore await complete investigation of the spectra of sources in both catalogues over this frequency range. It is evident from our preliminary investigations that the first requirement for this reconciliation—a difference in spectral content for the two catalogues—is indeed present.

The difference in spectral content is paralleled by a difference in identification content. The positions of all sources in the 2,700 MHz survey have been examined on the Palomar Sky Survey prints, and suggested identifications of optical counterparts for many of the sources have been made (unpublished results, J. V. Wall, J. K. Merkelijn and A. J. Shimmins). In Fig. 2, different symbols are used for identified galaxies, confirmed and possible quasi-stellar objects, and unidentified sources. It is apparent from this diagram that the identification content of the stronger 2,700 MHz sources is quite different from that of the stronger 178 MHz sources. For sources common to the 2,700 MHz and 178 MHz catalogues the ratio of galaxies to QSOs is 5 : 4. For sources not in the 4*C* catalogue the ratio is 1 : 10.

A further result from Fig. 2 is the clear distinction between the spectra of the radio galaxies and the QSOs which has previously been pointed out by two of us[6]. For sources with mean spectral index less than 0·4 the identifications are exclusively QSOs, between 0·4 and 0·6 the ratio of QSOs to galaxies is 2 : 1. Objects with spectral indices greater than 0·8 are almost exclusively galaxies. It seems that the unidentified sources lie in the region of the diagram occupied primarily by galaxies, which substantiates the argument[6] that the majority of unidentified sources are galaxies beyond the Palomar Sky Survey plate limit.

The question naturally arises as to which log *N*–log *S* slope is to be used in cosmological discussions. It has often been suggested that the evolutionary sequence for radio sources is such that the spectra steepen with age. On this basis, the more distant sources should have flatter spectra, and high frequency surveys with a selection bias in favour of flat spectrum objects might be more likely to reveal evolutionary effects. Another point in favour of high frequency source counts is that the flux density at a high frequency is more representative of a bolometric magnitude or integrated power than that at a low frequency. It is now known that there is a very large range in the form of radio source spectra, and, consequently, source counts in terms of flux density may not be valid substitutes for counts in terms of source power. Furthermore, the same source selection effects that produce the log *N*–log *S* slope at a particular frequency will also influence the identification content and the deductions from it. For example, from the quasi-stellar objects in the revised 3*C* catalogue, Schmidt[7] finds that the space density of QSOs at $z = 1$ is approximately a hundred times that of their local space density. A similar variation with epoch of the luminosity of one class of radio source is required by Longair's investigation[8] of the revised 3*C* sources. It has been shown here that the ratio of different types of radio sources in the 2,700 MHz survey departs radically from that of the revised 3*C* catalogue. It will be of great interest to see whether Schmidt's result for the 3*C* QSOs persists in the present sample when their red-shifts become available.

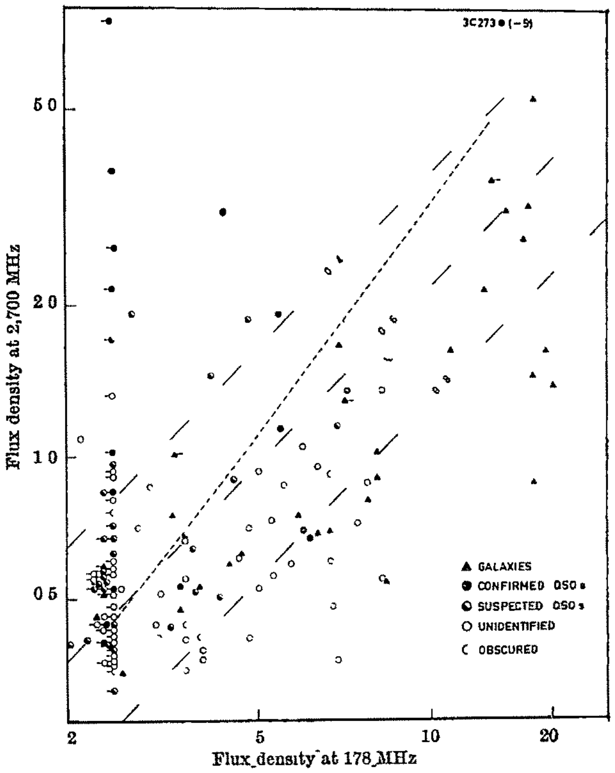

Fig. 2. The flux density at 2,700 MHz against the flux density at 178 MHz for sources from the 2,700 MHz survey of 0·34 sr. Different symbols indicate the identification class. 45° lines are lines of constant spectral index and the dotted line represents $\bar{\alpha}_{2\,700/178} = 0{\cdot}56 - 0{\cdot}197 \log S_{2,700}$. Sources not in the 4*C* catalogue are indicated as if they had an upper limit of 2·5 flux units at 178 MHz. Galaxies which are probably resolved in the 4*C* observations are indicated with the 178 MHz flux as a lower limit.

Finally, in view of the doubts raised on the interpretation of the slopes of the number–flux density relationships for the radio sources, their value as evidence against the steady state cosmology may be questioned.

We thank Miss J. K. Merkelijn for her assistance with the observations. One of us (J. V. W.) is grateful to the Australian National University for a research scholarship.

Purification of Antilymphocytic Antibody

by

M. F. A. WOODRUFF

Department of Surgical Science,
University of Edinburgh
and
MRC Research Group on Clinical and
Experimental Problems of Transplantation

By elution from human lymphocytes it has been possible to obtain antilymphocytic antibody of much greater purity than before

NEARLY all the antilymphocytic activity of horse-anti-human antilymphocytic serum (ALS) prepared by chronic immunization is concentrated in the IgG fraction but, as reported previously[1], in our preparations of antilymphocytic IgG (ALS IgG) only a small proportion (usually less than 1 per cent) of the molecules are effectively antilymphocytic. In the experiments reported here, antilymphocytic antibody of much greater purity has been prepared by elution from human lymphocytes previously incubated *in vitro* with either ALG or crude ALS.

Several methods of elution, including exposure for various times to buffered solutions of differing *p*H at 37° C and 56° C, and also to high concentrations of urea, were investigated in preliminary trials, and it seemed that the most promising method was exposure for about 20 min to acid media in the *p*H range 2·5 to 4·0.

In the first of three experiments, 250 million human peripheral blood lymphocytes, prepared as described before[2], were incubated for 1·5 h at 37° C in 25 ml of medium (tissue culture medium 199 with 20 per cent autologous inactivated plasma) to which was added 4 ml of a solution containing 35 mg of ALS IgG which had been labelled with iodine-131 by the method of Hunter and Greenwood[3]. The cells were spun down, washed once with McIlvain citric acid–phosphate buffer at *p*H 7·2, resuspended, distributed equally between four counting tubes, spun down again and, after the supernatants had been separated, counted for iodine-131 in a well-type scintillation spectrometer (Nuclear Enterprises 'Gammamatic'). The sum of the four cell counts was 2,432 c.p.s. and a sample of the ALS IgG counted at the same time yielded a count of 14,500 c.p.s./mg. If all the IgG molecules were labelled the mean number of molecules taken up per cell was thus

$$\frac{2{,}432\ N}{14{,}500\ 10^3\ 250\ 10^6\ m} = 2\cdot51 \text{ million}$$

where N is Avogadro's number $\simeq$ $6\ 10^{23}$ and m is the molecular weight of IgG $\simeq$ 160,000.

The cells in each tube were then resuspended in 3 ml of eluting medium, consisting of McIlvain citric acid–phosphate buffer at *p*H 2·5, 3, 3·5 and 3 in tubes 1–4, respectively, and transferred to miniature (10 ml) Erlenmeyer flasks. Flasks 1–3 were placed on a mechanical shaker in a water bath at 37° C, flask 4 was placed on a similar shaker in a water bath at 56° C. After 20 min the suspensions were transferred to tubes and centrifuged; cells and eluates were then separated and counted for iodine-131, after which the eluates were brought to *p*H 7·2 by the addition of 1 N sodium hydroxide and dialysed overnight at 4° C against medium 199. The volume of each eluate was then made up to 4 ml with medium 199.

The proportion of adsorbed protein eluted in each tube and the protein content of each eluate were calculated from the iodine-131 counts. The agglutinin and cytotoxic titres^{-1} of a solution of the original labelled ALS IgG containing 0·875 g/100 ml were determined in the usual way and found to be 1,024 and 512, respectively. The titres^{-1} of each eluate were similarly determined (Table 1). The lymphocyte binding and lymphocyte stimulating activity of the eluted antibody was investigated by adding 1·4 ml of each eluate to human lymphocyte cultures[1,2] containing tritiated uridine and measuring the amount of iodine-131 and tritium taken up by the cells. Control cultures were set up, some containing various amounts of the original labelled ALS IgG, others without the addition of any antilymphocytic antibody. After 24 h the cells were prepared for liquid scintillation counting and counted with a Packard 'Tricarb' scintillometer using two channels, one adjusted for iodine-131 and the other for tritium. The iodine-131 and tritium activity in each culture was then calculated as described before[1], due allowance being made for the influence of iodine-131 on the count in the tritium channel. All cultures were in duplicate and the ratio of the mean tritium activity in a pair of cultures with added ALG or eluate to the mean tritium activity of the controls is referred to hereafter as the mean relative tritium activity. The control cultures were used to establish dose response curves (Fig. 1) relating the mean number of IgG molecules taken up per cell and the mean relative tritium activity to the amount of ^{131}I-labelled ALS IgG in the culture. The measured uptake of IgG per cell and mean relative tritium activity in the cultures containing eluted antibody are set out in Table 1. The amounts (E_I and E_H) of the original labelled ALS IgG which would produce the observed values of iodine-131 uptake and mean relative tritium activity have been read off from Fig. 1 and are shown in the same table. This table also shows values, calculated as described later, for the proportions of agglutinating, cytotoxic, lymphocyte binding and

Table 1 ELUTION OF ANTILYMPHOCYTIC ANTIBODY FROM LYMPHOCYTES EXPOSED TO ^{131}I-LABELLED ALS IgG

* Based on observations with cultures containing 1·4 ml eluate obtained from 3 g of labelled ALS IgG.

E_I and E_H denote the amounts of the original labelled ALS IgG which, from Fig. 1, would produce the observed uptake of iodine-131 and the observed mean relative tritium activity, respectively.

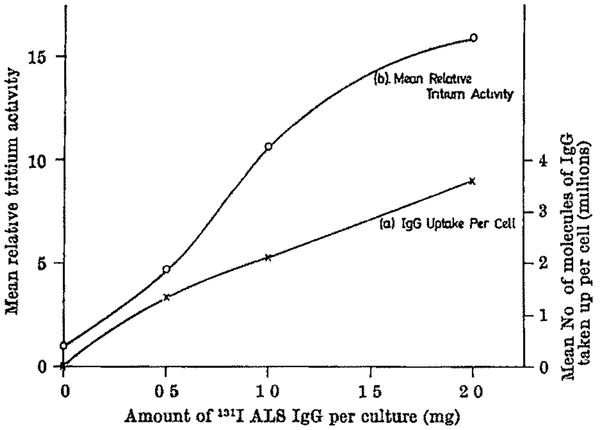

Fig 1 Dose response curves for human lymphocyte cultures containing tritiated uridine and ^{131}I-labelled ALS IgG relating (*a*) the number of IgG molecules taken up per cell and (*b*) the relative tritium activity to the amount of labelled IgG per culture

lymphocyte stimulating activity recovered by the combined adsorption–elution procedures, and the relative activity of each eluate as compared with the original labelled ALS IgG in respect of the same four properties

The proportions of agglutinating and cytotoxic activity recovered are clearly given by $\frac{T_A'}{T_A}$ V' and $\frac{T_C'}{T_C}.V'$, respectively, and the corresponding relative activities by $\frac{T_A'}{T_A}.\frac{P}{P'}$ and $\frac{T_C'}{T_C}$ $\frac{P}{P'}$, where T_A', T_C', P' denote, respectively, the reciprocal agglutinin and cytotoxic titres and the protein concentration of the eluate, T_A, T_C, P the reciprocal agglutinin and cytotoxic titres and the protein concentration of the original labelled ALS IgG, V' the volume of eluate per unit volume of the original labelled ALS IgG solution The proportions of lymphocyte binding and lymphocyte stimulating activity recovered might be defined, by analogy, as $\frac{E_I}{G}$ and $\frac{E_H}{G}$, respectively, and the corresponding relative activities by $\frac{E_I}{G}$ $\frac{P}{P'}$ and $\frac{E_H}{G}$ $\frac{P}{P'}$, where E_I and E_H have the meanings already ascribed, and G ($=3$ mg) denotes the amount of original labelled ALS IgG from which the eluted antibody in one culture was obtained These definitions must, however, be regarded as purely operational because, as will be seen later, different values are obtained if the conditions of assay are changed by altering the amount of eluted protein per culture

It will be seen that, of the procedures tried, elution at 37° C in a medium of *p*H 3 0 or 3 5 gave the biggest yield of antibody as judged by agglutinating activity, lymphocyte binding activity and lymphocyte stimulating activity At *p*H 2 5 (37° C) more protein (strictly speaking, more label) was eluted, but this gain did not compensate for the loss of activity, at 56° C (*p*H 3 0) the amount of protein eluted was the same as at 37° C (*p*H 3 0) and its capacity to bind to lymphocytes was relatively high, but stimulating activity was completely lost

The object of the second experiment was to investigate the possibility of obtaining purified antilymphocytic antibody by using crude ALS instead of ALS IgG as the starting point for the adsorption–elution procedure The ALS was obtained from the same chronically immunized horse which provided the serum from which the ALS IgG used in the first experiment was prepared It was inactivated by heating to 56° C for 30 min and then absorbed with one-third its volume of packed human AB red cell stroma, as a result of which the haemagglutinin titre^{-1} was reduced from 2,048 to 8. The agglutinin and cytotoxin titres^{-1} of the serum were both 1,024, and the IgG content was approximately 1 g/100 ml

Two hundred million human peripheral blood lymphocytes suspended in 20 ml medium 199 were mixed with 20 ml of ALS and incubated for 1 5 h at 37° C in a 500 ml Erlenmeyer flask, with gentle shaking for 2 min every 10 min The suspension was then distributed equally between four tubes, after which the cells were spun down, washed once and resuspended in 3 ml of eluting medium consisting of McIlvain citric acid–phosphate buffer of *p*H 2 5, 3 0, 3 5 and 4 0 in tubes 1–4, respectively Elution was carried out for 20 min in miniature Erlenmeyer flasks as in the first experiment, the only difference being that all the flasks were kept at 37° C After separation of the cells the eluates were brought to *p*H 7 2 by the addition of 1 N sodium hydroxide and dialysed overnight at 4° C against medium 199. The volume of each eluate was then made up to 5 ml with medium 199

Lymphocyte cultures containing tritiated uridine were set up in duplicate to provide dose response curves relating lymphocyte stimulating activity (as judged by uridine uptake) to the amount of ALS or eluate added to the culture, using doses of 0 05, 0 1 and 0 2 ml. of ALS, and 0 3, 0 6 and 1 2 ml of eluate The lymphocyte agglutinin and cytotoxin titres^{-1} of each eluate were determined in the usual way, and the proportions of agglutinating and cytotoxic activity recovered by the combined adsorption–elution procedure were calculated as in the first experiment Values have also been calculated for $\frac{E_H}{G}$, which was defined earlier as the proportion of lymphocyte stimulating activity recovered, as already mentioned, however, the values obtained for each eluate depend on the amount added to each culture The results are summarized in Fig 2 and in Table 2, which shows for each eluate the proportions of agglutinating and cytotoxic activity recovered, and the values of $\frac{E_H}{G}$ at two doses of eluate per culture, namely, 1 2 and 0 6 ml , corresponding to the amounts obtained from quantities of ALS containing 12 mg and 6 mg of IgG, respectively

Once again, of the procedures tried, elution at 37° C in a medium of *p*H 3 0 or 3 5 gave the biggest yield of antibody as judged by agglutinating and stimulating activity As in the first experiment, very little cytotoxic activity was recovered in any of the eluates

A third experiment was performed to determine whether the recovery of antibody from ALS at a *p*H between 3 0 and 3 5 might be improved (*a*) by carrying out the elution in two stages and (*b*) by adding human serum protein to the eluate before dialysis to protect against denaturation Three hundred and twenty million human peripheral blood lymphocytes suspended in 30 ml of medium 199 were mixed with 32 ml of ALS and incubated

Table 2 ELUTION OF ANTILYMPHOCYTIC ANTIBODY AT VARIOUS *p*H FROM LYMPHOCYTES EXPOSED TO ALS

No	Eluate		Agglutinating activity		Cytotoxic activity		E_H/G (Proportion of lymphocyte stimulating activity recovered)	
	Conditions of elution *p*H	°C	Titre^{-1}	Proportion recovered (%)	Titre^{-1}	Proportion recovered (%)	Values obtained in tests with 1 2 ml of eluate per culture	Values obtained in tests with 0 6 ml of eluate per culture
1	2 5	37	32	3	4	1	4 0	1 7
2	3 0	37	128	12	4	1	25 0	4 2
3	3 5	37	128	12	8	2	26 7	3 7
4	4 0	37	4	<1	4	1	2 0	2 3

as before for 1·5 h at 37° C. The suspension was then transferred to a large (100 ml.) tube and centrifuged The supernatant was separated and stored overnight at 4° C The cells were washed once, resuspended in 5 ml of McIlvain citric acid–phosphate buffer, *p*H 3·3, and transferred to a small Erlenmeyer flask which was shaken in a water bath at 37° C After 10 min, the suspension was transferred to a small tube and centrifuged The eluate was recovered, brought to a *p*H of approximately 6·0 by the addition of an equal volume of 0·2 M disodium phosphate and cooled to just above 0° C The cells were resuspended in 5 ml. of buffer at *p*H 3·3, and transferred back to the small Erlenmeyer flask in the water bath at 37° C After a further 15 min the eluate was again separated, brought to *p*H 6·0 and cooled, and the cells were resuspended in 5 ml of fresh buffer The two lots of eluate were thoroughly mixed Half of the composite eluate was mixed with 4 ml of inactivated human plasma and then simultaneously concentrated by ultrafiltration and dialysed overnight at 4° C against phosphate buffer, *p*H 7·2, to yield preparation *A*, the other half was similarly dialysed without previous addition of plasma to yield preparation *B* Both preparations were thus reduced in volume to slightly less than 4 ml and later made up to 4·0 ml by the addition of phosphate buffer, so that the volume of each preparation was one-quarter the volume of ALS from which it was derived, and preparation *A* was approximately equivalent to human plasma in respect to the content of human protein The nitrogen content of each sample of preparation *B* was determined by a micro-Kjeldahl procedure and found to be 52·6 µg/ml, corresponding to approximately 33 mg of protein/100 ml The lymphocyte agglutinating, cytotoxic and stimulating activity of these preparations, and also of the ALS before and after absorption with human lymphocytes, were measured in the usual way and the results are shown in Table 3 and Fig 3. It would seem that the two stage elution procedure has improved the yield of agglutinating antibody. This is most apparent in eluate *A* containing human plasma, but the difference between the two eluates depends on one tube in the agglutination test and cannot be regarded as significant Little or no cytotoxic activity was demonstrated in either eluate The uridine uptake curves are virtually identical for both, and are similar in form to those obtained with eluates 2 and 3 of the previous experiment, the recovery of stimulating activity also appears to be much the same as before if allowance is made for the four-fold concentration of eluates *A* and *B*.

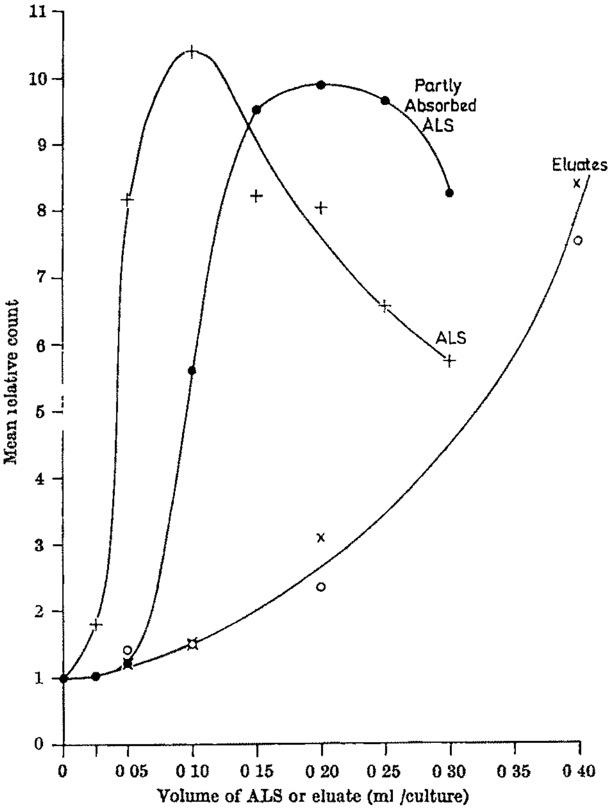

Fig 3 Dose response curves for human lymphocyte cultures containing tritiated uridine and either unabsorbed ALS, ALS partly absorbed with human lymphocytes or eluted antibody The curves relate the mean relative tritium count to the amount of ALS or eluate per culture See text (third experiment) for conditions of elution Because the points (× for eluate *A* and ○ for eluate *B*) for the two eluates fall so closely together, a single curve has been drawn to fit them

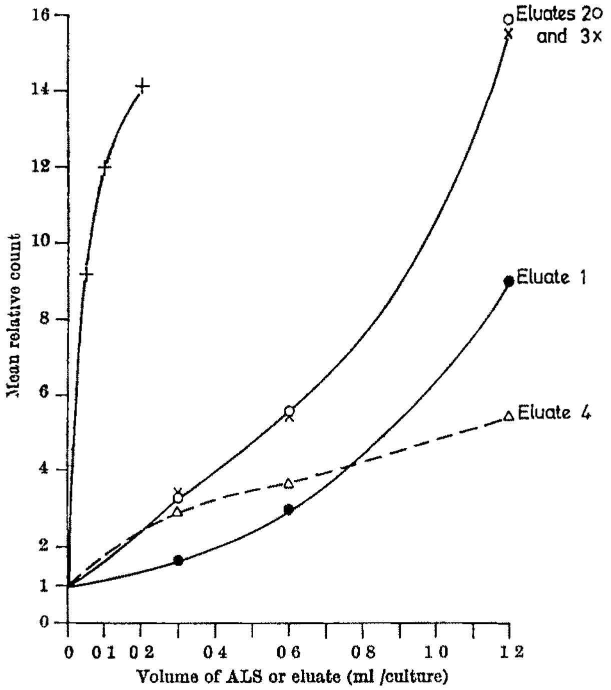

Fig 2 Dose response curves for human lymphocyte cultures containing tritiated uridine and either ALS or eluted antibody relating the mean relative tritium count to the amount of ALS or eluate per culture See text (second experiment) for conditions of elution Because the points for eluates 2 and 3 fall so closely together, a single curve has been drawn to fit them

There are two features of the results which would seem to merit special comment First, it is noteworthy that preparations have been obtained which are extraordinarily potent in respect of lymphocyte agglutinating and stimulating activity but which have little or no demonstrable cytotoxic activity In these respects, the purified antibody resembles[2] the divalent antibody fragment F(ab′)$_2$ which is obtained when the complement binding part of the IgG molecule is destroyed by digestion with pepsin It seemed possible that in the present elution experiments exposure to acid might have caused the loss of cytotoxic activity either by selectively destroying a subpopulation of antibody molecules responsible for such activity or by damaging the complement binding sites of IgG molecules in general

To test this a solution of ALS IgG was acidified to *p*H 3

Table 3 ELUTION OF ANTILYMPHOCYTIC ANTIBODY (TWO STAGE PROCEDURE) AT *p*H 3·3

Preparation	Protein content: Horse IgG (mg/100 ml.)	Protein content: Human plasma proteins	Agglutinating activity: Titre^{-1}	Agglutinating activity: Proportion recovered (%)	Cytotoxic titre^{-1}
Original ALS	Approx 1,000	Nil	1,024		1,024
Absorbed ALS	Not measured	Nil	512		512
Eluate *A*	33	As normal human plasma	2,048	50	< 4
Eluate *B*	33*	Nil	1,024	25	< 4

* The N content by micro-Kjeldahl was 52·6 µg./ml

with 0.1 M citric acid and incubated at 37° C for 20 min. The solution was then brought to pH 6 by the addition of 0.2 M disodium hydrogen phosphate and dialysed overnight against phosphate buffer, pH 7.2, at 4° C. During the course of the dialysis the volume was reduced to that of the original ALS IgG solution by ultrafiltration. This "acid-treated IgG" was found to possess the same lymphocyte agglutinating activity as the IgG from which it was prepared ($\text{titre}^{-1} = 4{,}096$ in each case), but the cytotoxic titre^{-1} was reduced by the treatment from 2,048 to 64. The lymphocyte stimulating activity as judged by uridine uptake in lymphocyte cultures devoid of complement was only slightly reduced by the treatment (Fig. 4*a* and *b*); on the other hand, in cultures containing complement[2] the treated IgG caused greater stimulation than the untreated IgG. It therefore seems clear that cytotoxic activity is selectively reduced, as compared with agglutinating or lymphocyte stimulating activity, by exposure to pH 3 at 37° C. Loss of cytotoxic activity thus seems inevitable with the method of elution used in the present experiments.

Because, as already reported[4], the immunosuppressive capacity of $F(ab')_2$ is small in comparison with that of the ALS IgG from which it is prepared, it would be interesting to measure the immunosuppressive capacity of acid-treated or eluted antibody. This is being undertaken in rats with purified antibody prepared from horse-anti-rat ALS.

Second, the dose response curves relating uridine uptake by lymphocytes in culture to the amount of antibody in the medium given by antibody eluted at optimal pH are markedly different in form from those obtained with either crude ALS or ALS IgG. Thus at a level of uridine uptake which is maximal or near-maximal for cells exposed to ALS or ALS IgG, the slope of the curve for eluted antibody is both steep and increasing.

Some light on possible reasons for this difference is provided by the data obtained with ^{131}I-labelled antibody. In previous observations[1] with human lymphocyte cultures containing tritiated uridine and ^{131}I-labelled ALS IgG it was found that there was an approximately linear relationship between the relative tritium activity and the number of IgG molecules taken up per cell, in so far as there was any departure from linearity a sigmoid curve appeared to give the best fit. It will be seen from Fig. 5, plotted from the data presented more fully in Fig. 1, that in the first experiment of those now reported there is the same sort of relationship between tritium activity and IgG uptake in cultures treated with unpurified ALS IgG, that is, a straight line fits the data approximately but a sigmoid curve is better. The effect of the eluates was observed at only one dose level for each, it will be seen, however, that the points for the active eluates (2 and 3) lie well to the left of the straight line fitted to the points obtained with unpurified IgG and *a fortiori* to the left of the sigmoid curve. While it would be unwise to seem to draw far-reaching conclusions from these two observations, they do at least suggest that it may be necessary to make a further revision of our hypothesis concerning the heterogeneity of antilymphocytic IgG molecules. We began by postulating that ALS IgG contains only two classes of molecule, namely, antilymphocytic molecules which bind to and stimulate lymphocytes and non-antilymphocytic molecules which neither bind nor stimulate. It became apparent that this was an over-simplification and that antilymphocytic IgG molecules formed a heterogeneous population, the previous experimental findings could, however, be accounted for by postulating heterogeneity in respect of avidity only and retaining the assumption that all IgG molecules which become attached to a lymphocyte exert an equal stimulating effect. We have now at least a suggestion that individual antilymphocytic IgG molecules may differ also in respect of their stimulating capacity.

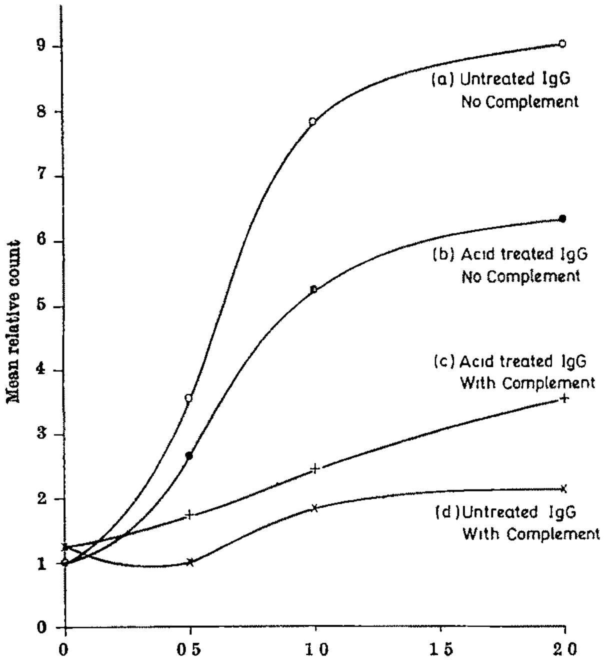

Fig. 4. Dose response curves for human lymphocyte cultures containing either untreated ALS IgG (*a*, *d*) or ALS IgG which had been exposed to pH 3.0 for 20 min at 37° C (*b*, *c*). Curves *a* and *b* relate to cultures set up in the usual way in a medium consisting of medium 199 with 20 per cent heat-inactivated autologous plasma. Curves *c* and *d* relate to cultures containing 20 per cent unheated autologous plasma. This was added after the ALS IgG.

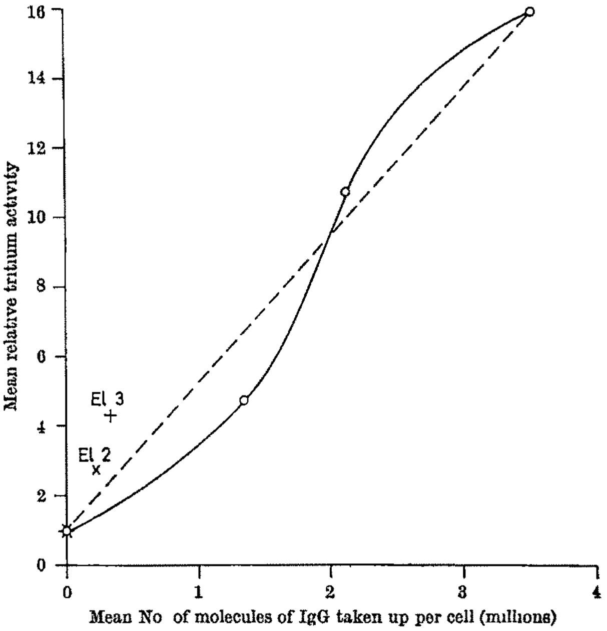

Fig. 5. Relationship between mean relative tritium activity and the number of molecules of ^{131}I-labelled antibody taken up per cell. The points connected by the sigmoid curve are based on data presented more fully in Fig. 1 and relate to cultures containing unpurified ALS IgG. The isolated points marked *El* 2 and *El* 3 relate to cultures containing eluted labelled antibody (eluates 2 and 3 of Table 1).

I thank Dr Keith James for helpful suggestions and for preparing and labelling the IgG used in the first experiment. I also thank W. McBride for performing the micro-Kjeldahl determinations and Mr George Brooks for technical assistance.

New Controlling Element in the *Lac* Operon of *E. coli*

by
KARIN IPPEN*

The *lac* promoter maps between the repressor *i* gene and the operator *o* gene, so that the operator gene is probably transcribed.

THE genetic elements (*lac*) determining lactose metabolism in *E. coli* map very close together in a small region of the chromosome (Fig. 1)[1]. Three structural genes, *z* (for β-galactosidase), *y* (for galactoside permease) and *a* (for thiogalactoside transacetylase), are regulated by the repressor product of the *i* gene. In the absence of β-galactoside inducers of the system, the repressor interacts with the *lac* operator (*o*) to prevent synthesis of the three proteins. Jacob and Monod have suggested that repression involves an inhibition of transcription of *lac* operon DNA into a messenger-RNA (*m*RNA) copy[1]. This model for regulation has recently received strong support from the experiments of Gilbert and Muller-Hill, who have isolated the repressor protein and have found that it binds specifically to *lac* operator double-stranded DNA[2]. Thus it seems likely that this repressor–operator complex prevents transcription of the *lac* operon.

There is genetic evidence indicating that it is not the operator itself which serves as a transcription initiation site. Whereas one would expect mutations in an initiation site to alter the potential for operon expression, operator-constitutive (o^c) mutations, including some well characterized deletions (unpublished results of Davies and Jacob), do not affect the rate at which the operon can be expressed[3]. Such an initiation site must therefore lie outside the operator, either between *i* and *o* or between *o* and *z*. Jacob, Ullman and Monod[3] have proposed that such a site, the promoter (*p*), maps between *o* and *z*.

We have reported the isolation and characterization of mutants which have all the properties of mutants in an initiation site of the *lac* operon[4]. These mutants, which reduce the maximum rate of *lac* operon expression, do not alter either the operator or the *i* gene. On the basis of genetic mapping, we had concluded that these mutants altered a site between *o* and *z*, possibly identical to the promoter. This conclusion was based on the use of certain i-o^c mutants thought to be deletions extending from the operator into or beyond the *i* gene[3]. Davies and Jacob have now shown, however, that these mutants are not overlapping deletions (unpublished results). In fact, it now seems likely that most or all of them behave as either negatively complementing i^- mutations (personal communication from J. Davies and W. Gilbert) or as double mutants (unpublished results). The former class would be mutations in the *i* gene, which produce a defective subunit of the repressor, impairing the normal function of wild-type repressor sub-units. The findings of Davies and Jacob have led us to re-examine the mapping of our mutants.

We present here conclusive evidence that the genetic site altered in our mutant maps between *i* and *o*. This evidence thus identifies a new controlling element determining the expression of the *lac* operon. We propose that it is in this region that the initiation of transcription takes place. Because, in the original formulation of the promoter concept, it was considered most likely that the site defined as promoter was an initiation point for *m*RNA transcription[3], we prefer to retain the term promoter to describe this new region (Jacob and Monod, personal communication, agree with this use of the term promoter). It now seems probable that, in fact, the region between *o* and *z* corresponds only to an initiation site for translation.

We have characterized four ultraviolet-induced mutants which co-ordinately reduce the rate of expression of the *z*, *y* and *a* genes. Some of their properties are described in Table 1. Three of these, although independently isolated, are almost identical in their characteristics, and at least two, *L*8 and *L*37, do not recombine with each other (unpublished results of J. Beckwith). *L*8 and *L*37 do, however, seem to be point mutants[9]. The lesion in the fourth mutant, *L*1, confers an additional property on the strain, and, although the operator in *L*1 is normal, the activity of its *i* gene is reduced.

Table 1

	Induced levels of *lac* enzymes as percentage of wild-type	Regulation	*cis*-Dominant
*L*1	2	Partly constitutive	Yes
*L*8, *L*37	6	Normally inducible	Yes
*L*29	4	Normally inducible	Yes

Three of these mutants, *L*1, *L*8 and *L*37, have been described before[4]. The fourth, *L*29, was isolated as one of two lac^- mutants found after ultraviolet mutagenesis of a lac^+ strain. The *o* and *i* characters of *L*1 were determined in diploid studies.

These mutations are *cis*-dominant in that they only reduce the rate of expression of the operon on the same chromosome and these effects are not relieved by the introduction of a second *lac* region into the cell[4]. An explanation for the properties of these mutants is that they have altered a site essential for the initiation of either transcription or translation of the operon. The result is a reduced efficiency of reading. In order to determine conclusively the position of the mutants relative to the operator and the *i* and *z* genes, we have employed a deletion analysis of this region. To avoid confusion we shall call these promoter mutants.

We have described a genetic system in which it is possible to isolate deletions removing the distal end (*a*

† On leave from MRC Microbial Genetics Research Unit, London.

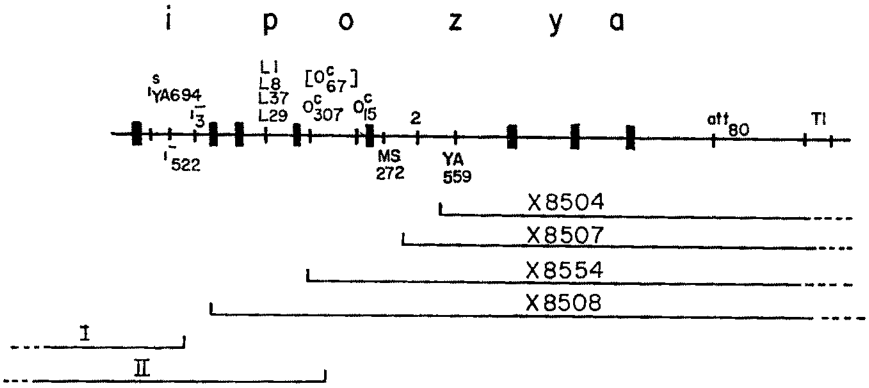

Fig 1 The *lac* operon transposed (in $\varphi 80dlac$) to the $\varphi 80$ site on the bacterial chromosome The $T1^R$ mutations were selected as before[7] All *i* gene and o^c mutations were isolated by Jacob, Monod and co-workers Lac^-_{MS272} is an extremely polar mutant isolated by Malamy[8] Lac^-_2 and lac^-_{YA559} have been described before[9] The orders of *i* and *o* mutations which are not established by deletion mapping have been determined by Davies and Jacob (results in preparation)

end) of the operon and extending varying distances toward and past the operator (Fig 1)[5] These deletions are isolated in a strain in which a $\varphi 80dlac$ transducing phage is integrated in the chromosome near the locus ($T1$) determining sensitivity to the bacteriophages $T1$ and $\varphi 80$ In the strain described in Fig 1, the *lac* region is inverted from its normal orientation on the chromosome so that the *i* gene is furthest from the $T1$ locus By selecting $T1^R$ mutants of such a strain, it is possible to isolate deletions extending from the $T1$ locus or beyond into the defective prophage[5,6] These deletions are presumed to include all the genetic material between the $T1$ locus and the determined deletion end, for they remove all point mutant sites in the *y* gene and in the *z* gene as indicated

The deletions isolated in this way, which we have used in our mapping studies, are described in Fig 1 Table 2 shows the frequency of recombination of these deletions with mutants affecting various components of the *lac* operon and the *i* gene These include an i^s mutation, two i^- mutants, four promoter mutants, three o^c mutants and three z^- mutants One of the mutants, o^c_{307}, was shown by Davies and Jacob (unpublished results) to map the furthest to the left of any known o^c mutant In most cases, the deletion strains were infected with an F' factor (*F-lac-pro*) carrying the mutation to be mapped Cultures of these partial diploids were then screened for recombinants. It should be noted therefore that the frequencies reported in Table 2 do not correspond to recombination frequencies measured in the standard way

The crucial deletion for determining the position of the promoter mutants relative to the operator is $X8554$ Two promoter mutants, $L8$ and $L37$, give frequencies of 0 065–0 086 per cent recombinants with this deletion In contrast, no recombinants have been detected between this deletion and any of the o^c mutants as indicated in Table 2 Either this deletion covers the entire operator region, or else its terminus lies very close to the end of the operator nearest the *i* gene In general, the other frequencies presented in Table 2 are entirely consistent with the order of mutations as determined by their ability to recombine with a series of other point mutations and deletions The map order is also in complete agreement with respect to the order of *i* and *o* mutations determined by Davies and Jacob (unpublished results) Furthermore, the results unambiguously show that the position of all four promoter mutations is between *i* and *o*

We have presented genetic evidence showing that mutants affecting the maximum level of *lac* operon expression map in the region between *i* and *o* The properties of these mutants can be accounted for by two different general explanations (1) These mutants define a site necessary for expression of the *lac* operon, which can be altered by mutation to reduce operon activity. (2) The mutants map outside all controlling sites for the operon, but in some undefined way affect operon expression negatively Although it is very difficult to conceive of any simple mechanisms for the second explanation, it is, of course, imperative to show directly that these mutants define an essential site

There is some evidence indicating that the region between *i* and *o* is essential to operon expression It is possible to isolate *lac*-constitutive mutations which are caused by deletions (Table 2) cutting into either the *i* gene (class I) or the *o* region (class II) from a point outside the *i* end of the *lac* region[5] In such a system we have isolated a large number of i^- lac^+ deletions In addition,

Table 2 PERCENTAGE OF RECOMBINANTS AMONG TOTAL COLONIES

Deletion Mutant	$X8504$	$X8507$	$X8554$	$X8508$
z^-_{YA559}	0	0	0	0
z^-_2	+	0	0	0
z^-_{MS272}	+	+	0	0
o^c_{15}	0 26	0 037	< 0 001	n t
o^c_{307}	n t	n t	< 0 001	n t
o^c_{67}	n t	n t	< 0 002	n t
$L1$, $L29$	+	+	+	0
$L8$	–	+	0 065	0
$L37$	0 79	0 34	0 086	0
i^-_3	n t	n t	0 19	0 069
i^-_{522}	n t	n t	0 16	0 094
i^s_{YA694}	+	+	0 24	+

The deletions are isolated in a strain carrying the $\varphi 80lac$ as described in the text and also carrying a *lac-proA,B* deletion To estimate the percentage of recombinants we constructed strains in which the mutant to be mapped against the deletion was carried on an *F-lac-proA,B*$^+$ episome With the dominant i^- mutation (i^-_{522}) and the o^c mutants, aliquots of a culture of a strain partially diploid in this way, for the *lac* region, were spread on to minimal medium (M63) containing glucose as carbon source, 5-bromo-4-chloro-indoxyl-β-D-galactoside (Xg, 0 004 per cent) and 0 004 M sodium citrate, necessary for the growth of $T1^R$ strains on this medium Because Xg is not an inducer[6], the constitutive diploid strains were blue and any i^+o^+ recombinants were white on these plates White colonies appearing on such medium were purified and assayed for β-galactosidase to ensure that they carried a wild-type *lac* region The same method was used to map the i^- deletion $X8508$ against i^-_3 The frequency of the *i* gene mutations with $X8554$ is actually the frequency of homogenotization of the i^+ or i^- allele To map the promoter mutants, $L8$ and $L37$, cultures of partially diploid strains were spread on *lac*-EMB plates and pure lac^+ (wild-type) colonies were picked and verified by assay The percentage of recombinants is based on samples from many independent diploid cultures, the frequencies are not seriously biased by "jackpots" caused by recombination events occurring early in the growth of the culture Some mutations (in F' donors) were mapped by crossing against the F^- *lac* S^r strains and selecting lac^+S^r recombinants (spot tests) Positive results are indicated as + and negative as 0 These spot tests detect recombinants at a much higher efficiency than the scoring techniques described here Some combinations were not tested (n t) we have isolated one deletion of class II. This deletion removes the *i* gene and the promoter region, but leaves part of the operator intact. As expected, the expression of the operon is impaired by the deletion of the promoter region. The properties of this strain will be described elsewhere (unpublished results of J. H. Miller, J. R. Beckwith and E. R. Signer). In addition to confirming the mapping results described here, the properties of this deletion also point to the importance of the promoter region in the expression of the *lac* operon. Thus it seems most likely that the mutants, *L*1, *L*8, *L*37 and *L*29, do lie in an essential region (the promoter) determining the initiation of operon expression.

The evidence pointing to a new site essential to *lac* operon expression which maps between *i* and *o* provides strong indication that the transcription process is initiated before the operator region. This conclusion does not exclude the possibility that the initiation of operon translation also occurs in this region. If protein synthesis does begin before *o*, however, then the operator should be translated; there is no evidence to support this prediction. We therefore favour the view that there are two sites essential to the expression of the *lac* operon. One would be the promoter, lying between *i* and *o*, which is the site of initiation of *m*RNA synthesis. Initiation of translation may then take place at a second site in the *o*–*z* boundary region, defined by Jacob, Ullman and Monod[3].

With this picture of the organization of the controlling sites of the *lac* operon, it is possible to visualize a fairly straightforward mechanism for the expression and regulation of operon activity. According to this scheme, the promoter region serves as the initiation point for transcription, possibly by acting as a binding site for RNA polymerase. Promoter mutants would reduce the site's affinity for the polymerase. While it is possible that the repressor hinders binding of RNA polymerase, the results presented here suggest a very simple alternative. In binding to the operator, the repressor could directly block the progress of the RNA polymerase into the structural genes of the *lac* operon.

Lower Dentition of *Kenyapithecus africanus*

by
L. S. B. LEAKEY
National Centre for Prehistory and Palaeontology, Nairobi

A mandible of *Kenyapithecus africanus*, with many of the teeth preserved, has been found at Kathwanga, Rusinga Island, Kenya. Previously the lower dentition of this species was unknown—except by inference from the mandible fragments with the crowns of the teeth broken off. The age of this member of the Hominidae is early Miocene.

SINCE the report of the discovery of early Miocene Hominidae on Rusinga Island[1] detailed geological studies of the deposits on the island have been carried out by Mr John van Couvering.

While van Couvering was engaged on this work, his wife, Judy, assisted by Erastus Ndere, undertook palaeontological work with a view to obtaining additional material of the fossil reptiles and fishes that occur in the Rusinga deposits. During this work, however, they noticed some primate teeth, on the surface, at Kathwanga (Site 5 of Rusinga Island)[2]. Following this up, they located the anterior region of a mandible *in situ*. The surface specimens and the *in situ* fragment have now been fitted together. The result provides the first opportunity to study the nature of the lower dentition of *Kenyapithecus africanus*.

Site and Geological Age

The specimen which will be described has been catalogued as Rusinga 1967, No. 394, and is housed at the Centre for Prehistory and Palaeontology, Nairobi. It comes from the site which was recorded as *R*.5 (ref. 2) in 1932. This is at Kathwanga on the west side of the island. The geological horizon from which the mandible was obtained is a grey tuffaceous deposit which forms part of the Kathwanga series. This series is at present regarded as the youngest element of the fossiliferous deposits of the Lower Miocene sequence on Rusinga[3]. As a result of the new geological work which has been carried out by van Couvering it is hoped that further evidence for dating by potassium–argon methods will soon be available from specimens which he has collected. There will also be a much more detailed picture of the overall stratigraphic sequence of the deposits exposed on the island and the relative age of the strata, visible at different sites.

The description of the specimen is: Family, Hominidae; genus, *Kenyapithecus*, Leakey 1961; species, *africanus* (Le Gros Clark and Leakey, 1951). The detailed diagnosis was given in ref. 1.

The new specimen consists of the greater part of a well-preserved mandible with many of the teeth preserved. The whole of the symphyseal region is in perfect condition anteriorly, except for very slight damage to the alveolar margins of the incisor sockets. All the incisor teeth had been lost before fossilization and the sockets are completely filled with matrix. The left canine is intact, while the crown of the right canine has been broken off about halfway up its length. On the right side the corpus of the mandible is reasonably intact to a point just behind the third molar, but the whole of the ascending ramus is

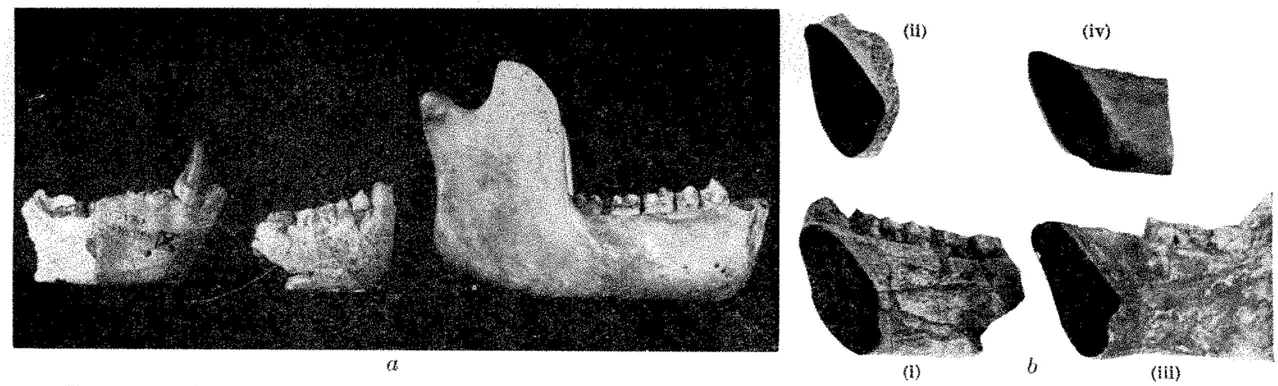

Fig. 1. *a*, Profile view of the new *Kenyapithecus africanus* mandible (centre) compared with *Proconsul major* (left) and gorilla (right). *b*, Cross-sections through the symphysis of the mandible of *Kenyapithecus africanus* (i), the earlier specimen *CMH* 142 (ii), *Proconsul nyanzae* (iii) and chimpanzee (iv).

missing as well as small parts of the inner wall of the corpus. On the left side, the corpus has broken off diagonally in a line starting just behind the second molar, at the alveolar margin, extending forwards to a point below the first molar. In addition to the loss of the incisors, the left fourth premolar, part of the left first molar and the left third molar are missing.

The morphology of the specimen compares very closely with that of the two mandibular fragments of *Kenyapithecus africanus*, from Rusinga Island, which were described before[1]. The chin region in the present specimen is rounded, as in the previously published specimens, and not triangular as in all examples of *Proconsul*. There is a slight depression on either side of the mid-line just below the alveolar margin. The sockets of the incisors lie in a straight line between the crowns of the canines—exactly as in the previously described specimens[1]. The corpus of the mandible is relatively high at the third premolar and narrows rapidly backwards towards the area of the third molars (Fig. 1*a*). In this respect, there is a measure of similarity with *Proconsul major*, but not with other species of *Proconsul*. The body of the corpus is not massive. At the fourth premolar where the height is 34 mm the bilateral thickness is only 13·5 mm; on the earlier specimen *CMH* 142 (ref. 1) the corresponding figures are 39·5 and 13 mm, while in *Proconsul major* they are 39 mm and 21 mm, and in a female specimen of *Proconsul nyanzae*, 32·25 mm and 16 mm.

The cross-section through the symphyseal region is similar to that already described[1] (Fig. 1*b*). This illustration is based on cutting through a plaster cast of the new mandible along the mid-line. From the incisural, lingual, alveolar margin the wall of the mandible, in the intercanine area, slopes rapidly downwards and slightly backwards, to well beyond the midway point of the total height and then forwards again. In *Proconsul* the initial slope is less steep and more backwards.

A noticeable feature of the morphology is the relatively great width between the canines, compared with any species of *Proconsul*. The measurement between the inner alveolar margins of the canines of the new *Kenyapithecus* specimen is 20·5 mm. In a *Proconsul nyanzae*, of comparable size, it is only 16·5 mm and even in the very much larger *Proconsul major* only 20 mm. In the specimen of *Kenyapithecus africanus* from Rusinga[1] the corresponding figure was 17·5 mm.

Linked with this large inter-canine width is the marked backward divergence of the molar–premolar series (Fig. 2). In the living members of the Pongidae, the cheek teeth tend to be set in parallel rows or even to converge backwards, so that the third molars are closer to each other than are the third premolars. In all species of *Proconsul*,

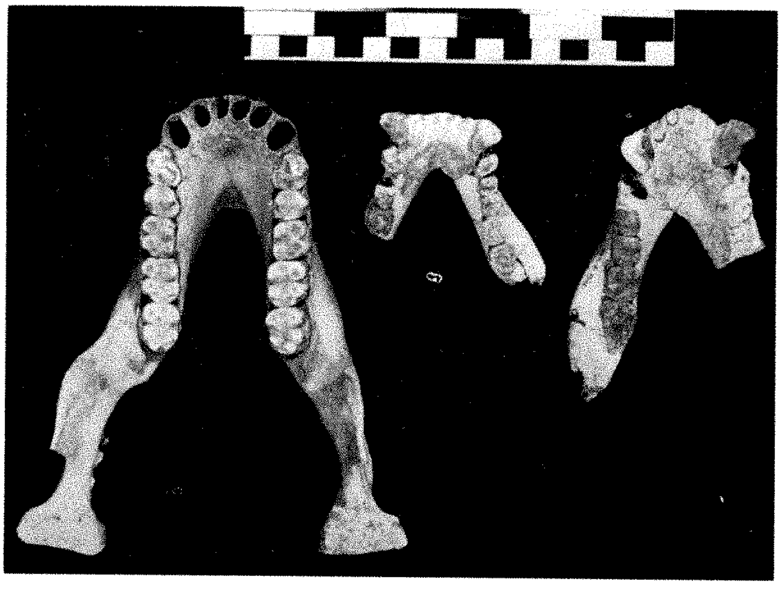

Fig. 2. Occlusal view of *Kenyapithecus africanus* mandible (centre) with *Proconsul major* (right) and gorilla (left).

there is some degree of backward divergence. In the specimen now being described, the divergence is much greater. As a result of this, although the length from the point of the canine to the back of the third molar is almost the same as in a *Proconsul nyanzae*, the overall length of the dental area is shorter and the width greater (Fig. 2). It must therefore be assumed that the face was noticeably less prognathous.

The difference in the arrangement of the teeth in the mandible as between the modern apes (Pongidae) and man, and his nearer relatives such as the Australopithecines (Hominidae), can be conveniently and graphically demonstrated by means of what I term the "basic rectangle of the mandible". This is obtained by drawing a line tangential to the anterior alveolar margins of the two central incisors, and another tangential to the two most posterior points of the third molars. When this has been done, perpendiculars are dropped from the two most posterior points of the third molars, to meet the line tangential to the incisors.

Naturally, there is some degree of individual variation within any genus or species, but, nevertheless, experiment has shown that, in spite of these minor variations, the shape of the basic rectangle is remarkably consistent for modern Pongidae on the one hand, and modern man on the other. In the Pongidae it has sides which are nearly twice as long (or in some cases more than twice as long) as the upper and lower ends. In *Homo sapiens*, however, as well as in *Homo erectus*, and in such specifically uncertain members of the genus *Homo* as the Heidelburg jaw, the basic rectangle is seen to be nearly a square, with equal, or almost equal, sides and ends.

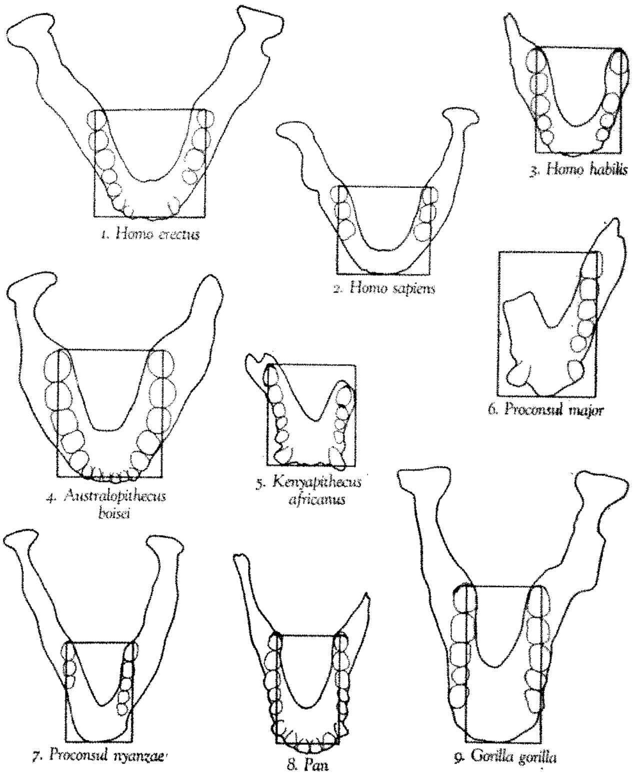
When the basic rectangle for the three species of the genus *Proconsul* is drawn, it is seen to lie somewhat intermediate between Hominidae and Pongidae. In the same way, the basic rectangle for *Homo habilis* and for the Australopithecines is not nearly so equal sided as in the more advanced Hominidae, but the shape is nevertheless clearly distinct from that which is characteristic of the Pongidae and from that of *Proconsul*.

The point of interest in Fig. 3 therefore lies in the fact that, when the basic rectangle for *Kenyapithecus africanus* is drawn, it is found to stand very close to the shape seen in *Homo habilis* and *Australopithecus*, and links it clearly with the Family Hominidae, rather than the Pongidae.

The anterior region of the mandible, on either side of the symphysis, is rounded in contour and differs very strongly from that of all known specimens of *Proconsul*, in which the structure, as a whole, suggests an inverted triangle. The mental foramina are situated a little below the half-way line on the wall of the corpus, below the fourth premolars, rather than beneath the third premolars as in *Proconsul*.

The Teeth

The incisors, as already noted, are missing. The left canine is almost perfectly preserved, but the upper half of the crown has been broken off on the right side. The first feature of importance is the angle at which the canines are set in the mandibular corpus. The buccolingual axis of the crown of the tooth is aligned much more antero-posteriorly than in any *Proconsul*, in which genus the canine teeth are usually set somewhat diagonally across the line of the molar–premolar series (Fig. 2). The alignment in *Kenyapithecus* is, indeed, remarkably like that seen in *Homo*. Next it must be noted that although the crown of the canine is high and large relative to the other teeth, it differs in several morphological respects from the corresponding teeth of *Proconsul*, and still more so from those of fossil and living Pongidae. First, the whole crown is considerably compressed bilaterally, while the anterior face is relatively much narrower than in the case of any recorded *Proconsul*. Second, the cross-section through the canines, near the base of the crown, is entirely different, with almost parallel sides. This feature has already been noted in connexion with the published mandibular fragments, where a cross-section of the root is visible in the alveolus although the crowns are broken off. This difference in the cross-section is now seen to be a basic character, associated with a wholly different type of canine crown structure in the crowns of *Kenyapithecus* which are even less conical and less like those of the pongids than in the case of *Proconsul*.



1. *Homo erectus* 2. *Homo sapiens* 3. *Homo habilis* 4. *Australopithecus boisei* 5. *Kenyapithecus africanus* 6. *Proconsul major* 7. *Proconsul nyanzae* 8. *Pan* 9. *Gorilla gorilla*

Fig. 3. Diagrammatic illustration of the difference between the "basic rectangle" of different higher primates and man (all to the same scale).

A third difference is to be seen in the relative length of the canine root. X-ray photographs show that the root of the canine is short relative to crown length, a feature which was also noted in connexion with specimen *CMH* 142 from *R*.106 in the earlier report. Fourth, the wear on the crown of the canine is quite unlike that of any *Proconsul*. There is an attrition facet down the lingual aspect, instead of along the buccal face. This feature is clearly linked with the lack of a diastema between canine and premolar, resulting in a quite different type of canine occlusion.

Both the third premolars are preserved and the following important points should be noted. The teeth are set forward in the corpus of the mandible in such a way that there is no diastema between the premolar and the canine. The anterior root of the premolars lies well in front and to the buccal side of the posterior margin of the root of the canine. This character has already been described for the *Kenyapithecus africanus* mandibles in the earlier report.

The third premolars are, moreover, rotated and set in the corpus so that they are aligned somewhat in the same general direction as the molar series, not diagonally across the corpus of the mandible, as in *Proconsul* or in the pongids. The posterior root of the third premolar is set slightly to the lingual side and not completely distal to the anterior root, but is less laterally displaced than in *Proconsul* and the living Pongidae. The crowns are composed of a single major cusp, in front of which there is a convex anterior face sloping steeply downwards. This is wholly unlike the situation in *Proconsul*, in which there is a long, low incline anterior to the cusp with a minor

cuspule on the forward edge. Posteriorly, a small fovea is present but is not very strongly developed. In all species of *Proconsul* the third premolar is rather markedly elongate with the main single cusp lying between a backward and a forward projecting region. *Proconsul* usually also has a marked wear facet developed on the buccal face of the third premolar as a result of contact with the upper canine.

Only the right fourth premolar is preserved. It is aligned in the same general direction as the molar teeth, so that its two roots are set one behind the other, a feature that was also clearly visible in *CMH* 142, described before[1]. There are two paired cusps in front of which there is a small anterior fovea, while posteriorly there is a relatively strongly marked basin, somewhat like that seen in the corresponding tooth of *Proconsul*.

The right first molar is almost perfect, but has a small area of enamel missing from its buccal face. On the left side only the posterior half of this tooth is preserved. In common with the three known *Proconsul* species, as well as many other primitive members of the Hominoidea, the first molar is markedly smaller than the second, which in turn is smaller than the third. In addition to the four principal cusps, a small hypoconulid is present. There is a rather deep pit on the lingual half of the tooth forming a valley between the metaconid and entoconid.

It is not possible to determine for certain whether a buccal cingulum was present on this tooth, because of the damage to the enamel in this region.

Both right and left second molars are preserved. The tooth on the left side is in perfect condition, but the enamel of the crown of the right second molar is somewhat pitted by weathering. The left tooth will therefore be used for description. The four principal cusps are strongly developed, while there is also a strongly marked and more or less conical hypoconulid which is set slightly to the buccal side of the mid-line. A well marked posterior fovea lies between the hypoconulid and the entoconid. As in the case of the first molar, there is a rather deep pit lying between the metaconid and the entoconid. Slight traces of an external cingulum can be seen.

The third molar has lost part of the enamel from the talonid and from part of the lingual face posteriorly. It is also somewhat pitted by weathering. The general morphology can be clearly seen in spite of the damage. The tooth is, moreover, wider anteriorly than posteriorly as in all species of *Proconsul*. It tapers towards the talonid, so that the overall appearance (viewed from above) is that of an almost triangular tooth (Fig. 2). The hypoconulid is well defined and lies slightly on the lingual side of the mid-line, with a well marked posterior fovea also on the lingual side. There are slight traces of a cingulum between the protoconid and the hypoconulid.

The length of the molar–premolar series is 50 mm measured on the right side, while the length of the series, including the canine, is 58·5 mm. The corresponding measurements on a female *Proconsul nyanzae* are 45·5 mm and 57 mm, and on a male *P. nyanzae*, 54 mm and 66·5 mm. In general dental size, therefore, this specimen lies somewhat intermediate between male and female examples of *Proconsul nyanzae*. These data are summarized in Table 1.

The new specimen of *Kenyapithecus africanus* is believed to represent a male, but it is slightly smaller in size than specimen *CMH* 142, described before[1]. It is, however, much more massive than the Songhor specimen[1] which was considered to represent a female.

Value of the New Specimen

While a detailed study remains to be carried out, it is already clear that the newly discovered mandible from Rusinga considerably enlarges our knowledge of the early Miocene members of the Hominidae. Well preserved examples of the lower teeth, with the exception of the incisors, are now available. It was already known that traces of a cingulum were present in the upper molars; and this feature is now also known to be present in the lower molars. In both upper and lower molars, however, the cinguli are very much less developed and less beaded than in any species of *Proconsul*.

It was evident from the earlier specimens that the lower canines must have had moderately large crowns, and also clear (from the cross-sections of the roots visible in the alveolus) that when the crowns became known they would probably differ from *Proconsul*, both in morphology and cross-section. This has now been shown to be the case, especially in the shape of the anterior face of the canines and their cross-section at the alveolar margin, and in the nature of the wear facets due to a different type of occlusion with the upper canines.

The lower third premolars are found to be monocuspid and morphologically not unlike those of the Pongidae. Nevertheless, this tooth differs, in several important features, from all those of any species of *Proconsul* species as well as from known *Dryopithecus* specimens. It is also set at a different angle in the mandible, with the crown more antero-posteriorly aligned and the roots set more one behind the other, instead of transversely, more as in man.

The third molar is the largest and the first molar the smallest in the molar series in which there is a resemblance to *Proconsul*. A marked character, which had been suspected from the earlier specimens but not proved, is the very strong backward divergence of the cheek teeth on either side, which must have been associated with a correspondingly shorter, less prognathous face.

Origins of *Kenyapithecus*

With the additional specimen now available, it becomes increasingly probable that *Kenyapithecus africanus* may have been derived from some earlier, but so far unknown, member of the genus *Proconsul*, possibly in Oligocene times. There are a number of characters that seem to link it with *Proconsul*, although it differs markedly in others. Because, however, it was contemporary with the earliest, so far known, *Proconsul* specimens, it seems to be a reasonable conclusion that a pre-Miocene *Proconsul*-like stock may have divided into two branches, resulting, respectively, in *Proconsul* and *Kenyapithecus*.

This new work on Rusinga Island was financed by the Donner Foundation, New York, and by the Boise Fund of Oxford.

ASTRONOMY

Polarization of Galactic Radio Emission at λ 1·25 m

SYNCHROTRON radiation from the Milky Way at radio wavelengths is linearly polarized if the magnetic field in the emitting region is in the same direction throughout the line of sight, and if the Faraday rotation is small within the emitting region Observations at λ0 21 m show polarization up to 25 per cent in a direction somewhat inclined from the perpendicular to the spiral arm, at λ0 73 m the percentage polarization is less, and the polarized area is also less, indicating that Faraday rotation is becoming important The polarization at longer wavelengths has so far remained unknown, in spite of several attempts to measure it[1-4]

The reduction of polarization at longer wavelengths might be attributed to Faraday rotation within a region of highly organized field, generally running along the spiral arm Bingham and Shakeshaft[5] show that a diverging field fits the data well, but their model, along with any other involving a smooth field, does not easily fit the data in a region of maximum polarization near $l=135°$, $b=5°$, where the high degree of polarization indicates that the line of sight traverses a large region of constant Faraday depth[5], that is inside which the rotation is zero Here the polarization falls with increasing wavelength without a corresponding rotation of the plane of polarization, and it is therefore necessary to postulate in addition that there is a less regular component of the variation of Faraday depth through the emitting region This "random" component must comprise reversals of the line-of-sight component of the magnetic field

Irregularities in Faraday depth would also show up as irregularities in the angular distribution of polarization, possibly on a small angular scale which would give an average polarization near zero over a telescope beamwidth of a few degrees Such irregularities have been found in a recent survey using the Mark I 250 ft telescope at λ0 73 m, with a beamwidth of 45′ arc (These observations will be reported separately)

Further confirmation of this physical picture has now been sought by using the telescope as a polarimeter at λ1 25 m, to survey the area $02h<\alpha<05h$, $55°<\delta<65°$, which contains the highly polarized region at $l=135°$, $b=5°$ At the longer wavelength the internal depolarization of irregularities dispersed through the emitting region would be expected to remove most of the polarization, a further reduction was expected because the irregularities would not be completely resolved by the beamwidth of 75′ arc, so that the observed polarization would be appreciably less than the actual polarization brightness temperature

In this survey, the polarimeter only detected the difference between vertical and horizontally polarized components The sidelobes of the aerial feed, which was a simple crossed dipole system, interacted with the large scale structure of unpolarized emission to give a baseline uncertain to about 3° K near the galactic plane, although small-scale polarized structure could be detected with certainty down to a polarization brightness temperature T_{pb} of about 2° K

Most of the region near $l=135°$, $b=5°$, now seems to be unexpectedly highly polarized at λ1 25 m Regions where T_{pb} exceeded 3° K are shown in Fig 1

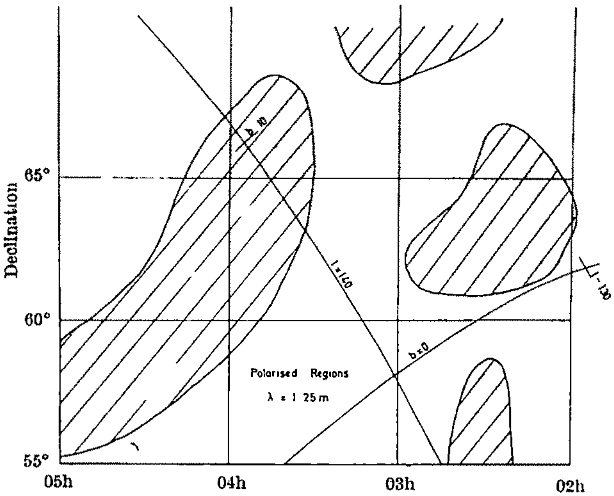

Fig 1

Inside these regions, the polarization varied rapidly with angle, often with structure unresolved by the telescope beam Nevertheless, the recorded values of T_{pb} often exceeded 8° K, while at λ0 73 m the corresponding value of T_{pb} is typically only 4° K Over all other regions of sky covered by this brief experiment at λ1 25 m, including a large region covering the North Galactic Spur, T_{pb} was found to be less than 2° K

The high degree of polarization remaining at λ1 25 m, amounting to at least 5 per cent as compared with a theoretical maximum of 70 per cent in a perfectly aligned field, shows that even for this long wavelength there is no rotation greater than about one radian within a substantial proportion of the line of sight The spiral arm is at least 500 pc thick in this direction, so that the smooth region is at least 40 pc deep Any irregularities which cause the depolarization between λ0 21 m and λ0 73 m must lie outside the uniform region, in which the product of the average electron density N_e and the line of sight component of H must be less than about $1\ 5\times 10^{-8}$ gauss cm^{-3} The observation that adjacent lines of sight, separated by 1 25°, often have different net polarizations is probably a consequence of a variable Faraday rotation in front of the smooth region

If we suppose that the field strength is about 3×10^{-6} gauss and that it is aligned along the spiral arm in the direction $l=70°$, then the line of sight through the polarized region crosses the field at angles up to 30° The electron density must then be less than 0 01 cm^{-3} Even if the field follows the direction $l=50°$, the wide angle of sky covered by the polarized regions suggests that the electron density must still be less than 0 03 cm^{-3} in a considerable region of the spiral arm

These averages of electron density refer to averages through a line of sight extending for about 50 pc, one may infer that the values around 0 1 cm^{-3} deduced from the absorption of lower frequency radio waves[6] refer to an average through discrete concentrations rather than a uniform value throughout the spiral arm

Spectrum of the Radio Source 4C 50.11/NRAO 150

MOST extra-galactic radio sources have a spectrum which over a limited frequency range is of the form $S\propto\nu^{-\alpha}$, where S is the flux density and ν is the frequency. The spectral index α is usually constant over a considerable frequency range, which implies a straight spectrum when plotted logarithmically, the average value over all sources being 0.75 with a range from about 0.2 to 1.3. For some sources, however, α changes slowly with frequency with the result that the spectra are concave or convex[1-3]. It is believed that the radiation is produced by the synchrotron mechanism, where energy losses by the electrons can lead in time to an increase in the slope[4,5] and where, in addition, different component sources may contribute to the overall spectrum. High frequency observations by Dent and Haddock[6] showed that two sources, *3C* 84 (NGC 1275, a Seyfert galaxy) and *3C* 279 (a quasi-stellar source), have spectra which decrease in flux density from about 38 MHz towards higher frequencies, but beyond 3,000 MHz the slope of the spectrum is positive. This suggested the presence of a small diameter component which had a low frequency cut-off due to synchrotron self-absorption[7] and stimulated a search for other sources with similar spectra. Kellermann (personal communication) has recently observed fourteen sources with irregular spectra, of which some have a tendency towards these latter characteristics, but so far there have been no published spectra similar to *3C* 84 and *3C* 279. Recent observations at the frequencies of 3,200, 6,600 and 10,600 MHz, however, using the 150 foot telescope of the Algonquin Radio Observatory, when combined with the observations by other observers[8-11], have shown that the source *4C* 50.11/NRAO 150 is of this form but with the addition of two apparent peaks at frequencies of about 350 and 9,000 MHz. The source is included in the list by Kellermann, but details of the characteristics failed to show up because of the omission of low frequency observations and the new measurements between 5,000 and 15,000 MHz.

If it is assumed that the spectrum is the result of the superposition of non-thermal components and that the peaks are the result of components which have an optical depth sufficiently great to produce synchrotron self-absorption, then it is possible to distinguish three components, designated *A*, *B* and *C*. The resulting spectrum is shown in Fig. 1, which also shows the spectra of *3C* 84 and *3C* 279. At low frequencies, there is some evidence for absorption resulting from ionized hydrogen in the galactic plane, amounting to 2 dbar or more, obtained by assuming the single component *A* with a straight spectrum, and taking the upper limit of 2 flux units at the frequency of 22 MHz (Costain, private communication). This seems to be reasonable for the direction of the source, which has galactic co-ordinates $l^{II}=150°$, $b^{II}=-2°$. The relative flux densities of *B* and *C* and the slope of *A* were deduced from the long baseline measurements of Palmer *et al.*[12] at 2,600 MHz, where the observation of fringes from the source is taken to imply that *B* has an appreciably greater flux density than *C* at this frequency and therefore that *A* must also decrease rapidly with an index of about 1.3.

Although the peaks in the spectrum may suggest that the source is variable, no variations greater than the random errors of about 10 per cent were observed during the period February–August 1967, and the spectrum as shown is believed to be correct for the present epoch. Unfortunately, the source is situated close to the galactic plane so that obscuration may make optical identification difficult, and there is no apparent correlation with any object on the Palomar Sky Survey. In addition, the proximity of the source to the galactic plane could produce some confusion affecting the accuracy in determination of the flux density at 38 MHz even though the nearest source in the *4C* survey (*4C* 51.11) is more than 1° away.

The observation of fringes in the long baseline observations also indicates that *B* has a diameter less than about 5×10^{-2} s of arc. This is consistent with the assumed spectrum, which for a cut-off frequency of 200 MHz implies that, even if the magnetic field is taken to be as high as 10^{-2} gauss, the diameter is less than 2×10^{-2} s of arc. The diameter of component *C* is probably even less, as evidenced by the much higher cut-off frequency. The small diameter for *B*, the comparatively low flux density and the high cut-off frequency are also evidence that it cannot be an H II region. The same is probably also true for *C*, and confirms the assumption that the components are a result of a non-thermal mechanism. The same arguments can also be used to suggest that the source is probably not situated in the galaxy. The position of component *B* as determined from the NRAO observations at 1,400 MHz (ref. 10), and that determined for *C* from the present observations at 10,600 MHz, seem to be separated by 45 s of arc, although the combined errors amount to 33 s of arc. These are shown in Fig. 2, where there is also plotted the source position from the *4C* survey at 178 MHz (ref. 9). The steeper spectrum for component *A* suggests an older and possibly a more extended source than the two apparently more recent components with small diameter. It is tempting to suggest a model for the source, consistent with the observations, which consists of an older and comparatively extended region or halo, corresponding to component *A* together with two small diameter components *B* and *C* which are probably very recent ejections.

If the general interpretation of these results is accepted, it suggests that the source may be a radio galaxy or quasar in the early stages of development, and leads to the following comments.

First, if components *B* and *C* are young sources, then the spectral index of 0.5 is very much steeper than the value of 0.25 assumed by Kellermann[5] to be the initial spectrum for a young radio source. The value of 0.25 was previously chosen, because it appeared to be the smallest value for the sources considered, but could possibly have been due to the presence in the source of a number of components. It is possible that sources do not develop in the comparatively simple way that has been suggested. For example, acceleration mechanisms, resulting in the development of less steep spectra, may be active following

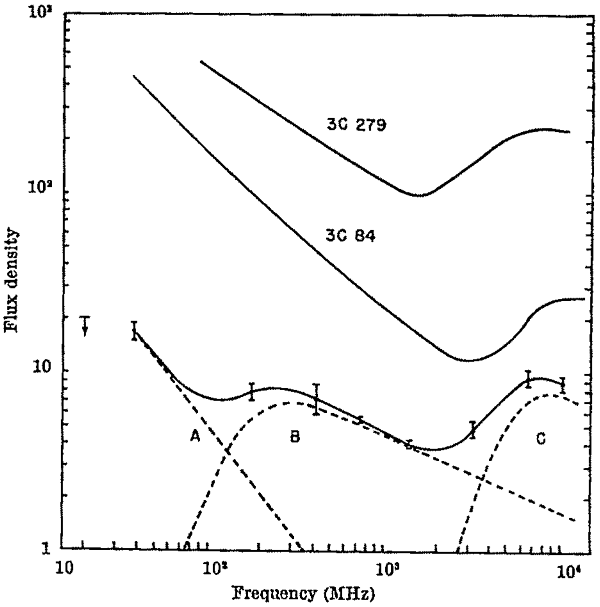

Fig. 1. The spectrum of the radio source *4C* 50.11/NRAO 150 showing the suggested three components *A*, *B* and *C*. The spectra of *3C* 84 and *3C* 279, displaced along the vertical axis, are included for comparison purposes.

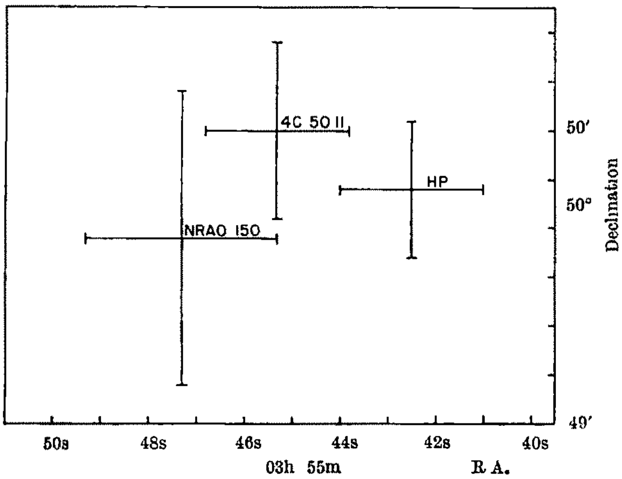

Fig 2 The position of the source 4*C* 50 11/NRAO 150 as determined from the 4*C* survey at a frequency of 178 MHz, the NRAO survey at 1,400 MHz and the present results (HP) at 10,600 MHz The arms of the cross represent error limits

the initial ejection as has been suggested by Ryle and Longair[13] In any case, there is no evidence that the energy spectrum of electrons produced in the initial ejections is the same for all sources There remains the alternative that the source may be older and have a large linear size, but the distance would have to be very great to account for the smallness of the angular size

Second, the results demonstrate the importance of long baseline observations, when combined with detailed knowledge of spectra, for resolving the structure of radio sources This is demonstrated in the present case where it is possible to separate with some precision the components *B* and *C* And, as a corollary, statistics involving the classification of sources into single, double, multiple, core and halo and so on which are derived from interferometer measurements at a single frequency may not be significant when applied to radio sources in general, and in particular to those with an apparently flat spectrum or where observations are not taken at sufficiently close frequency intervals to define the spectrum accurately In fact, for the model proposed, the present source may well be classified under any one of these headings depending on the frequency at which observations are made For example, at a frequency of 3,700 MHz the source might appear to have two components of equal intensity, on either side of this frequency to have two unequal components, at near to 1,000 and 10,000 MHz to be a single source, and at a few hundred MHz to be a point source with a more extended region If the source ages according to current theories, the points where synchrotron self-absorption occurs are expected to move to lower frequencies so that in time the source may appear as triple over a large frequency range

The source is suggested as one worthy of further investigation with long baseline radio interferometers, and it is still possible that the source could be observed at optical wavelengths

PLANETARY SCIENCE

Semi-annual Variation in Upper Atmosphere Density

I RECENTLY reported[1] the results of an analysis that indicated a semi-annual variation in air density at a height of 190 km in 1966–67, with the unexpectedly large maximum to minimum ratio of 1 45 The maxima were in April and October, the minima in January and June, as usual Newell[2] has subsequently discussed these results, and has left two open questions on which I should like to comment

First, Newell remarks that the enhanced semi-annual variation at a height of 190 km cannot be accounted for by Cook's explanation[3] of the semi-annual variation at a height of 1.100 km, in terms of variations in the concentration of helium at heights near the turbopause (about 120 km) In one respect Newell's remark is quite true. there is very little helium at 190 km—certainly not enough to give rise to a variation by a factor of 1 45 However, the essence of Cook's suggestion, namely, that variations at heights as great as 1,100 km may be attributable to effects at heights as low as 120 km, is strengthened by the finding that an important semi-annual variation extends to a lower level than previously known—190 km It seems quite likely that the semi-annual variation in 1966–67 was appreciable down to 150 km, where synoptic measurements are very scarce, and possibly even to 120 km.

The second question left open in Newell's communication concerns Anderson's controversial hypothesis[4] that the semi-annual variation can be ascribed to the influence of latitude and is not a true time-variation Anderson's hypothesis can be disproved if analysis of the orbits of satellites at several different heights and latitudes yields similar variations of density with time Such evidence is now available Recent results[5] from Midas 2, which has a circular orbit at a height of about 480 km and an inclination to the equator of 32°, show time-variations that are in excellent agreement with those obtained[1,6] from the near-polar orbits of Secor 6 at a height of 190 km and Echo 2 at a height of 1,100 km

Fig 1 gives the values of air density obtained[5] from Midas 2, corrected to a level of solar activity corresponding to a 10 7 cm radiation flux of 125×10^{-22} W m^{-2} Hz^{-1} The values are averages over latitudes between 32° N. and 32° S The two "spikes" indicate times of strong geomagnetic disturbance, when values were excluded. It should be noted that the absolute values of density in Fig 1 are subject to a possible bias error because the mass of the satellite is not exactly known; but this does not affect the validity of the variations Fig 1 shows that, if the maximum and minimum densities in the semi-annual variation are defined as values sustained over 30 days, the maximum to minimum density ratio was 2 1 at a height of 480 km in 1966–67 It is also of interest that on all occasions when the time resolution is adequate (that is, after April 1966) the minima are double; the "main" minima in January and July are accompanied by subsidiary minima in March and May It remains to be

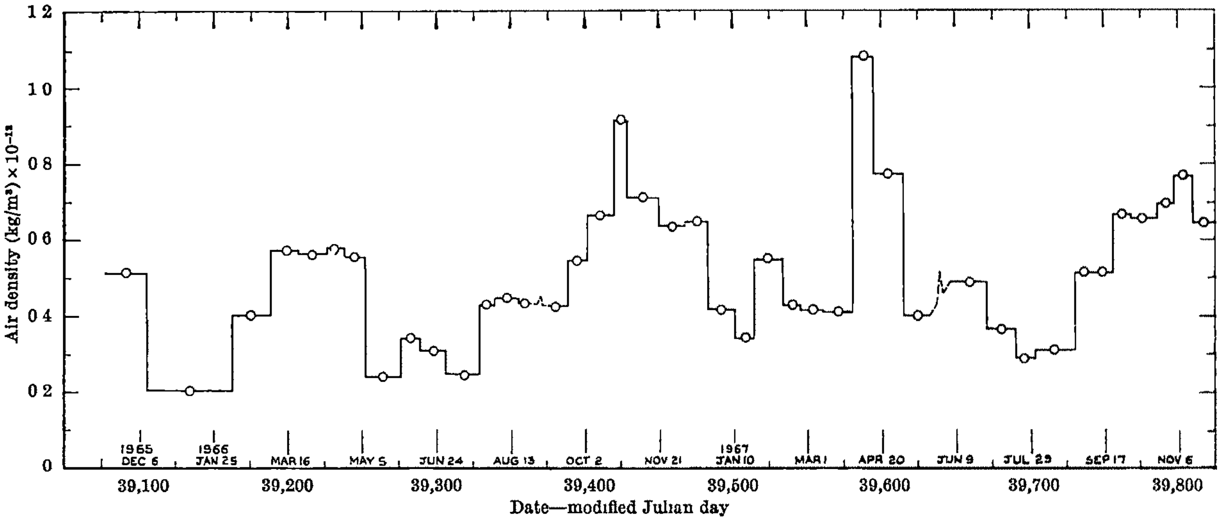

Fig. 1. Values of air density at a height of 480 km, obtained from the orbit of Midas 2, corrected to a mean level of solar activity

seen whether this is a regular pattern or merely a chance effect.

Solubility of Barium Sulphate in Sea Water

Most of the elements in solution in sea water are present in smaller amounts than would be expected on the basis of solubility equilibria. The concentrations of many of these elements are controlled by other processes such as ion exchange, adsorption and biological removal. There are, nevertheless, several elements for which solubility may be an important factor affecting abundance and distribution in parts of the ocean. These generalizations are based on comparisons[1,2] of the observed concentrations of elements in sea water with those which would be expected from a consideration of their solubility. Even when reliable abundance data are available, however, exact comparisons are precluded by the lack of accurate, experimentally determined values for the solubility in sea water of all but a few compounds and the approximate nature of theoretical calculations which must usually be made using assumed values for the activity coefficients of ions in this complex solution.

There is thus considerable interest in obtaining values for solubilities in sea water by direct measurement, especially for the less soluble compounds which may in some circumstances limit the concentrations of certain elements. This interest extends to a more diverse range of compounds when atypical environments are considered, whether natural, as in some isolated basins, or artificial, as in polluted waters. The presence of dissolved ions in natural waters precludes the use of methods such as those based on conductance measurements, which have been most widely used to measure the solubility of sparingly soluble compounds in pure water. We describe here a radiochemical method for determining the solubility of barium sulphate in sea water, the technique, although well known to chemists, does not seem to have been applied previously to sea water. We chose barium sulphate for the initial investigation because in studies of barium in the ocean there has been some discussion[3,4] of the possibility that the limited solubility of its sulphate (the least soluble compound formed with a major anion in sea water) might play an important part in influencing its distribution. This communication gives the results of preliminary experiments which indicate the scope and value of the method.

Initially, experiments were carried out using barium sulphate labelled with barium-140. The results were unsatisfactory in that there was no clear indication that equilibrium between the solid phase and the solution was attained and control experiments using pure water gave low results. Anomalous results for the solubility of similarly labelled barium sulphate in water have been reported by Spitsyn *et al.*[5] although their findings were not confirmed by other workers[6-7].

Experiments using barium sulphate labelled with barium-133, prepared by a method similar to that described by Rosseinsky[8], have given more satisfactory results. An amount of the solid in considerable excess of that needed to give a saturated solution was stirred with sea water in a closed glass flask at 20° C. The sea water was surface water ($S = 35‰$) from the English Channel, collected 22 miles from Plymouth and filtered through a membrane filter of retentivity about 0·5μ. Aliquots of the supernatant solution were removed through membrane filters at intervals and the radioactivity of barium-133 in a known volume was measured and compared with that of a known amount of the labelled compound dissolved and counted in the same conditions.

In three separate experiments, the radioactivity of the supernatant solution reached an essentially constant level after a time which varied from 5 to more than 10 days, apart from a few irregular high values attributable to failure of the filtering arrangements. On the basis of sixteen separate measurements made during these experiments during the period when steady state conditions were established, the mean value for the solubility of barium sulphate in sea water at 20° C was found to be 81 μg/l. (48 μg of barium/l.) with a standard deviation of 5·8 μg/l. In another experiment, a steady state was not established, however, the apparent solubility at the end of the experiment was similar to this value. To check the validity of the method, duplicate experiments were made in a similar way using water which had been deionized and then distilled in a silica still. The solubility found was 2·30 ± 0·22 mg of $BaSO_4$/l. at 20° C, in satisfactory agreement with accepted values such as that of Rosseinsky[8] (2·42 mg/l. at 25° C).

In interpreting the results for sea water it has been assumed that any barium originally present in solution (probably less than 10 μg/l.) would substantially exchange with the labelled solid phase during the experiment so that the amount of radioactive barium present in solution in steady state conditions gave a measure of the total barium present in solution. Experiments in which unlabelled barium sulphate was shaken with sea water saturated with labelled barium support this assumption.

The solubility of barium sulphate in sea water at 20° C and 1 atm found in these experiments is almost identical to that calculated by Chow and Goldberg[3] (52 μg of barium/l.) and appreciably higher than that calculated by Krauskopf[1] (about 30 μg of barium/l.). This gives some support to the values of activity coefficients assumed by Chow and Goldberg[3], although too much weight should not be placed on the closeness of agreement until the work has been extended to samples of sea water from other sources. Work on these lines will be continued and experiments will be made at the lower temperatures which are more characteristic of ocean waters. The results reported here, in conjunction with determinations of barium in sea water[3,4,9], confirm that barium is undersaturated in the surface waters of the ocean.

This work forms part of an investigation supported by the Natural Environment Research Council. One of us (N. J. M.) thanks the Council also for the award of an advanced course studentship.

Significance of Stylolites in Dolomitic Limestones

STUDIES of Western Australian stylolitic limestones reported here strongly support the widely held view that stylolites form by pressure-solution[1-3], and agree with suggestions that pressure-solution can significantly reduce the volume of carbonate formations. Furthermore, these results indicate that selective pressure-solution of calcite in dolomitic limestone can cause relative enrichment in dolomite, and this allows speculation that the process can form pure dolomite rocks (dolostones) from some dolomitic limestones. Calcite is likely to be released for the cementation of nearby formations, and thinning in the limestone bodies may induce new structures in overlying strata.

Many data relevant to this study were provided by cores of the Ordovician Thangoo Limestone, made available by West Australian Petroleum Pty., Ltd., from their Roebuck Bay No. 1 Well in the Canning Basin (lat. 18° 09′ 30″ S., long. 122° 27′ 30″ E.). The rocks come from the interval between 3,354 and 4,000 ft and range from limestones (micrites and intrasparites with less than 10 per cent replacement dolomite), through dolomitic limestones (micrites and pelsparites with 10 per cent or more replacement dolomite), to fine-grained dolostones (entirely dolomite, without palimpsest textures to demonstrate replacement).

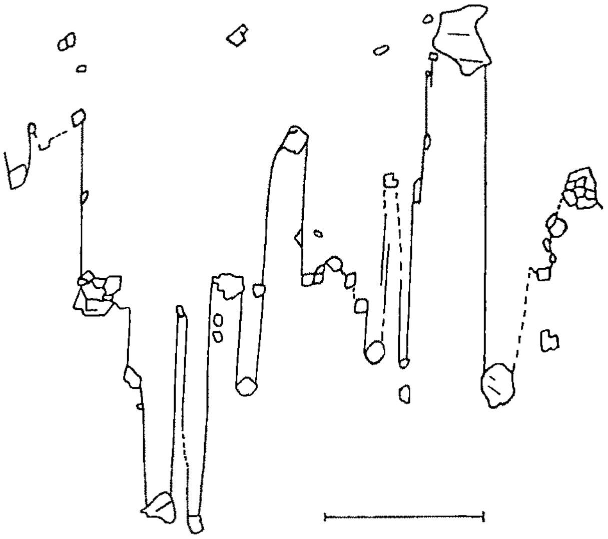

Fig. 1. Stylolite from intrasparite between 3,515 and 3,522 ft. Dolomite grains or aggregates occur at the ends of most columns, but are sparse elsewhere. A few grains show cleavage. Drawn to scale from thin section. The horizontal line represents 1 mm.

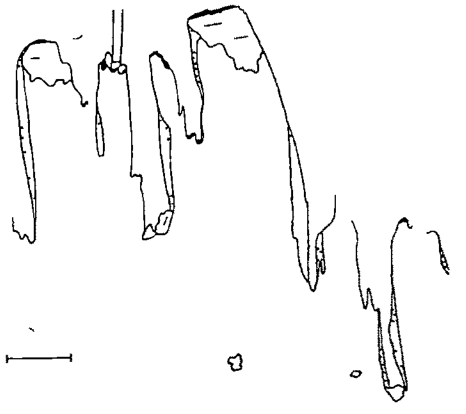

Fig. 2. Stylolite from intrasparite between 3,420 and 3,426 ft. Sparry calcite (stippled) occurs along columns, dolomite grains (some with cleavage) at ends of columns. Clay is shown black. The column of a second stylolite interferes near top left. Drawn to scale from thin section. The horizontal line represents 1 mm.

Small stylolites, usually with an amplitude of 1–5 mm, are numerous in the limestone and dolomitic limestones, but have not been recognized in the dolostones. The stylolites are partly defined by argillaceous material and commonly have dolomite grains at the ends of columns, even if dolomite is sparse elsewhere in the rock (Fig. 1). A few stylolites also contain narrow calcite veins along the sides of columns (Fig. 2).

The interrelationships of the calcite, dolomite and stylolites in the Thangoo Limestone are important, for two interpretations of fabric in stylolite-bearing dolomitic limestones are current. One view is that stylolites act as migration channels for subsequent dolomitizing solutions[4,5], and the other is that the dolomite precedes the stylolites and is concentrated along them by pressure-solution of the calcite matrix[6]. The latter view is indirectly supported by discoveries of Recent and contemporary dolomitization of limestones near the surface[7], for these discoveries suggest that dolomite formed before stylolites in many of the old rocks. The dolomite grains in Figs. 1 and 2 evidently preceded the stylolitic columns and formed protective caps at their ends. By contrast the sparry calcite along the sides of columns in Fig. 2 was emplaced during or after their development, and may have come from calcite dissolved at the ends. The original composition and texture is therefore retained only in rock between the stylolites.

The minimum section loss of Thangoo rocks resulting from pressure-solution was estimated by Stockdale's method[2] of summing the amplitudes of the stylolites. The resulting figures are approximate, for measurement is complicated by coalescence of stylolites, and the section loss represented by a stylolite may be several times its amplitude No loss from pressure-solution can be recorded for the dolostones because they lack recognizable stylolites, but the minimum loss for dolomitic limestone varies from 10 per cent to 20 per cent, and for other limestones from 30 per cent to 50 per cent Thus rocks which were originally highly dolomitic apparently lost less volume than those which were more calcitic, confirming the interrelationships indicated in Figs 1 and 2 The thickness of Thangoo Limestone intersected by Roebuck Bay No 1 (646 ft.) probably represents a loss of at least 130 ft, perhaps far more These figures are not excessive when compared with those accepted for other stylolitic limestones[1-3,8,9]

It is clearly important to seek the destination of the large volumes of dissolved calcite Initially, the calcite may precipitate elsewhere in the limestones themselves, but after all pores have been filled it must be expelled and may enter porous, less soluble rocks in the column, such as sandstones The expulsion of pore fluids and dissolved calcite in these conditions has already been commented on[3,9]

Pressure-solution is certainly not restricted to calcite, for it has been reported elsewhere in dolomite, and in siderite, gypsum, sandstone, quartzite and volcanic rock[1,10] Stylolitic boundaries, however, are found between dolomitic and calcareous portions of many Palaeozoic dolomitic limestones, and the physico-chemical conditions which allowed dolomite to persist while calcite dissolved may therefore have been widespread If so, the consequences are likely to have been both mineralogically and structurally significant The evidence indicates that selective pressure-solution of calcite can increase the proportion of dolomite in dolomitic limestones, and we can speculate that some dolostones form in this way Selective pressure-solution can also release calcite for the cementation of nearby formations It follows that sedimentary bodies derived by partial or complete removal of calcite from patchily dolomitized limestone beds will not only be thinner than their precursors, but very different in shape Faulting and folding in overlying strata may well accompany the thinning

Origin of the Lake Constance Basin

Lake Constance is one of the largest freshwater lakes of Central Europe and is located in south-western Germany, bordering Switzerland and Austria (Fig. 1)

The lake has a surface of 540 km^2 and a maximum depth of 252 m; its longest axis is 69 km and the maximum

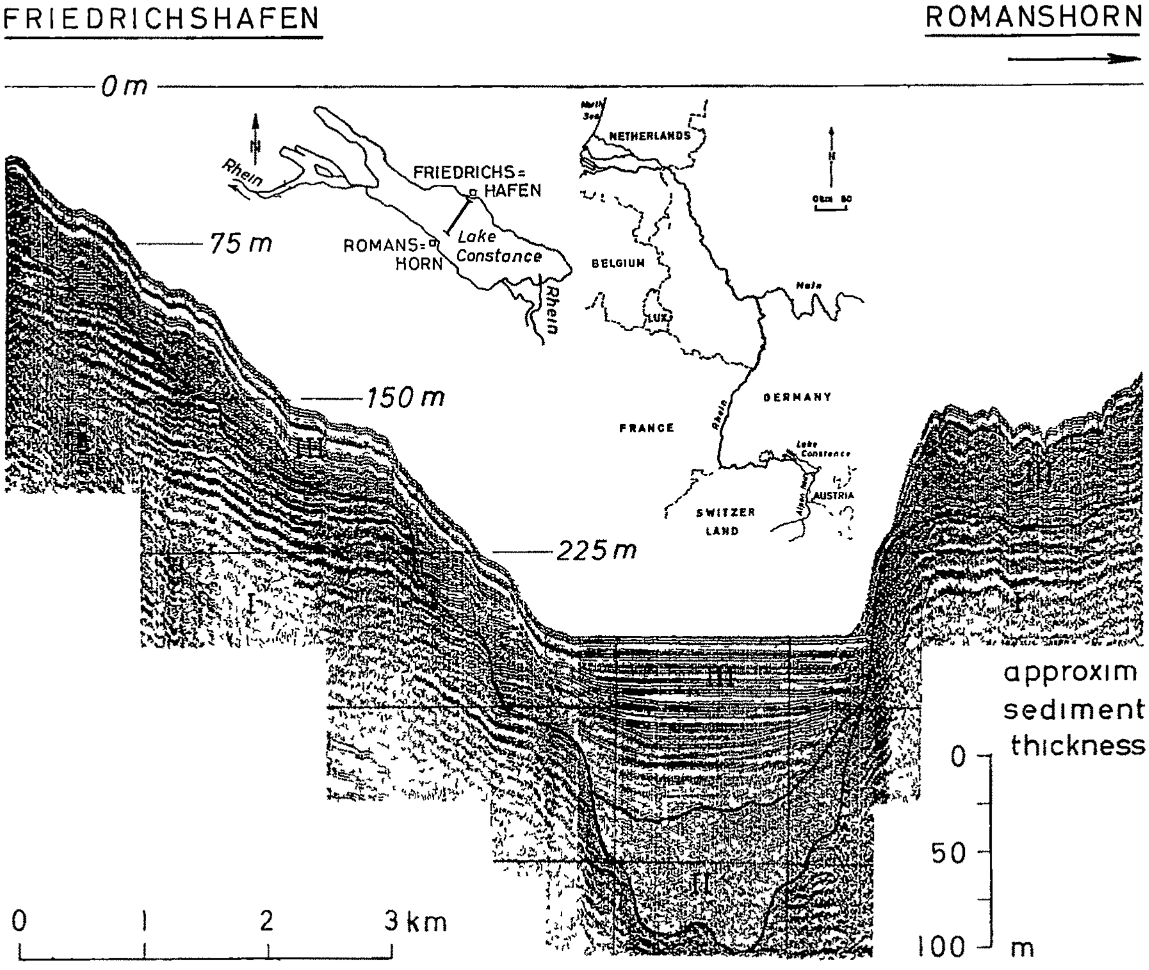

Fig 1 Continuous seismic profile (cross-section) between Friedrichshafen and Romanshorn

width about 15 km. There have been two principal theories of the origin of the lake and its basin (a) the structural theory, and (b) the glacial theory There is also (c), a combination of (a) and (b)

In connexion with a large scale research project concerned with the sediments of Lake Constance[1-4], an extensive continuous seismic survey of the sub-bottom structures was carried out during November and December 1967 Thirty-five cross-sections and two longitudinal sections were surveyed Measurements were made using a Bolt air gun with a 1 in ^{3} chamber at a pressure of about 2,000 lb /in ^{2} The air gun was triggered every 1 7 s and was towed near the surface mounted in a rubber inner tube A series of hydrophones mounted as an eal was towed about 100 ft behind the vessel The cruising speed of the vessel was 8 km/h

A typical cross-section of the central part of the lake between the towns of Friedrichshafen and Romanshorn is shown in Fig 1 On this profile, three chief principal geological units can be recognized III, a well-defined horizontally bedded youngest unit which reaches its maximum thickness in the deep parts of the lake basin, II, an older unit, underlying unit III with diffused ill-defined reflexions, and I, the oldest unit with well-defined somewhat undulatory reflexions forming the framework of the lake basin

Unit I, in which the lake basin was eroded, represents the Tertiary molasse This unit can be correlated directly with many Tertiary outcrops along the shoreline of the lake. Unit II probably consists of Late Pleistocene heterogeneous glacial material (till), which in turn is overlain by unit III representing postglacial (Holocene) fine-grained, well-bedded lake sediments The three lithological units can be traced throughout the central and western parts of the lake In the eastern part, however, the relations are less clear, probably because of the considerable amount of deltaic sediment deposited by the River Rhine[2]

This seismic survey seems to indicate clearly that the Lake Constance basin is the result of glacial erosion rather than of structural deformation The results of the survey confirm the glacial theory of formation of the lake basin postulated by Wagner[5] Recent seismic surveys in the vicinity of the lake evaluated by A Schreiner, in a lecture given at Heidelberg in 1966, have also ruled out the possibility that tectonic movements were being involved in the formation of the lake basin

This work was supported by a grant from the Deutsche Forschungsgemeinschaft Seismic equipment and personnel were made available by the Bundesanstalt fur Bodenforschung in Hanover The Anstalt fur Bodenseeforschung der Stadt Konstanz put the research vessel August Thienemann at our disposal

Late Palaeozoic Glacial Facies and the Origin of the South Atlantic Basin

IN an attempt to add detail to the established picture of glaciation in the southern hemisphere during the Late Palaeozoic, we have studied tillites and associated rocks in Antarctica, Africa, South America and the Falkland Islands in the past few years[1-4] As well as determining the direction of ice movement from directional properties of the rocks, we have subdivided the strata into several environmentally significant facies These distinct lithological types are further restricted geographically in such a way that their distributions add information on palaeogeography For example, linear sand bodies interpreted as glacial eskers are interbedded with tillite in the western Falkland Islands[5] These deposits pass laterally into a thick, massive envelope of tillite and associated turbidites in the eastern portion of the Falklands, which suggests that terrestrial ice occupied the west while, farther east, glacial-marine accumulation took place in deeper water. Similar approximate palaeogeographic reconstructions from tillite facies can now be made for widely scattered parts of the glaciated continent of Gondwanaland

Marine fossils are not extensively known from the glacial sequences, but they have been described from Brazil, Argentina and South West Africa[6-8] Usually these sequences are considered to be of shallow marine origin A marine interpretation is also preferred for very thick accumulations (up to more than 2,000 m) known from several areas in the South Atlantic region A catchment area of considerable depth is suggested by the great thicknesses, and, moreover, strata associated with the tillite in this facies are those commonly associated with deep-marine downwarps—turbidites and deposits from related kinds of mass-movement processes These thick sequences are referred to here as being of deep-water glacial-marine origin, but they do not contain fossils and it remains to be proved that they are truly marine

Fig 1 shows a geographic reconstruction of a portion of Gondwanaland in Late Carboniferous to Early Permian time The locations and orientations of Africa and South America are based largely on the geodetic fit at the 500 fathom isobath[9], and Antarctica is fitted using the same feature The effects of post-Aptian disruption of the linear Andean–West Antarctic trend to form the present Scotia Arc[10] have been removed from the map Extensive right-slip faulting, here tentatively suggested to explain relative movement between East and West Antarctica since the end of the Palaeozoic, has also been removed Any reconstruction of this kind for South America, Antarctica and Africa leaves a broad oceanic region at the join area The present attempt minimizes the size of this region at about 5×10^6 km^2

Distribution of three glacial facies in Gondwanaland is also shown in Fig 1 Facies represented are terrestrial till, shallow-water glacial sediments, interbedded with continental deposits, and deeper-water strata, probably of glacial-marine origin The most striking characteristic of the map is the rough matching of facies boundaries across continental boundaries This provides evidence on a detailed scale in support of continental drift The present wide separation of these rocks may have resulted from drift of the continents away from each other

It can also be observed that the probable deep-marine facies occurs only in a belt around the margin of the present South Atlantic basin Glacial sediments laid down in shallow water and terrestrial tillites are located progressively farther from the basin margins The generalized palaeogeographic interpretation is that of ice bodies flowing toward and discharging into a deep, centrally located sea or series of seas on the site of the southern Atlantic basin Evidence from these rocks thus suggests that a portion of the South Atlantic basin was already in existence in Late Palaeozoic time The deep-water portion of this basin is succeeded to the north by deposits of the shallow-water and terrestrial regimes, suggesting that the basin did not extend north of about 32° S latitude, and that Africa and South America were still attached

The suite of glacial rocks referred to here constitute part of the well known southern hemisphere Gondwana Series This is a thick, regressive sequence ranging in age

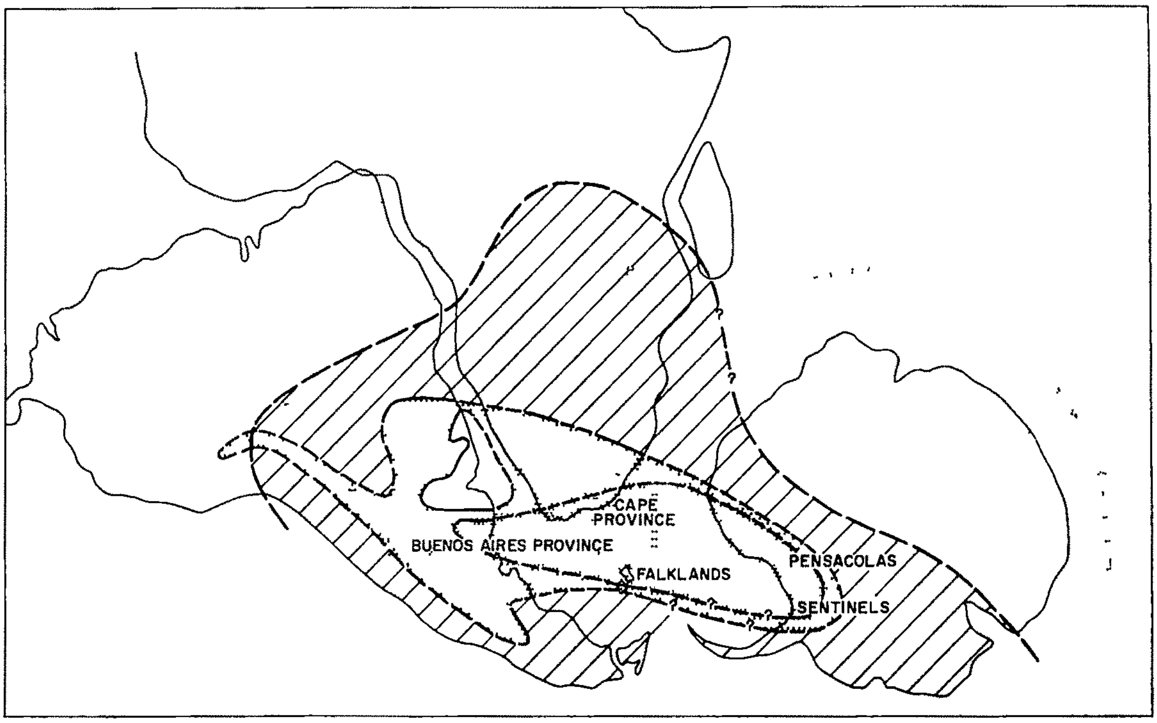

Fig. 1. Reconstruction of a portion of Gondwanaland in Late Palaeozoic time. The diagonally lined area represents the distribution of terrestrial tillites and related deposits, the open stippled area represents the region of shallow-water glacial and associated continental deposits, and the close stippled region represents the area of deep-water deposits, in part glacial-marine and marine. The unpatterned areas are presumed upland source regions

from Early Devonian (possibly Silurian) at the base, to Triassic sedimentary and Jurassic intrusive and extrusive rocks at the top. Basal marine strata lie on crystalline basement rocks and pass gradually upward into continental beds in the regions of continuous accumulation. Elsewhere, unconformities are developed, indicating intermittent uplift and subaerial erosion in marginal areas of the basin. In the areas studied, the earliest marine incursion is judged from the nature of the strata laid down to have been epicontinental, most of these deposits are probably not of deep-marine origin. Deep-water deposition marginal to the South Atlantic basin seems only to have begun with sedimentation of the glacial sequences in Late Carboniferous and Early Permian time, but timing cannot yet be determined precisely in most cases.

The presence of such a sizable waterbody in this region may have contributed to the onset of Late Palaeozoic glaciation. In order for glaciation of continental dimensions to begin in the Late Palaeozoic there must have been abundant precipitation, and thus evaporation from a large source. In a fully reconstructed Gondwanaland, the most centrally located portions of the supercontinent would lie at distances of thousands of kilometres from the peripheral ocean basins. Glaciation would therefore probably be confined to coastal areas. Development during the Middle and Late Palaeozoic of first an epicontinental and then a deeper basin penetrating to the interior of the continent would, however, provide abundant moisture to even the most remote parts of the supercontinent. Even so, Late Palaeozoic glaciation would probably not have occurred if a vast Gondwanaland had not been insulated at the time in high latitudes. The data of palaeomagnetism[11] indicate that the supercontinent drifted across the polar region at approximately the same time that the South Atlantic began to form. Without such a fortuitous arrangement, Late Palaeozoic continental glaciation might not have occurred at all.

PHYSICS

Motion of a Fluid through a Vibrating Pipe

I HAVE shown[1] that for the laminar flow of a fluid through a pipe the friction factor is increased when the pipe is vibrated in a direction perpendicular to the flow, the magnitude of the increase depending on the vibration amplitude and frequency, pipe diameter, kinematic viscosity and mean flow velocity. The purpose of this communication is to investigate the cause of this effect for small vibrations.

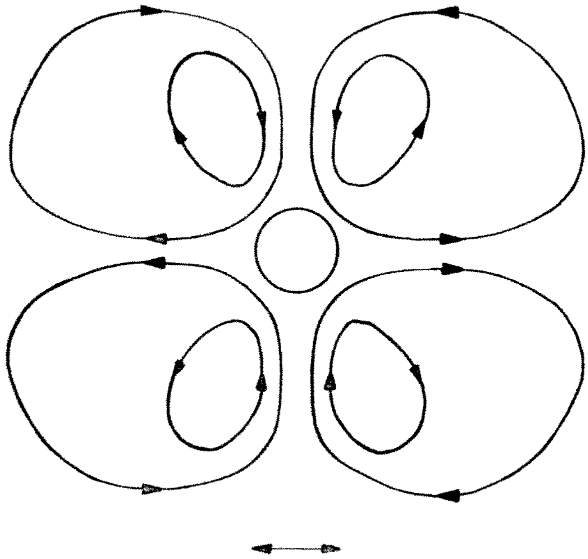

Fig. 1.

Andrade[2] and others have shown that when a stationary cylinder is subject to sound waves of sufficient intensity a system of vortices is formed around the cylinder according to Fig. 1. Schlichting[3] has analysed the case of two coaxial cylinders where the inner one vibrates in a direction at right angles to its axis. A system of vortices similar to those obtained by Andrade is formed.

F. G. McLaren and myself have subjected a cylinder containing air to transverse vibrations. A similar system of vortices was seen with the aid of smoke, and also with aluminium powder on water (Fig. 2). Such a secondary flow could give rise to an increase in friction factor when a fluid flows through a pipe.

For the case of a vibrating cylinder coaxial within another, Schlichting[3] obtained in polar co-ordinates (r,φ) the expression

$$\psi = A\left[\frac{C_1}{r^2} + C_2 + C_3r^2 + C_4r^4\right] \sin . 2\varphi$$

where

$$A = -\frac{3}{2}\frac{S^2n}{R}$$

for the stream function of the steady flow between the cylinders, where the vibrating cylinder of radius R had an amplitude S and angular frequency n.

Vibrating the outer cylinder and making the radius of the inner cylinder tend to zero gives the expression for the stream function

$$\psi = \frac{AR}{2}(x^4-x^2) . \sin . 2\varphi$$

where the radius of the outer cylinder is R and the dimensionless radius x is equal to r/R.

We can write the Navier Stokes equation in cylinder polar co-ordinates (r, φ, z) for the z direction (velocity W) in dimensionless form where we substitute

$$u = -\frac{1}{r}\frac{\partial\psi}{\partial\varphi}, v = \frac{\partial\psi}{\partial r}, \psi = \nu . \psi a, \ W = W_0w, r = xR$$

to give

$$\frac{1}{x}\left[\frac{\partial\psi a}{\partial x}\frac{\partial w}{\partial\varphi} - \frac{\partial\psi a}{\partial\varphi} . \frac{\partial w}{\partial x}\right] = -\frac{R^2}{\mu W_0}\left(\frac{\partial P}{\partial z}\right) + \nabla^2 w$$

where

$$\nabla^2 = \frac{\partial^2}{\partial x^2} + \frac{1}{x}\frac{\partial}{\partial x} + \frac{1}{x^2}\frac{\partial^2}{\partial\varphi^2}$$

and ν is the kinematic viscosity.

To solve this equation we assume that the flow is described by the following equations, where w_0 refers to the velocity in an unvibrated pipe in the laminar region.

$$\psi a = 0 + K\psi_1$$

$$w = w_0 + Kw_1 + K^2w_2 + \ldots .$$

where

$$K = \frac{AR}{\nu}, \psi_1 = \frac{1}{2}(x^4-x^2) \sin 2\varphi, \ w_0 = 1-x^2$$

Following the general reasoning adopted by Dean[4] for a similar type of solution for flow in curved pipes, the second term of the series for w is given by

$$w_1 = \left[\frac{5x^2}{48} - \frac{x^4}{6} + \frac{x^6}{16}\right] \cos . 2\varphi$$

To determine the rest of the terms is a lengthy process, but the problem is to determine the effect of vibrations on the friction factor, such that this series is convergent. A measure of this effect can be obtained from the flow rates for vibrating and non-vibrating conditions.

The rate of flow through a pipe is proportional to

$$\int_0^1 dx \int_0^{2\pi} xw d\varphi$$

so we see that further terms in the w series are required, for the ones that effect the flow are those where w is a function of x only. We find for the next term of the series that the part that is independent of φ is given by

$$w_2 = \frac{5x^4}{384} - \frac{13x^6}{576} + \frac{11x^8}{768} - \frac{x^{10}}{320} - \frac{19}{11520}$$

Using this term and neglecting further terms in the series gives the rate of flow through a pipe with a constant pressure gradient as

$$\frac{\pi R^2 W_0}{2}[1 - 1{\cdot}2 \times 10^{-3} K^2 \ldots\ldots]$$

When no vibration is present the rate of flow is given by $\frac{1}{2}\pi R^2 W_0$, but when vibration is present the rate of flow

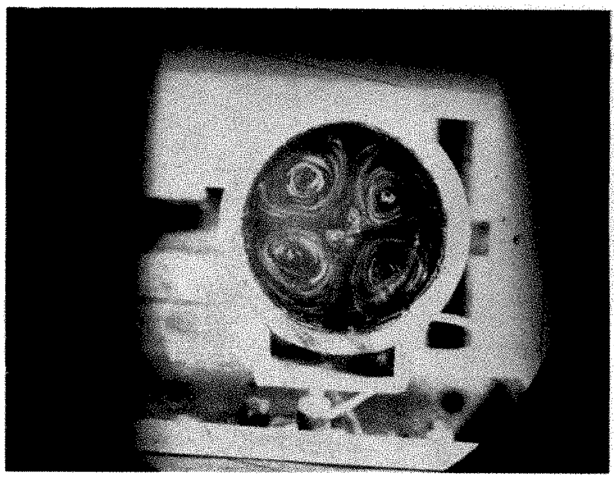

Fig. 2. Photograph of the secondary flow within a vibrating cylinder obtained with aluminium powder on the surface of water. The pipe diameter was 2·5 in. and the frequency of the weak vibration was 18 Hz. Subjecting the cylinder over a wide frequency range to additional vibrations and to intense vibrations gave very complex secondary flows, some of which appeared to be quite irregular. Very high streaming velocities were associated with some of the flows.

is reduced for the same applied pressure gradient. Consequently, the friction factor is increased and the effect depends on the value of K. It can be seen that for the equation to be valid then K must not be large. The equation gives then the effect of small vibrations on the laminar flow through a pipe.

The layer near the vibrating wall in which viscosity effects are large can be assumed to have a thickness $\sqrt{2\nu/n}$. This dimension must be small compared with the radius of the pipe if the analysis described is to be satisfactory.

In view of the limitations due to K and $\sqrt{2\nu/n}$ the theory would not be expected to describe the experimental investigation mentioned earlier[1], because K was of the order of 1,300–21,000 and $\sqrt{2\nu/n}$ was equivalent to a range of 6–28 per cent of the pipe radius.

The theory does indicate, however, that the friction factor will be increased in vibrating condition and when the vibrations are small this effect depends on K and

$$\frac{1}{R}\sqrt{\frac{2\nu}{n}}$$

THE SOLID STATE

Stress Dependence of Tensile Creep Rate in Carbons and Graphites

DESPITE the importance of carbons and graphites for very high temperature structural applications, very little is understood about the mechanisms of deformation and failure in these materials[1]. In principle, the stress dependence of the creep rate offers a simple method to obtain information on which of several possible deformation mechanisms operate at high temperatures. Using the empirical relationship $\dot{\varepsilon}=A\sigma^n$, where $\dot{\varepsilon}$ is the creep rate, σ is the stress and A is a proportionality constant, the stress exponent n is expected to equal one for Nabarro–Herring diffusion mass-transport creep; a much larger value of n, typically between 4 and 5, is expected for an edge dislocation climb mechanism such as occurs in many metals.

Stress exponent values of 5·5–8 have been reported for tensile creep of polycrystalline coke–pitch synthetic graphites[2-5]. This has been interpreted as evidence that climb of edge dislocation segments in crystallite tilt boundaries may be the rate-controlling mechanism[3]. Such graphites, however, usually show little or no reduction in area, which suggests that void growth (for example, by crack propagation or separation) is a principal source of macroscopic plastic strain and the deformation is highly localized in these materials. Recent investigations of the deformation behaviour of a high-density, stress-recrystallized coke-pitch graphite (ZTA) have supported this hypothesis[4-6]. Evidently, such "conventional" binder-filler synthetic graphites are not very suitable materials on which to investigate the deformation behaviour of graphite crystallites.

There are several other types of synthetic carbon and graphite in which void growth does not dominate the deformation. Pyrolytic carbons can be elongated more than 25 per cent parallel to the substrate plane at constant volume[1], and glassy (vitreous) carbons show considerable reduction in area in tensile creep (unpublished results), as does (reportedly) a commercially available fine-grained isotropic graphite ('Poco'). In such carbons, considerable crystallite deformation must occur, and a careful study of the macroscopic deformation behaviour should give information about the important fundamental mechanisms. An investigation of the stress dependence of the creep rate in pyrolytic and glassy carbons has been carried out and some results are reported here. Detailed accounts of these studies will be published elsewhere.

The pyrolytic carbon used was deposited at 2,200° C from methane by a commercial producer (Super Temp Corp.) and had a substrate-nucleated microstructure. Dog-bone type specimens of as-deposited material were deformed in tension parallel to the substrate plane under constant-load stresses of 5,000–30,000 lb./in.^{2}. Two grades of glassy carbon, *GC*-20 and *GC*-30, heat treated to temperatures of 2,000° C and 3,000° C, respectively, according to the manufacturer (Tokai Electrode Mfg. Co. Ltd.), were similarly tested at stresses ranging from 500–18,000 lb./in.^{2}. The creep tests were performed in a resistively heated graphite tube furnace in a helium atmosphere at temperatures of 2,500°–2,900° C. In common with most other carbons and graphites, neither pyrolytic nor glassy carbons exhibited a minimum or steady state creep rate. A stress-change technique was therefore developed to determine the stress dependence for a range of stresses in a single test on a single specimen. In all, nine glassy carbon and thirteen pyrolytic carbon tests were run.

In the earliest stages of the elongation of pyrolytic carbon, when layer straightening is the dominant process, $n\sim 4$ was found. In the range of elongation $1<\varepsilon<4$ per cent, however, n decreased rapidly to a value of about 1·5 where it remained until at least 26 per cent elongation was reached. After about 8 per cent elongation, the gauge section material was found to be well graphitized and very highly oriented with the layer planes aligned closely parallel to the stress axis[1]. No dependence of n on stress or temperature was observed. The creep activation energy was about 250 kcalories/mole, independent of elongation, in agreement with values found by Kotlensky[7] for pyrolytic carbon creep in the range $\varepsilon<10$ per cent and by Zukas and Green[5] for ZTA creep. This is an appropriate value for diffusion by a vacancy mechanism parallel to the layer planes[1]. It seems that in pyrolytic carbon, dislocation climb may be important initially, but after breakdown of the as-deposited structure has begun, a viscous process such as Nabarro–Herring creep predominates. The small excess of n over unity may be an experimental artefact, or may indicate simultaneous operation of a subsidiary deformation process with $1<n<3$.

The deformation behaviour of glassy carbon was quite different. The value of n increased approximately linearly with stress from a value near unity for $\sigma\leq 1,000$ lb./in.^{2} to ≥ 6 for $\sigma\geq 13,000$ lb./in.^{2}. No dependence of n on temperature or elongation (0–11 per cent) was observed, and the creep behaviour of the two grades was similar. A very high effective activation energy value of about 350 kcalories/mole was found in the medium stress range in which temperature dependence of the creep rate was investigated. Although Nabarro–Herring creep may be significant in glassy carbon at very low stresses, other mechanisms of uncertain nature must operate in the medium and high stress ranges. Because glassy carbon is a non-graphitizing carbon with small apparent crystallite size (~ 100 *A*) and a disordered structure, dislocation mechanisms seem unlikely. On the other hand, the appreciable reduction in area (nearly the constant volume value in *GC*-30) suggests that the deformation mechanism differs from that in conventional binder-filler synthetic graphites although the values of n are similar. More detailed knowledge of the structure of glassy carbons will probably be required before explanations of the interesting properties of these materials can be ventured with confidence.

Structure corresponding to the Ideal Composition $3Bi_2O_3.17Nb_2O_5$

As part of a study[1] of the structures of compounds in the Bi_2O_3–Nb_2O_5 binary system, we have determined the crystal structure of $3Bi_2O_3.17Nb_2O_5$, which we believe to be the ideal formula of the compound prepared by Roth and Waring[2] and referred to as $Bi_2O_3.6Nb_2O_5$.

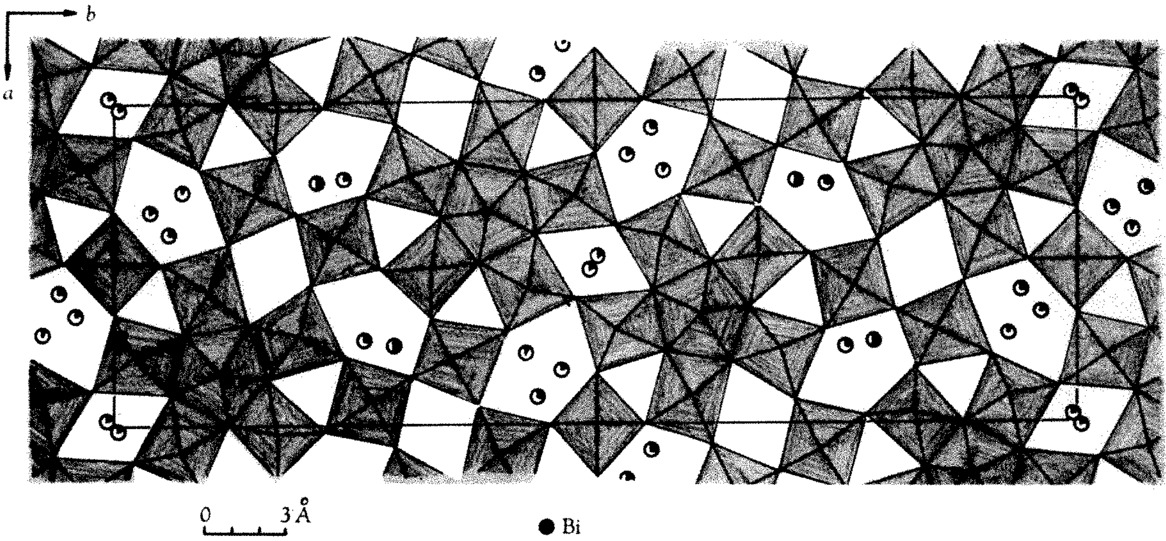

Fig. 1. The {001} projection of the structure of $3Bi_2O_3.17Nb_2O_5$ showing the $Me_{34}O_{94}$ matrix (shaded) and the occupancies of the bismuth sites.

The pale yellow plates of this material are orthorhombic with $a = 12{\cdot}516 \pm 0{\cdot}005$, $b = 37{\cdot}14 \pm 0{\cdot}02$, $c = 3{\cdot}922 \pm 0{\cdot}002$ Å, $U = 1828{\cdot}3$ Å^3. Using this unit cell we have been able to index fully the X-ray powder pattern published by Roth and Waring[2]. Single crystal photographs suggested that the structure was of the tetragonal bronze type[3] but with one cell edge tripled, and the intensities showed a remarkable similarity to those found by Sleight[4] for $Nb_{16}W_{18}O_{94}$.

The structure has been determined from some 1,300 independent reflexions, obtained with Cu–$K\alpha$ radiation and visually estimated. Least-squares refinement, in space group *Pba*2, has now reached $R = 0{\cdot}10$ and is being continued.

All atoms in $3Bi_2O_3.17Nb_2O_5$ are situated near two levels approximately $c/2$ apart. The structure is based on an $Me_{34}O_{94}$ matrix in which four of the twelve pentagonal tunnels are regular (in contrast with the other eight) and contain niobium atoms in pentagonal bipyramidal co-ordination. All the other niobium atoms have an octahedral co-ordination. The remaining eight pentagonal and six diamond-shaped tunnels, which are empty in $Nb_{16}W_{18}O_{94}$, contain all the bismuth atoms. We have found that these are statistically distributed among a number of possible sites, and have used the occupancy at each site as a parameter in the least-squares refinement. The resulting structure is shown schematically in Fig. 1.

The apparent chaos among the bismuth atoms is not unreasonable. The pentagonal and even the diamond-shaped tunnels are too large for the bismuth atom (ionic radius 0·96 Å) and, consequently, these atoms are located away from the centre of the hole. Furthermore, the bismuth atoms show a very strong tendency towards a one-sided four-fold co-ordination similar to that found, for example, in $BiSbO_4$ (ref. 5) and a number of other complex oxides and oxyhalides of bismuth[6-9]. This kind of co-ordination, a consequence of a lone pair of electrons, is more often associated with tervalent antimony[10,11] and is even found for arsenic[12]. The bismuth atoms could achieve this co-ordination at a number of sites. The bismuth occupancies of these sites are uneven (see Fig. 1) but add up to 5·7 ($2\sigma = 0{\cdot}2$) per unit cell, whereas 6 would be expected from the formula. It seems likely that the remaining 0·3 atoms are spread out thinly among some or all of the other possible sites. If, however, the true formula is $Bi_2O_3.6Nb_2O_5$, there would be $5\frac{5}{7}$ bismuth atoms per unit cell, but electrical neutrality would require the random removal of half an oxygen atom per unit cell.

It is difficult to reach a clear-cut decision between the two compositions, the difference between which is very slight (15·0 per cent Bi_2O_3, 85·0 per cent Nb_2O_5, $D_{\text{calc}} = 5{\cdot}37$ g cm^{-3} for 3 : 17, and 14·3 per cent Bi_2O_3, 85·7 per cent Nb_2O_5, $D_{\text{calc}} = 5{\cdot}30$ g cm^{-3} for 1 : 6). We consider, however, that $3Bi_2O_3.17Nb_2O_5$ represents the ideal structural formula.

Nuclear Hyperfine Interactions in Diatomic Molecules and the Ground State of VO

THE identification of the ground states of the diatomic oxides of the transition metals presents interesting experimental[1] and theoretical[2] problems, and the VO molecule is one example. Analogy with TaO suggests[3] that the lowest state should be $\sigma^2\delta\ {}^2\Delta$, but theoretical calculations[4] indicate that it is $\sigma\delta^2\ {}^4\Sigma^-$. This is supported by unpublished observations of P. H. Kasai and W. Weltner of the electron spin resonance spectrum of matrix isolated VO. A rotational analysis[5] of several bands of the green system ($\nu_{00} = 17{,}419$ cm^{-1}) led to values of the internuclear distances in the two states, but the transition was not identified: it was suggested that it might be spin-forbidden.

We now report preliminary results of the rotational analysis of bands of the green and red[6,7] (ν_{00}, $F_4 = 12{,}707$ cm^{-1}) systems. We have found that both systems may be observed in absorption at $t \sim 1{,}650°$ C in a carbon tube furnace with short paths: both systems are therefore most probably allowed. The bands of the green system consist of the four branches analysed correctly by Lagerqvist and Selin[5] as R and P branches and, in addition, four broad line branches, two R and two P. The lines of these branches are about 0·4 cm^{-1} wide, and the widths are independent of N, at least for $15 \leqslant N \leqslant 70$. The energy levels in all states are determined by an integral quantum number N rather than half integral J, so that the transition is ${}^4\Sigma$ (case b)–${}^4\Sigma$ (case b), with four R and four P branches.

Analysis of the red system is incomplete, but parts of the two shortest wavelength components of the 1–0 and 0–0 bands have been analysed. These bands show many branches, broad and sharp, and the upper state energy levels are determined by a half integral quantum number J. Thus the upper state is a case a state. Lower state combination differences are found in excellent agreement with those observed in the green bands. In the shortest wavelength components of the 0–0 and 1–0 bands, six sharp branches have been analysed which may be assigned as the ${}^TR_{42}$, ${}^SR_{43}$, ${}^SQ_{42}$, ${}^RQ_{43}$, ${}^RP_{42}$, and ${}^QP_{43}$ branches in ${}^4\Pi_{5/2}$–$X{}^4\Sigma^-$.

Line widths in the green bands are unaffected by the many upper state perturbations: this fact, together with the observation of broad lines in the red system, suggests that the cause of the broadening, or unresolved splitting, is to be sought in the behaviour of two of the four components of the ${}^4\Sigma^-$ ground state. Analysis of the red bands shows that the F_2'' ($J = N + \frac{1}{2}$) and F_3'' ($J = N - \frac{1}{2}$) components are sharp and it is therefore the F_1'' ($J = N + \frac{3}{2}$) and F_4'' ($J = N - \frac{3}{2}$) components which are broadened, by a factor of about three.

The theoretical calculations[4] suggest that the σ electron in the $\sigma\delta^2$ ground configuration is predominantly $4s\sigma$ on V. The splitting of the levels may be understood on the basis of a magnetic hyperfine interaction of this electron with the ^{51}V nucleus of spin $\frac{7}{2}$ and magnetic moment 5·14 nm. The δ electrons will not contribute significantly to the hyperfine energy which may be written[8]

$$W_{hfs} \simeq b\,\bar{I}.\bar{s},$$

with

$$b = \frac{2\,\mu_0\mu_I}{I}\left[\frac{8\pi}{3}\,\psi^2(0) - \frac{3\cos^2\theta - 1}{2r^3}\right]_{av} :$$

for a near spherical distribution of charge, only the term in $\psi^2(0)$ will be important. If the magnetic interaction is weak compared with the coupling of the other angular momenta the overall coupling will be $b_{\beta J}$ and the hyperfine energy will be given by

$$W_{hfs} = \frac{b}{3}\,\frac{[J(J+1) - N(N+1) + S(S+1)]}{2\,J(J+1)}\;\bar{I}.\bar{J}$$

where

$$\bar{I}.\bar{J} = \tfrac{1}{2}\,[F(F+1) - J(J+1) - I(I+1)].$$

If this hyperfine splitting is not resolved, the line width will be given by $(W_{F\max} - W_{F\min})$, where $F_{\max} = J + I$ and $F_{\min} = J - I$, as in BiO (ref. 9). This leads to calculated widths of lines originating from F_1'' and F_4'' which are about three times those arising from F_2'' and F_3'' for $N \gtrsim 15$ when the widths become constant, in good agreement with the observed spectrum.

We conclude that the ground state of VO is $\sigma\delta^2\ {}^4\Sigma^-$, and that this state provides a further example of a situation in which nuclear hyperfine splittings contribute significantly to the appearance of the optical spectra[10].

Electron Spin Resonance Study of Nitroxide Radicals from Diethylhydroxylamine, Dioctylhydroxylamine and *N*-Hydroxypyrrolidine

WE present here the results of an electron spin resonance investigation of the free radicals formed from diethylhydroxylamine, dioctylhydroxylamine and N-hydroxypyrrolidine. Dioctylhydroxylamine was prepared by the method of Harris and Olcott[1]. Diethylhydroxylamine was obtained from Pennsalt Chemicals (85 per cent and 100 per cent) and from K and K Laboratories (85 per cent). N-Hydroxypyrrolidine was prepared by the method Wolfenstein[2] used for N-hydroxypiperidine and by the method described by Blout[3].

Purity of compounds was determined by thin-layer chromatography using solvent systems of acetone, methanol and acetone : methanol 1 : 1 (v/v). The K and K diethylhydroxylamine (85 per cent) gave three spots and the 100 per cent material gave two spots. N-Hydroxypyrrolidine also gave two spots. As a result of these tests, the samples were purified as oxalate derivatives and the hydroxylamine was recovered by treatment with liquid ammonia. When standard solutions of the purified materials were spotted immediately after release from the oxalate salt, each gave only a single spot.

The tertiary butylhydroperoxide used to oxidize the hydroxylamines was a product of K and K Laboratories. The molar ratios of hydroperoxide to hydroxylamine were 1 : 1 or 2 : 1. Spectra were obtained with a Varian E-3 EPR spectrometer.

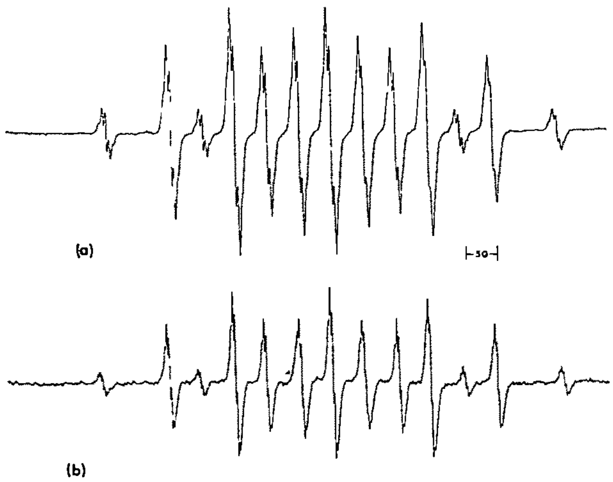

Fig 1 Room temperature electron spin resonance spectra for (*a*) dioctylhydroxylamine and (*b*) diethylhydroxylamine showing hyperfine coupling to β and γ protons In (*a*) there are four equivalent γ protons giving a hf splitting of five lines with intensity ratios 1 4 6 4 1 In (*b*) there are six equivalent γ protons giving seven lines with intensity ratios 1 6 15 20 15 6 1

The electron spin resonance spectra show that the free radicals are nitroxides resulting from abstraction of hydrogen from the hydroxyl group Similar spectra have been obtained by others from related amines oxidized to nitroxide free radicals[4–6] The three compounds gave similar electron spin resonance spectra consisting of fifteen lines resulting from coupling to nitrogen and to the four equivalent protons β to the nitrogen The differences in the observed spectra result from different values for the nitrogen and β proton coupling constants In conditions of high resolution, coupling to γ protons could be resolved for diethyl- and dioctyl-hydroxylamines purged of oxygen (Fig 1) This coupling has not so far been detected For *N*-hydroxypyrrolidine, however, the γ splitting, while observable, could not be resolved The results are summarized in Table 1

Table 1 HYPERFINE COUPLING CONSTANTS FOR THE NITROXIDE RADICALS OF DIETHYLHYDROXYLAMINE, DIOCTYLHYDROXYLAMINE AND *N*-HYDROXYPYRROLIDINE

	Coupling constants (gauss)		
Radical	A_N	A_N^{β}	A_H^{γ}
Diethylhydroxylamine  $CH_3—CH_2—\underset{\overset{\mid}{O}}{N}—CH_2—CH_3$	15 9	10 9	0 33
Dioctylhydroxylamine  $CH_3(CH_2)_5CH_2—CH_2—\underset{\overset{\mid}{O}}{N}—CH_2—CH_2(CH_2)_5CH_3$	15 4	10 2	0 50
N-Hydroxypyrrolidine 	15 0	19 2	~0 3

The commercial samples of diethylhydroxylamine were frequently found to exhibit nitroxide electron spin resonance spectra as received and the nitroxide radical concentration in these samples was observed to vary with exposure to ambient light This suggested that nitroxide free radicals are produced in hydroxylamines photochemically To investigate this possibility, samples, both as received and after purification as the oxalate, were prepared in quartz sample tubes with and without oxygen and illuminated in the cavity by a high intensity, *AH*-6 mercury lamp The response of these samples to light was found to be quite different before and after purification and to be independent of oxygen content

For the unpurified samples, the light produced a marked increase in the electron spin resonance signal which decayed when the lamp was extinguished The light also increased the yield of free radicals in samples to which peroxide had been added When wavelengths below 280 mμ were filtered out, the *AH*-6 lamp still produced a substantial electron spin resonance signal, indicating that long wavelength ultraviolet and visible light readily causes these effects Attempts to establish the rates of growth and decay of the free radicals against light intensity were unsuccessful because reproducible results could not be obtained

The purified samples, on the other hand, showed quite different behaviour Before illumination, the pure samples exhibited little or no initial nitroxide electron spin resonance signals, and illumination with wavelengths greater than 280 mμ produced no detectable electron spin resonance spectra in these samples The effect of short wavelength ultraviolet was investigated by irradiating the purified samples for 5 min at 254 mμ by means of two 15 W germicidal ultraviolet lamps The samples were immediately placed in the cavity and a significant nitroxide signal was observed which decayed slowly on standing Kinetic data could not be obtained at this wavelength because the output from these lamps could not be directed into the cavity

Ultraviolet spectra of the hydroxylamines were in accord with these findings The purified hydroxylamines showed no characteristic absorption above 220 mμ whereas the unpurified samples showed weak absorption bands at 240 mμ and 335 mμ After the purified samples had been irradiated at 254 mμ, a band appeared at 240 mμ This band increased with irradiation and is probably caused by the formation of oxidation products, such as nitroxide radicals which show absorbance at 240 mμ

These results show that nitroxide radicals can be produced directly from hydroxylamines by irradiation at 254 mμ, but not by light of longer wavelength The production of nitroxide radicals by long wavelength ultraviolet and visible light in unpurified or commercial samples is attributed to small amounts of light-sensitive impurities present in these materials Although these impurities have not been identified, traces of peroxides, for example, could cause these effects and account for the non-reproducible kinetic results

We thank Dr Barbara Beck for preparing some of the purified samples This work was supported in part by a grant from the National Institutes of Health, US Public Health Service

Molecular Interactions between Tryptophan and Nucleic Acid Components in Frozen Aqueous Solutions

NUCLEIC acids exhibit specific interactions with nucleoproteins and enzymes at different stages of the replication and expression of the cellular genome, and it seemed worthwhile to investigate the nature of such molecular interactions between nucleic acid components and amino-acids. This article deals with a study of complexes of tryptophan and nucleosides in frozen aqueous solutions We have already shown that, in frozen aqueous solutions, nucleic acid derivatives and aromatic amino-acids form aggregates[1,2] Thus freezing aqueous solutions may induce the formation of molecular complexes as a result of a close contact between two kinds of molecules

We have used two techniques in this investigation Emission measurements were made at the temperature of liquid nitrogen (77° K) with an Aminco–Bowman spectrophotofluorimeter Aqueous solutions were frozen in quartz tubes of 2 mm inner diameter Absorption spectra were deduced from reflectance spectra (the opacity of the frozen samples precludes the use of standard absorption spectroscopy) Reflectance spectra were obtained with a Cary 14 spectrophotometer equipped with the total diffuse reflectance accessory adapted for low temperature measurements (our unpublished work). All spectra were recorded at 253° K, for no modification was observed between 253° and 77° K

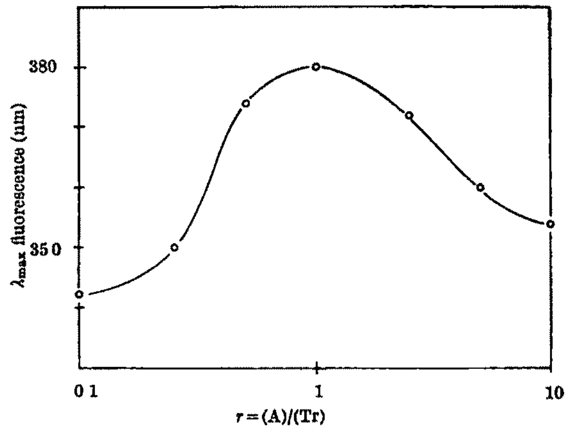

Fig 1 Variation of the fluorescence λ_{max} of tryptophan (Tr) and adenosine (A) mixtures in frozen aqueous solutions (77° K) as a function of the concentration ratio r

Table 1 FLUORESCENCE λ_{max} OF TRYPTOPHAN, NUCLEOSIDES AND EQUIMOLECULAR MIXTURES OF TRYPTOPHAN AND NUCLEOSIDES IN FROZEN AQUEOUS SOLUTIONS AT 77° K ($c=10^{-3}$ M)

Fluorescence λ_{max} (aggregates, nm)		Fluorescence λ_{max} of equimolecular mixtures with tryptophan (nm)
340	Tryptophan	
345	Guanosine	360
340	Adenosine	380
340	Cytidine	420
330	Thymidine	420
—	Uridine	420

In frozen aqueous solutions at 77° K, the fluorescence spectrum of 10^{-3} M equimolar mixtures of tryptophan and nucleosides is red-shifted as compared with that of the separated components (Table 1) The red-shift is larger with pyrimidine than with purine nucleosides, but is not modified when the concentration of both components of the mixture increases from 10^{-4} to 10^{-2} M When the ratio, r, of the nucleoside and tryptophan concentrations differs from unity, the fluorescence spectrum is the superposition of the emission from the component in excess and from the complex The apparent λ_{max} of the fluorescence spectrum goes through a maximum for $r \simeq 1$ (Fig 1), thus indicating that a 1 1 complex is probably formed The phosphorescence of the molecular mixtures is very weak, and its spectrum and decay characteristics are very close to those observed in pure tryptophan solutions in the same conditions.

The addition of increasing amounts of tryptophan to a 10^{-3} M solution of cytidine (or uridine) produces, after freezing, a new absorption band on the long-wavelength side of the component spectra (Fig 2*b*) The variation of the intensity of this band at 310 nm with tryptophan concentration (Fig 2*a*) confirms that a one to one complex is formed

The formation of aggregates in frozen aqueous solutions is inhibited by addition of small amounts of organic solvents like ethanol or propylene glycol[1-4] In such conditions, the fluorescence and absorption bands, characteristic of the complex, are not observed It must also be noted that no complex is formed in fluid solution at 293° K The appearance in mixtures of electronic transitions different from those of the components has been ascribed to molecular complexes in which charge-transfer forces play an important part[5] Indole derivatives (including tryptophan) form molecular complexes with biologically important compounds[6] Charge-transfer complexes of indoles with several electron-acceptor molecules have also been reported[7] The energy values of the lowest empty molecular orbitals of nucleic acid bases, calculated in the SCF–LCAO–MO approximation, suggest that pyrimidines are better electron acceptors than purines[8] In agreement

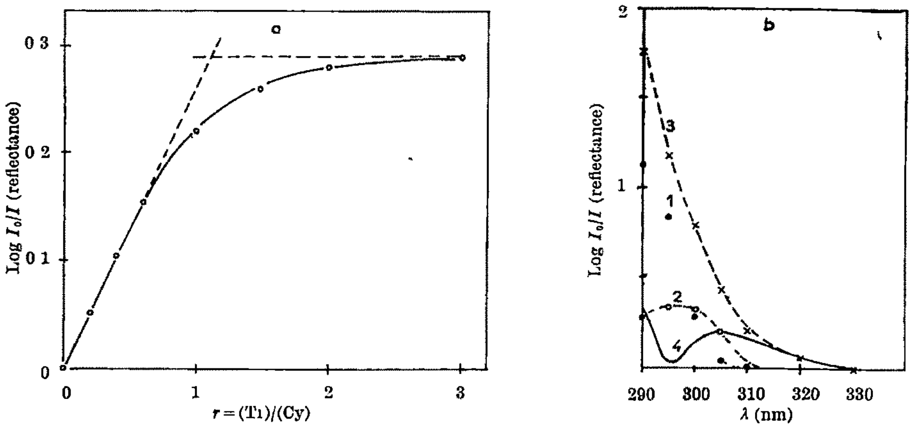

Fig 2 *a*, Variation of the band intensity at 310 nm in cytidine (Cy) and tryptophan (Tr) frozen aqueous mixtures when the concentration of tryptophan increases from 0 to 3×10^{-3} M I and I_0 are the light intensities reflected by the frozen sample with and without solute molecules, respectively {Cy}$=10^{-3}$ M *b*, Long wavelength side of the apparent absorption spectra deduced from the reflectance spectra of 10^{-3} M frozen aqueous solutions of (1) cytidine ( ), (2) tryptophan (– – –), and (3) their equimolecular mixture (– – –) Spectrum (4) (——) is the difference between (3) and the sum (1)+(2)

with this, the transition energies corresponding to their complexes with tryptophan are lower for pyrimidine than for purine nucleosides We did not observe any new electronic transitions when nucleosides were mixed with tyrosine or phenylalanine, which are poorer electron donors than tryptophan Thus charge-transfer forces are probably involved in stabilizing the ground electronic states of nucleoside–tryptophan complexes

Such molecular complexes may be important in the interactions between nucleic acids and enzymes This work is now being extended to tryptophan derivatives, oligopeptides and oligonucleotides

Tryptophan Emission from Trypsin and Polymer Films

THE sensitivity of the fluorescence and phosphorescence of the aromatic amino-acids to variations in their immediate environment[1–6] provides one of the few tools for probing the interior of proteins in a wide range of conditions The present studies show that for the interval 200°–300° K the phosphorescence from the tryptophans in the enzyme trypsin more closely resembles that from tryptophan in polyvinyl alcohol films (PVA) than that from tryptophan in aqueous systems This conclusion is based on comparisons of the wavelengths at which the maxima for fluorescence and phosphorescence are observed as well as the quantum yields for emission in the various systems Two of the most significant observations leading to this conclusion are that · (*a*) phosphorescence is observed at room temperature from tryptophan in either PVA or trypsin, and (*b*) temperature has many similar effects on the phosphorescence from tryptophan in PVA and from trypsin In the range 77°–170° K, however, the trypsin interior seems to be less "rigid" than either a water or PVA matrix

Previous work has shown that, even though the radiative quantum yield (fluorescence plus phosphorescence) of aromatic amino-acids in frozen aqueous media (77° K) remains essentially 1 0, the ratio of phosphorescence to fluorescence (P/F) varies markedly with *p*H and added solutes[6]. Because a variety of added solutes produce approximately comparable changes, these effects must primarily reflect alterations in the crystalline structure and rigidity, or both, of the surrounding matrix, some of the observed effects, it seems, can, however, also be produced by direct interaction of the added solute molecules with the aromatic amino-acids Experiments have thus been undertaken in our laboratory using simplified model systems in which the aromatic amino-acids are embedded in polymers containing hydroxyl, amino or carboxyl side-chains to test the effects of these groups on the aromatic residues in relatively fixed spatial environments such as are thought to comprise the interior of proteins

For the present studies, thin films of tryptophan in PVA were prepared such that the amino-acid molecules should be sufficiently separated so as to minimize self-quenching The water was evaporated from 1 mm layers of 10 per cent PVA solutions containing 1×10^{-4} M tryptophan (final thickness was about 0 1 mm and average separation corresponded to that of molecules in a 10^{-3} M solution). Thin layers of dried trypsin were prepared by evaporating solutions containing 1 mg/ml. trypsin dissolved in distilled water which had been spread on to 'Visking' dialysis membrane

Table 1 EMISSION CHARACTERISTICS OF TRYPTOPHAN IN DIFFERENT ENVIRONMENTS

* Temperature intensity curve suggests that the long τ_{37} component disappears at 1–2 s, leaving only the short λ component

The intensity of emission arising from these preparations on excitation with 270 nm wavelength light was compared with that from a 1 mm layer of 1×10^{-4} M tryptophan dissolved in water (in order to observe emission from comparable numbers of tryptophan molecules) The determinations of fluorescence at room temperature were made in a "front face" apparatus[7] at 45° to the incident light Corrections for light scattering were made according to the method previously described[8] and the effect of polarization on the emission from these films was minimized by techniques to be discussed elsewhere (submitted for publication) The behaviour of fluorescence and phosphorescence as a function of temperature (down to 77° K) was studied in a 'Dewar' cooled by liquid nitrogen with the films mounted slightly off 45° to the exciting and emitting monochromators to minimize surface reflectance The temperature was monitored with an iron-constantan thermocouple

The feeble phosphorescence persisting at room temperature is normally obscured by scattered light and can also be confused with emission from the PVA A rotating shutter was used to minimize the scattered light Furthermore, it was established that the emission at room temperature had fine structure characteristic of tryptophan phosphorescence and also had an excitation spectrum corresponding to the absorption spectrum of tryptophan By contrast, the excitation spectrum of emission from PVA alone extends to considerably longer wavelengths

The values of λ_F and λ_P for the various preparations vary by only 10 nm at 77° K (Table 1) From previous results, it was concluded that frozen aqueous matrices are so rigid at this temperature that they are incapable of effective collisional interaction with the excited amino-acids; the temperature studies discussed here indicate, however, that this may not be so for tryptophan in trypsin There is clearly a slight increase in the interactions between tryptophan and PVA at room temperature as the fluorescence maximum is shifted 5 nm toward lower energies, these interactions must, however, be much less than those in the aqueous solutions because in the latter there is a red-shift of 25 nm on warming This difference in the extent of interaction at room temperature is further reflected in the observation that the fluorescence quantum yield in PVA is 0 3–0 56 compared with 0 2 in water† It is difficult to ascribe unequivocally the larger (compared with glucose–water) values of P/F in the PVA films to enhanced intersystem crossing alone, because in both

---

† The variation in the Q_P values in PVA is probably not simple variance because eight determinations clustered around either 0 3 or 0 56 Investigations are now under way to determine whether this reflects hygroscopic behaviour of the polymer which changes either its rigidity or the mutual tryptophan–PVA orientation differences observed between yields in ices of distilled water and of glucose have been attributed previously to alterations in the structure of the ice[6]

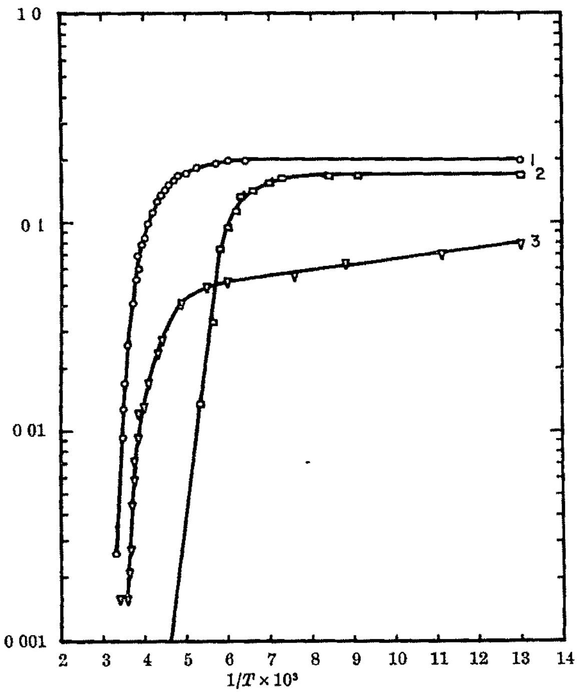

Fig 1 Arrhenius plots of phosphorescence quantum yields as a function of temperature for (1) tryptophan in PVA film, (2) tryptophan in 0 55 per cent glucose–H_2O, (3) trypsin film

systems the total quantum yield of tryptophan is not unity even at 77° K

Comparison of the temperature plots in Fig 1 indicates that both the onset and extent of quenching of phosphorescence in the PVA films are shifted toward higher temperatures relative to the data for glucose–water In fact, this shift is so pronounced that tryptophan phosphorescence persists even up to room temperature in some of the PVA films the tryptophan phosphorescence can be distinguished from the weak emission from PVA itself (having a single peak), by its fine structure with a maximum at 445 nm and secondary peaks at 425 and 475 nm as well as by differences in their excitation spectra Because the slopes of the Arrhenius plots are the same, presumably the interactions causing quenching are the same or have the same activation energies in the two systems, but the number of unperturbed molecules differs significantly

It is evident in Fig 1 that there is a great similarity between the effects of temperature on emission in tryptophan in the PVA films and in trypsin This includes the positions of the break point (c 170° K) and the almost identical slopes in the range 200°–300° K There are differences, however, when the samples are cooled from 170° K to 77° K for example, phosphorescence intensity may remain almost constant in some PVA preparations (Fig 1) and increase up to about 30 per cent in other PVA preparations, whereas there is always an increase of about 30 per cent in trypsin In those PVA preparations which exhibit an increase in intensity in the low temperature range, the high temperature slope is displaced slightly towards lower temperatures so that phosphorescence may disappear somewhat below room temperature This presumably indicates a less rigidly bonded PVA structure which could arise from differences in configuration, molecular weight or water content The overall similarities in the emission behaviour of trypsin and of tryptophan in PVA indicate, however, that the rigidity of the two systems with consequent probability of quenching interactions is very similar Furthermore, at least some of the entities in the interior of trypsin near some or all of the tryptophans are not completely "frozen in" even at 77° K, whereas it is possible to vary the extent of this "freezing in" in the PVA matrix

BIOCHEMISTRY

Inhibition by Drugs of the Accumulation *in vitro* of 5-Hydroxytryptamine in Guinea-pig Vas Deferens

AFTER an injection of ^{14}C-5-hydroxytryptophan, autoradiographic grains were found to accumulate in the sympathetic neurones of the pineal gland and vas deferens[1] These observations suggested that the sympathetic nerves of these organs might take up or retain 5-hydroxytryptamine Subsequent work has shown that 5-hydroxytryptamine can accumulate in the guinea-pig vas deferens *in vitro* by an active transport process[2] Subcellular distribution studies also indicated that the site of accumulation of the 5-hydroxytryptamine is the storage vesicle present in the sympathetic neurone[2] Certain drugs such as imipramine[3] and cocaine[4] are potent inhibitors of the uptake of noradrenaline into sympathetic neurones, and these drugs also block the uptake of 5-hydroxytryptamine in platelets[5] and some tissues in the rat[6] Subsequent work has shown that the site of blockade of noradrenaline uptake is the neuronal membrane[7] These observations prompted us to investigate the ability of these drugs to block the uptake in the vas deferens of 5-hydroxytryptamine labelled with carbon-14

The vas deferens were obtained from guinea-pigs weighing 250–300 g The animals were killed by a blow on the head, bled and the vas deferens rapidly removed and chilled They were cut into segments weighing approximately 20 mg and four such segments were incubated for 30 min at 37° C in 4 ml of Krebs–Ringer phosphate containing 0 4 μCi of ^{14}C-5-hydroxytryptamine (specific activity 40 mCi/mmole)

On removal from the medium they were washed, blotted and homogenized separately in 0 4 N perchloric acid and the homogenate was centrifuged at 15,000*g* for 15 min A 1 ml sample of the supernatant fluid was adjusted to *p*H 10 with sodium hydroxide and 1 5 ml of 0 5 M borate buffer *p*H 10 and the 5-hydroxytryptamine was extracted into 6 ml of isoamyl alcohol by shaking for 5 min After centrifugation a 4 ml sample of the isoamyl alcohol extract was transferred to a counting vial containing 4 ml of ethanol and 10 ml of phosphor 10 mg of ascorbic acid was added to a second 1 ml sample of the supernatant and the *p*H was adjusted to 1 0 by the addition of concentrated hydrochloric acid The 5-HIAA was extracted into 5 ml of diethyl ether by shaking for 3 min After standing, a 4 5 ml sample of the ether phase was shaken for 3 min with 1 ml of 0 5 M phosphate buffer *p*H 7 9 An 0 4 ml sample of the buffer extract was added to the phosphor containing 5 ml of a mixture of ethanol methanol (3 1) These methods had been shown to be specific by paper chromatography

Guinea-pig vas deferens incubated with ^{14}C-5-hydroxytryptamine (2 5 × 10^{-6} M) for 30 min was shown to give

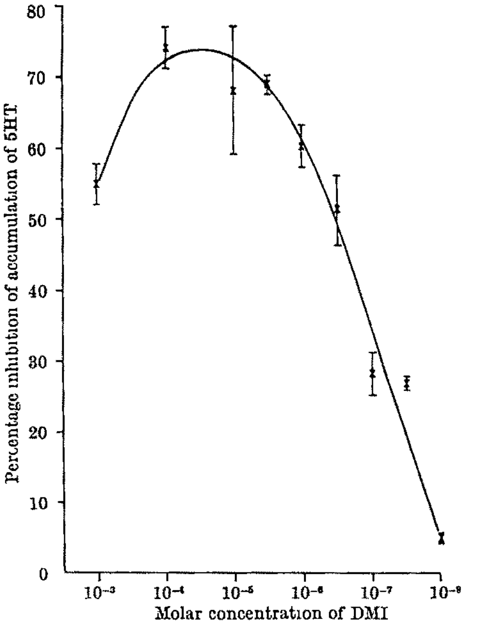

Fig 1 Inhibition of uptake of ^{14}C-5-hydroxytryptamine (5HT) in guinea-pig vas deferens by desmethylimipramine (DMI) Each group contained vas deferens from four guinea-pigs Results are expressed as mean ±*S E M*

a two-fold increase in concentration in the tissue above the medium In addition, approximately equimolar amounts of the deaminated metabolite 5-HIAA were also present in the vas deferens In the presence of cocaine 1×10^{-4} M and imipramine 1×10^{-4} M, this accumulation was reduced to 22 per cent and 38 per cent of controls, respectively The conversion to 5-HIAA, however, was unchanged at these concentrations Desmethylimipramine was found to inhibit uptake in concentrations as low as 3×10^{-8} M From 3×10^{-5} M to 1×10^{-8} M the inhibition was linear with the logarithm of the concentration for the drug (Fig 1) With very high concentrations of desmethylimipramine (10^{-3} M) the formation of 5-HIAA was inhibited, but at lower concentrations the formation was unaffected

In a previous study, it was shown that the antidepressant drug imipramine and a variety of structurally related compounds blocked the uptake of tritiated noradrenaline into the intact brain[8] It was found that those drugs with antidepressant activity blocked the uptake into brain, but those structurally related drugs which were not antidepressant did not A similar study was undertaken to determine the effect of tricyclic compounds with and without antidepressant activity on the blockade of accumulation of 5-hydroxytryptamine by the guinea-pig vas deferens For this study, the concentrations were chosen at which desmethylimipramine produced approximately 50 per cent inhibition (5×10^{-7} M). There seemed to be a consistent relationship between the ability of tricyclic compounds to block the accumulation of 5-hydroxytryptamine in vas deferens and their antidepressant activity (Table 1) There was no change in the formation of 5-HIAA

Table 1 INHIBITION OF ACCUMULATION OF ^{14}C-5-HYDROXYTRYPTAMINE IN GUINEA-PIG VAS DEFERENS BY ANTIDEPRESSANT DRUGS

Drug	Inhibition of accumulation (%)	Clinical activity†

† Clinical observations by experienced psychiatrists carried out on a limited number of patients Details of the tests can be obtained from Dr Murray Weiner, Geigy Research Laboratories, Yonkers, New York

The process of biogenic amine uptake by the vas deferens seems to be more closely related to the brain than other peripheral tissues The uptake of noradrenaline[8] in the brain and 5-hydroxytryptamine in the vas deferens is blocked by imipramine and its clinically active congeners Furthermore, chlorpromazine inhibits the uptake of biogenic amines in peripheral tissues[3] but not in brain[8] or vas deferens In view of these observations the vas deferens could serve as a useful model for brain biogenic amine containing neurones in studying the effect of certain drugs on amine uptake processes

Concentrations of Metabolic Intermediates in Kidneys of Rats with Metabolic Acidosis

GOODMAN *et al* [1] have shown that there is enhanced renal gluconeogenesis in the rat with chronic metabolic acidosis The enhancement of renal gluconeogenesis with glutamine, glutamate, α-ketoglutarate and oxaloacetate, but not with fructose or glycerol as substrates, led to the tentative conclusions that in acidosis there is acceleration of one of the steps in the gluconeogenesis pathway distal to oxaloacetate The results presented here represent an attempt to define that step

Two types of experiments were carried out on locally bred albino rats weighing 200–300 g Five or six rats were used in each experiment They were deprived of all solid food during the experiment but allowed free access to 0 2 per cent sodium chloride in water The control rats were fed 10 ml of 20 per cent dextrose in water by stomach tube every 12 h, while the experimental rats were fed 10 ml of 20 per cent dextrose containing 200 mM ammonium chloride In a total of six such experiments, fourteen control and sixteen experimental rats were used

In the second type of experiment, rats were also deprived of solid food and allowed free access to 0 2 per cent sodium chloride, and both control and experimental rats were fed 10 ml of 20 per cent dextrose in water by tube every 12 h As an acidifying agent, acetazoleamide ('Diamox') was injected intraperitoneally in a dose of 75 mg/kg every 12 h The controls were injected with an equal volume of saline Fourteen control and eighteen experimental rats were used in six experiments All experiments were concluded after 48 h

Rats were anaesthetized with intraperitoneal pentobarbital 50 mg/kg, both kidneys were then rapidly

removed, dropped into a stainless steel mortar containing liquid air and squashed flat immediately There was never a delay of more than 5 s between removal of kidneys and complete freezing Tissue from each rat was processed separately The tissue was ground to a powder under liquid air, and then transferred frozen to weighed 'Duall' all-glass homogenizers containing ice cold 6 per cent perchloric acid The further handling of the tissue and the enzymatic measurements of the metabolic intermediates, except citrate, were by standard methods[2] Citrate was measured with the enzyme citrate-lyase as described by Moellering and Gruber[3]

The results are shown in Table 1 With both acidifying agents, there were significant reductions in the concentrations of citrate, α-ketoglutarate and malate as compared with controls There was no statistically significant change in the concentrations of pyruvate or aspartate In four of the six experiments with ammonium chloride and four of the six with acetazoleamide, however, there was a fall in aspartate in the experimental rats There was consistently a significant rise in phosphoenol-pyruvate The fact that identical results are obtained with both ammonium chloride and acetazoleamide implies that the effect resulted from the acidosis rather than from the agent which produced it Similar protocols have previously been shown to cause metabolic acidosis[1,4] in rats

The first important site of possible control in the gluconeogenetic pathway involves carboxylation of pyruvate to oxaloacetate by the enzyme pyruvate carboxylase with further conversion of oxaloacetate to phosphoenolpyruvate by the enzyme phosphoenol pyruvate carboxykinase (PEPCK) (ref 5) Aspartate was measured in these experiments as a guide to the concentrations of oxaloacetate, which usually exists in very small concentrations in tissues The fact that the concentration of aspartate was not significantly changed or at least fell in most experiments would indicate that there was no change, or possibly a reduction, in concentrations of oxaloacetate The rise of phosphoenol-pyruvate indicates therefore an increased activity of PEPCK This supports the conclusion of Goodman *et al* that the acceleration of gluconeogenesis is at a site distal to oxaloacetate

In chronic metabolic acidosis with an increased production of ammonia, there is increased activity of the enzymes glutaminase 1 and glutamine transaminase[6,7] The product of the former reaction is glutamate and of the latter α-ketoglutaramate and subsequently α-ketoglutarate α-Ketoglutarate is also the deamination product of glutamate It might therefore be expected that there would be a rise in the concentrations of these two intermediates In fact, a reduction in glutamate concentrations in similar conditions has already been reported[4] and in these experiments there is a fall also in α-ketoglutarate The decreased concentrations of glutamate have been shown to be important because glutamate itself inhibits the enzyme glutaminase 1 (ref 8). This is another example of feed-back inhibition It is possible that α-ketoglutarate acts similarly on the glutamine transaminase It is very likely that in metabolic acidosis the enhanced gluconeogenesis which occurs serves to remove products such as glutamate and α-ketoglutarate and thereby allows the necessary increased production of ammonia The data presented here indicate that the site of enhancement of the gluconeogenesis pathway in acidosis lies at the step between oxaloacetate and phosphoenol pyruvate, mediated by the enzyme PEPCK The reduction in concentrations of citrate and malate is also indicative of increased diversion of oxaloacetate along the gluconeogenesis pathway

Regulatory Effect of N⁶-Benzyladenine and Pseudothymine (6-Methyluracyl) on the Synthesis of Nucleic Acids

CYTOKININS have been shown to have a hormone-like regulatory effect on the synthesis of DNA-dependent RNA (refs 1 and 2) McCalla *et al*[3] demonstrated a very low level of incorporation of benzyladenine into the insoluble RNA fraction We confirmed these findings and showed (unpublished work of G Matolcsy, K. Bojthe and B I Pozsár) that benzyladenine was incorporated without degradation Fox[4,5] showed that labelled benzyladenine accumulates to a large extent in the soluble RNA fraction, and Letham and Ralph[6] hydrolysed the isolated RNA from plant tissues, which liberated basic compounds with cytokinin-like activity We have examined the effect of several pyrimidine base-analogues on nucleic acid metabolism The synthesis of RNA was increased most by pseudothymine (6-methyluracyl) This compound is a structural isomer of thymine and can be regarded as a potential antagonist of both uracyl and thymine Its biological effect has been little studied, however[7]. This finding led us to compare this compound with 6-benzyladenine, known to be a substance with the biological activity of a cytokinin.

The method of Whitehead *et al*[8] was used to prepare both 2′-^{14}C- and 8-^{14}C-benzyladenine Labelled 2-^{14}C-6-methyluracyl was prepared by the method of Donleavy and Kise[9] Insoluble RNA was isolated from the leaf tissues using a modification by Fletcher and Osborne[10] of the Schmidt and Thannhauser[11] method

Neither the N⁶-benzyladenines nor ^{14}C-pseudothymine (^{14}C-2-6-methyluracil, unpublished work of G Matolcsy, I Pintér and B I Pozsár) incorporated into the insoluble RNA as well as adenine and uracil, respectively (Table 1) After the benzyladenine treatment, the

8-^{14}C-Adenine	12,290	187	23,630	19,590	312	37,670	159
2-^{14}C-Uracyl	10,440	163	20,070	13,250	206	25,480	127

In 100 mg fresh weight of leaves was 0 52 mg of ribose

incorporation of the labelled adenine was nearly as great as that of the orotic acid (Table 2) Our results indicate that pseudothymine stimulates the incorporation of labelled adenine and uracil into the insoluble RNA fraction compared with the water control (Table 3) The effect of pseudothymine, which has a pyrimidine structure, is analogous to the hormone-like activity of benzyladenine This may indicate that both purine and pyrimidine derivatives have the same biological effectiveness

The purine and pyrimidine derivatives which we investigated were incorporated in very small amounts into the insoluble RNA, but they were characteristically accumulated in the soluble RNA (*t*RNA ?) Assuming the Watson–Crick model, it is evident that the base-analogues act on the stimulation of protein synthesis by increasing the level of *t*RNA. We could, however, demonstrate that the purine and pyrimidine derivatives have a stimulating and regulating effect on the incorporation of natural nucleobases into the insoluble RNA, so that it is impossible to interpret the stimulating effect on the basis of the Watson–Crick model It is interesting, however, that base-analogues are accumulated only in the soluble RNA fraction (*s*RNA, *t*RNA), but we do not know the form in which they are involved in the stimulation of incorporation of natural nucleobases into the RNA We finally conclude that not only purine but also pyrimidine derivatives, such as pseudothymine, have a hormone-like effect, by stimulating nucleic acid synthesis

L-2-Amino-3-phenyl-1-propanol (L-Phenylalaninol) as a Constituent of a Fungal Metabolite

WE have investigated the structure of a biologically active polypeptide compound, antiamoebin, isolated from the mycelium of the organism *Emericellopsis poonensis* Thirum by Thirumalachar (personal communication) On acid hydrolysis this substance gave an organic base which was identified as L-2-amino-3-phenyl-1-propanol (L-phenylalaninol)

When refluxed with 6 N hydrochloric acid for 28 h, antiamoebin gave a basic compound, which gave a positive ninhydrin reaction and R_F value of 0 72 in the solvent system *n*-BuOH AcOH H_2O, 4 1 5 The base was purified by distillation and recrystallization from benzene The melting point was 95° C, and $[\alpha]_D^{24^\circ}$ − 25 76 (C 3 3, ethanol) analysis gave C 71 78 per cent, H 8 52 per cent, N 8 93 per cent The molecular weight (by the Rast method) was 153 From the analysis and the molecular weight the molecular formula was calculated as $C_9H_{13}NO$ (calculated values for $C_9H_{13}NO$, C 71 52 per cent, H 8 61 per cent, N 9 27 per cent and a molecular weight of 151)

Characteristics of derivatives were as follows. (1) Dibenzoyl derivative, melting point 169° C, analysis gave C . 76 9 per cent, H 5 82 per cent, N 3 62 per cent and a molecular weight (by the Rast method) of 359. The calculated values for $C_{23}H_{21}NO_3$ are C 76 88 per cent, H 5 85 per cent, N 3 89 per cent and molecular weight 359. (2) Acid oxalate, melting point 180° C, analysis gave C 55 00 per cent, H 6 16 per cent, N . 5 80 per cent The calculated values for $C_{11}H_{15}NO_5$ are C 54 77 per cent, H 6 22 per cent, N · 5 81 per cent

These properties identified the base as L-2-amino-3-phenyl-1-propanol The reported values for this compound are melting point 95° C, $[\alpha]_D^{24^\circ}$ − 23 3 (C 2·01, methanol)[1] and the melting point for acid oxalate 177° C (ref 2) The identity was further confirmed by the mixed melting point, infrared spectrum and paper chromatographic behaviour of the authentic sample

We thank Dr M J Thirumalachar for his encouragement, Dr N. Narsimhachari for helpful discussion, V B Joshi for microanalysis and Dr Nitya Nand for supplying L-phenylalaninol

RNA in the Elementary Bodies of Trachoma Agent

TRACHOMA agent, a member of the psittacosis–lymphogranuloma–trachoma (PLT) group, is an obligate parasite of the conjunctival cells in the human eye Some strains, at least, retain their infectivity for the human eye after adaptation to growth and several passages in human cell cultures[1,2]. The infectious particles of trachoma agent are 0·3 μm in diameter and contain both DNA and RNA[3]

After entry into the host cell cytoplasm, the elementary bodies develop into large compact inclusion bodies containing glycogen[4,5] These contain non-infectious structures in which the infectious elementary bodies are formed towards the end of the growth cycle. In this respect, the trachoma agent differs from the psittacosis agent The latter forms diffuse cytoplasmic inclusions[4], consisting of large reticulated forms which replicate by binary fission to produce elementary bodies similar to those of trachoma agent[6] Both the large forms and the elementary bodies of psittacosis agent contain DNA and RNA[7], and the large forms contain soluble RNA species[8,9], ribosomal subunits and ribosomes[10] This investigation deals with the nature of the RNA species and the ribosomal subunits in the infectious elementary bodies of trachoma agent

We used the T'ang strain of trachoma agent, propagated in *FL* cells[11] for 350–400 passages Two-day-old *FL* cells in tube cultures (about 2×10^5 cells/culture) were transferred to a chemically defined medium[12] and infected with enough agent to ensure the development of one inclusion body in each cell Each of the infected cultures contained 1 μCi of ^{3}H-cytidine (specific activity, 2 2 Ci/mmole, ICN Corp , USA) and was incubated at 37° C To label proteins, the concentration of leucine was reduced to one-fortieth of that in the defined medium and 1 μCi ^{14}C-leucine (specific activity 165 mCi/mmole, Radiochemical Centre, Amersham) was added to each *FL* culture Forty-five hours after inoculation with trachoma the medium was removed and the infected cells were washed at room temperature with an 8 per cent (w/w) sucrose solution made in 10^{-2} M *tris* hydrochloric acid buffer at *p*H 7 5 and immediately adjusted to 4° C The cells were scraped into about 0 1 ml of the sucrose solution and disrupted by pipetting through a narrow capillary The nuclei, which are not damaged by this process, were centrifuged for 5 min at 1,500 r p m at 4° C, and the cytoplasmic fraction was removed The elementary bodies were purified by zone centrifugation in sucrose gradients (15–30 per cent w/w) formed on top of a cushion of 0 4 ml of 45 per cent (w/w) sucrose, prepared in *tris* buffer The gradients were centrifuged for 30 min at 10,000 r p m in the *SW* 39 rotor of the Spinco model *L*2 preparative ultracentrifuge at 7° C The material in the cushion was removed, diluted and banded in a sucrose gradient (30–45 per cent w/w) for 45 min at 10,000 r p m at 7° C About 99 per cent of the particles which band in the middle of the gradient are elementary bodies as judged by electron microscopy[3] When necessary, the infected cells were homogenized in 10^{-2} M *tris* buffer containing 1 5×10^{-3} M Mg^{++} and 10^{-2} M KCl (*tris*+Mg^{++} buffer) The elementary bodies were purified in sucrose gradients (30–45 per cent w/w) made in the same buffer They were then removed from the gradients and the optical density (*O D*) of the particle suspension was determined at 260 mμ wavelength The yield of elementary bodies from about 2×10^6 infected *FL* cells is 4×10^8 plaque forming units as determined by the plaque assay developed by Bernkopf[13] Such a purified preparation had an absorption of 1 *O D* unit at 260 mμ wavelength Direct isolation of RNA from the elementary bodies of trachoma agent was achieved by dissolving the particles in 1 per cent solution of sodium dodecyl sulphate (SDS)[14] The dissolved particle suspension was diluted three-fold with SDS buffer and carefully layered with a plastic spoon on top of a sucrose gradient (15–30 per cent w/w) made in SDS buffer Care was taken to prevent shearing of the DNA of this agent, which contains about 40 per cent of the radioactivity of the incorporated ^{3}H-cytidine The gradients were spun in the *SW* 25 1 rotor for 18 h at 24,000 r p m. at 25° C The gradients were collected through a Gilford spectrophotometer and each fraction was divided one portion was precipitated with cold 20 per cent trichloroacetic acid (TCA) and the other was treated with 1 N potassium hydroxide for 18 h at 37° C before treatment with TCA. The alkali was used to determine the amount of radioactive isotope which was incorporated into DNA, which is resistant to treatment with alkali The acid-precipitable radioactivity was collected on 'Millipore' filters and counted in a Packard liquid scintillation counter In the experimental conditions, all the DNA sedimented to the bottom of the centrifuge tube When necessary, the cytoplasmic fractions of non-infected HeLa, *FL* or *BSC*$_1$ cells were used as markers for ribosomes and as a source of ribosomal RNA

To obtain ribosomal subunits from the elementary bodies of trachoma agent, the particles were disrupted by two methods. (*a*) To a suspension of elementary bodies, Mg^{++} was added to a final concentration of 3×10^{-3} M, the suspension was diluted threefold with *tris* buffer containing 3×10^{-3} M Mg^{++} and disrupted with 1 per cent sodium deoxycholate (DOC, N B Co , USA) (*b*) To the suspension of elementary bodies, Mg^{++} was added to a final concentration of 10^{-2} M, and the particles were treated in the MSE ultrasonic disintegrator for 3 min at 1 5 A The suspension was diluted three-fold in *tris* buffer containing 10^{-2} M Mg^{++} and layered with a plastic spoon on top of a sucrose gradient (15–30 per cent w/w) prepared in the same buffer The gradients were centrifuged for 18 h at 18,000 r p.m in the *SW* 25 1 rotor at 7° C, and collected through a Gilford spectrophotometer Each fraction was divided into two portions, one of which was treated with TCA and the other first with alkali and then TCA

The results (Fig 1) demonstrate the nature of the RNA species isolated from the elementary bodies of trachoma agent Three RNA species with sedimentation coefficients of 21*S*, 16*S* and 4*S* were obtained The sedimentation coefficients were determined by comparison with the sedimentation of animal cell ribosomal RNA (28*S* and 16*S*) centrifuged either together with trachoma RNA or on separate gradients About 70–75 per cent of the radioactive RNA is found in the 21*S* and 16*S* RNA species present in the elementary bodies and the rest in the 4*S* RNA This indicates that no cellular 28*S* RNA is present in the purified preparations of the trachoma elementary bodies as contamination from the host cells

The localization of RNA within the infectious elementary bodies was also investigated The particles were disrupted with DOC (method *a*) and centrifuged in sucrose gradients in the conditions used for the isolation of ribosomal and ribosomal subunits from HeLa cells[15] Fig 2*A* shows that trachoma RNA sediments in the sucrose gradient as two subunits with sedimentation constants of 53*S* and 30*S*, respectively Ribosomal subunits are obtained when Mg^{++} is present in the *tris* buffer at concentrations of 10^{-2} M or 3×10^{-3} M (Fig 2*A*)

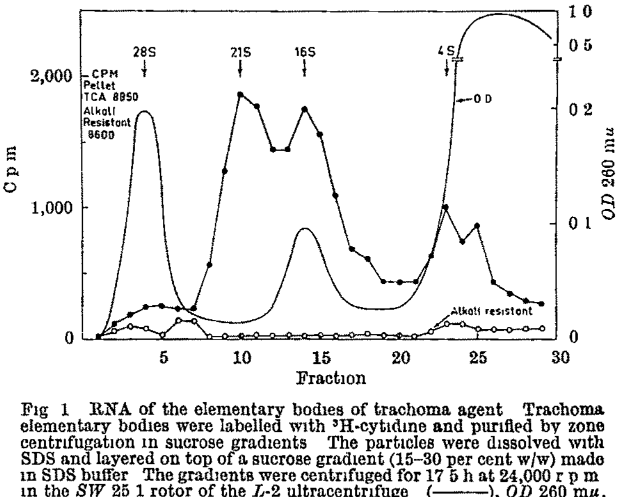

Fig 1 RNA of the elementary bodies of trachoma agent Trachoma elementary bodies were labelled with ^{3}H-cytidine and purified by zone centrifugation in sucrose gradients The particles were dissolved with SDS and layered on top of a sucrose gradient (15–30 per cent w/w) made in SDS buffer The gradients were centrifuged for 17 5 h at 24,000 r p m in the *SW* 25 1 rotor of the *L*-2 ultracentrifuge (———), *OD* 260 mμ, (—●—), TCA precipitable radioactivity, (—○—), alkali resistant radioactivity

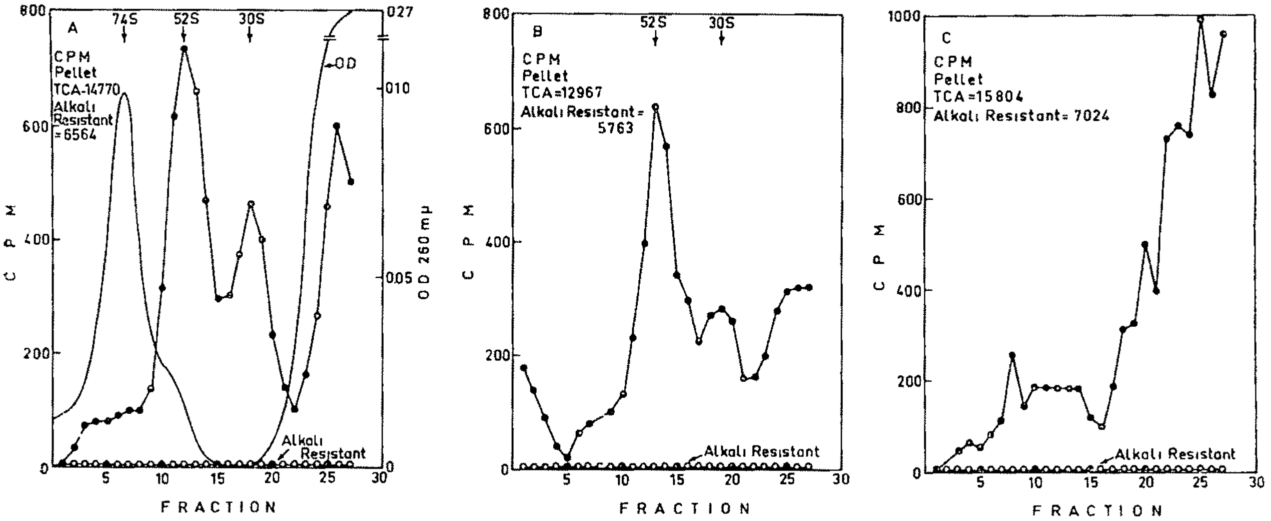

Fig 2 Effect of Mg++ concentration on the isolation of ribosomal subunits from the elementary bodies of trachoma agent Elementary bodies, purified by zone centrifugation in sucrose gradients, were divided into three portions to which different Mg++ concentrations were added *A* 3×10^{-3} M Mg++, *B*, 1 5 $\times 10^{-3}$ M Mg++, and *C*, no Mg++ added. The samples were treated with DOC and centrifuged in sucrose gradients (15–30 per cent) made in *tris* 10^{-2} M and supplemented with Mg++ at concentrations of *A*, 3×10^{-3} M, *B*, 1 5 $\times 10^{-3}$ M, and *C*, 3×10^{-3} M The gradients were centrifuged for 17 h at 17,000 r p m at 7° C (———), *OD* 260 mμ, (—●—), TCA precipitable radioactivity, (—○—), alkali resistant radioactivity

and also 1 5 $\times 10^{-3}$ M (Fig 2*B*) Without Mg++, all the RNA is found at the top of the sucrose gradient which shows the lability of ribosomal subunits in the absence of Mg++ (Fig 2*C*). Attempts were made to isolate the RNA from the different ribosomal subunits and to determine the *S* value by zone centrifugation in SDS sucrose gradients From the 52*S* and 30*S* ribosomal subunits, 20*S* and 16*S* RNA molecules, respectively, were isolated and identified

To characterize further the ribosomal subunits, the elementary bodies of trachoma agent, labelled in the RNA with ^{3}H-cytidine and in the proteins with ^{14}C-leucine, were purified by zone centrifugation in sucrose gradients The particles were disrupted with DOC and the ribosomal subunits were isolated in sucrose gradients Fig 3 shows that radioactive RNA is found in the 52*S* and 30*S* bands Radioactive proteins can be clearly detected in the 52*S* subunits The large amount of labelled proteins which sediment into the gradient masks the 30*S* subunit

In these conditions, there was no evidence for intact ribosomes in the elementary bodies of trachoma agent Sonic treatment (method *b*), which releases about 80 per cent of the RNA, was used to break the elementary bodies and 52*S* and 30*S* ribosomal subunits—not ribosomes—were obtained Furthermore, when the elementary bodies of trachoma agent were prepared and purified in *tris* and Mg++ buffer and dissolved in 1 per cent DOC, ribosomal subunits but not ribosomes were obtained

This study of the nucleic acids of the infectious elementary bodies of trachoma agent has demonstrated the presence of three RNA species with sedimentation constants of 21*S*, 16*S* and 4*S*, respectively The trachoma RNA species resemble in their behaviour the ribosomal RNA species isolated from the elementary bodies and the reticulated forms of psittacosis agent[8] Using the present techniques, 52*S* and 30*S* ribosomal subunits and 21*S* and 16*S* ribosomal RNA were isolated from purified elementary bodies of the 6 *BC* strain of psittacosis agent (unpublished results of Sarov and Becker) Similarly, ribosomal subunits with sedimentation constants of 50*S* and 30*S*, but not ribosomes, were isolated from the purified developing reticulated forms of psittacosis agent[10]

The ribosomal RNA and subunits of both trachoma and psittacosis agents resemble those of bacterial cells[16], which also have sedimentation constants of 50*S* and 30*S* by contrast with the 60*S* and 40*S* ribosomal subunits of animal cells[15] The absence of ribosomes in the sucrose gradient analyses of the elementary bodies of trachoma agent may be caused by (*a*) lability of ribosomes which dissociate into subunits, (*b*) attachment of ribosomes to membranes with consequent failure of release from the disrupted elementary bodies or (*c*) the assembly of ribosomal subunits into ribosomes only in the presence of newly synthesized messenger RNA molecules[15,17] which are formed only after the entry of the infecting elementary bodies into the host cell cytoplasm Further experiments are in progress to define the nature and synthesis of trachoma ribosomes and ribosomal subunits

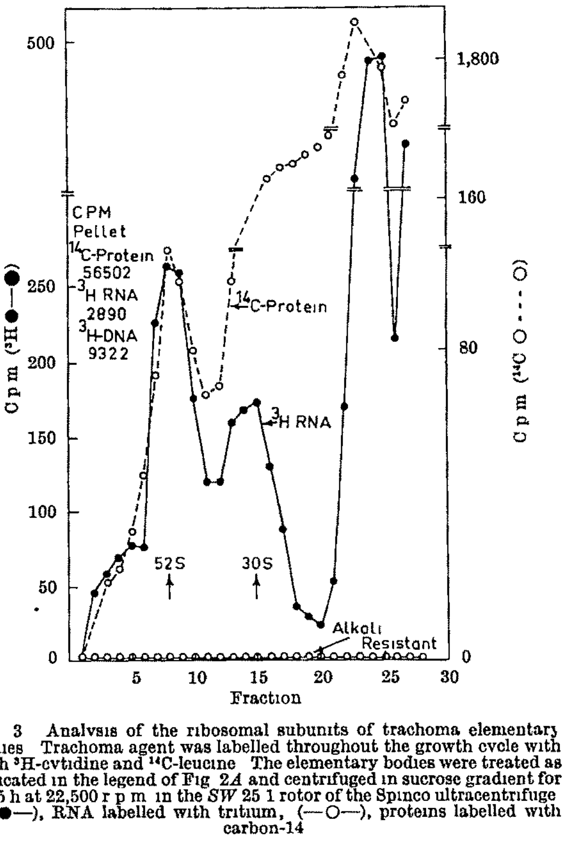

Fig 3 Analysis of the ribosomal subunits of trachoma elementary bodies Trachoma agent was labelled throughout the growth cycle with both ^{3}H-cytidine and ^{14}C-leucine The elementary bodies were treated as indicated in the legend of Fig 2*A* and centrifuged in sucrose gradient for 15 5 h at 22,500 r p m in the *SW* 25 1 rotor of the Spinco ultracentrifuge (—●—), RNA labelled with tritium, (—○—), proteins labelled with carbon-14

The presence of ribosomal RNA and ribosomal subunits in the elementary bodies of trachoma and psittacosis agents demonstrates the cellular nature of these agents, which clearly differ from viruses[6] The taxonomic position of the PLT group, and the exact relationship between trachoma and psittacosis agents, are yet to be established

Temperature Dependence of Cortisol Binding to Plasma Proteins

THE binding of cortisol to plasma proteins increases with a decrease in temperature No direct measurements have been reported of the effect of temperature on the binding constants of transcortin and albumin, but it has been suggested that as the temperature decreases new binding sites appear on transcortin[1]

The cortisol-binding characteristics of two pools of normal human plasma have been determined at different temperatures, using ultrafiltration of plasma with precautions against adsorptive loss and ethanol denaturation as described earlier[2] The unbound cortisol concentration in plasma water was determined in each plasma pool before and after the addition of known amounts of cortisol The cortisol additions were sufficient to increase the plasma cortisol concentration by 5, 15, 30 and 400 µg/100 ml Plasma 11-OH corticosteroids were determined by the method of Mattingly[3]

If transcortin and albumin each have a single species of binding sites for cortisol with capacities, respectively, P_t and P_a and equilibrium constants K_t and K_a, Tait and Burstein[4] have shown from mass action considerations that with total cortisol concentration T, free concentration F, amount bound to transcortin B_t, and to albumin B_a, then

$$K_t(P_t - B_t) = B_t/F \qquad (1)$$

$$(P_aK_a) = B_a/F \qquad (2)$$

$$T = F + B_a + B_t \qquad (3)$$

Because P_a is very much larger than the cortisol additions used, the binding sites on albumin never approach saturation and P_a and K_a cannot be determined independently Their product (P_aK_a) can however, be determined with good precision

Substitution of equations (1) and (2) into (3) yields

$$T - F = P_t + (P_aK_a)/K_t + 1/K_t + (P_aK_a)\,F - T/F\,K_t \qquad (4)$$

with known values T and F and unknowns K_t, P_t and (P_aK_a) The addition of cortisol to a plasma sample provides further values of T and F with the binding constants unchanged Three such results for T and F (T_1, T_2, T_3 and F_1, F_2, F_3) permit the three unknown constants to be determined, thus

$$(P_aK_a) = \frac{(B_3 - B_1)(a_1 - a_2) - (B_2 - B_1)(a_1 - a_3)}{(F_3 - F_1)(a_1 - a_2) - (F_2 - F_1)(a_1 - a_3)}$$

$$K_t = \frac{(F_3 - F_1)(a_1 - a_2) - (F_2 - F_1)(a_1 - a_3)}{(B_2 - B_1)(F_3 - F_1) - (B_3 - B_1)(F_2 - F_1)}$$

and

$$P_t = B_2 + (a_2 - P_aK_a - 1)/K_t - (P_aK_a)\,F_2$$

where

$$B_1 = T_1 - F_1,\ B_2 = T_2 - F_2,\ B_3 = T_3 - F_3,\ \text{and } a_1 = T_1/F_1,\ a_2 = T_2/F_2,\ a_3 = T_3/F_3$$

The values selected for T critically affect the precision with which the binding constants can be measured The lowest T_1 possible leads to the best estimate of K_t, a value of T_2 approximately equal to P_t is necessary for accurate determination of P_t and the best estimate of (P_aK_a) is given by a value of T_3 at least three times greater than P_t Using cortisol additions of zero, 15 and 400 µg/100 ml , the precision of estimates of P_t and (P_aK_a) is about ± 5 per cent (1 *S D*) and of K_t approximately ± 10 per cent (1 *S D*)

Table 1 EFFECT OF TEMPERATURE ON BINDING CONSTANTS OF TRANSCORTIN (P_t, K_t) AND ALBUMIN (P_aK_a)

Temperature (degrees C)	Plasma I P_t M/1 × 10⁷	 K_t 1/M × 10⁻⁷	 (P_aK_a) —	Plasma II P_t M/1 × 10⁷	 K_t 1/M × 10⁻⁷	 (P_aK_a) —
10	4 6	44	3 7	7 5	26	3 7
25	4 9	26	3 1	—	—	—
37	5 1	11	2 6	6 7	9	2 8

The results obtained are shown in Table 1 The small changes of P_t with temperature are probably not significant The most marked effect of decreasing temperature is an increase in K_t with a lesser increase in (P_aK_a) The calculation of these constants is based on the assumption that transcortin retains at low temperature its characteristic of having only a single species of binding site. A Scatchard plot[5] of the full data from one of the plasmas is shown in Fig 1 Deviations from linearity on such a plot provide a sensitive indication of inhomogeneity of binding sites[6] The figure shows good linearity, and so

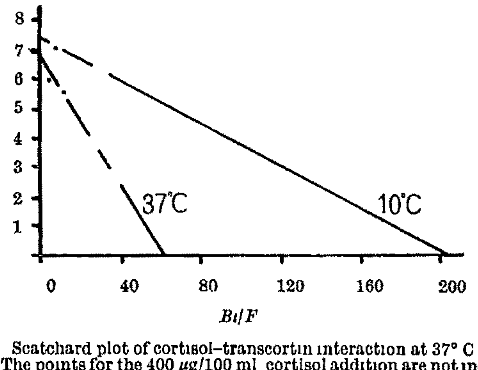

Fig 1 Scatchard plot of cortisol–transcortin interaction at 37° C and at 10° C The points for the 400 µg/100 ml cortisol addition are not included because they were used to calculate P_aK_a

it may be concluded that a single species of binding site is predominant on transcortin both at 37° C and at 10° C

Regulation of Insulin Secretion by Short Chain Fatty Acids

Evidence is accumulating that in some mammalian species there may be a direct effect of short chain fatty acids on the secretion of insulin from the pancreas Thus it has been shown that octanoate causes a marked release of insulin from slices of rat pancreas[1] Furthermore, butyrate was found to evoke a rapid and sustained elevation of serum insulin when infused into adult sheep[2] These results contrast with the lack of effect on insulin secretion when longer chain fatty acids, such as palmitate, are incubated with pancreas slices[3]

With the development of methods for the isolation of islets of Langerhans in large numbers[4,5] it has become possible to study the mechanism of insulin secretion by the measurement of concentrations of metabolic intermediates. We have measured intracellular concentrations of glucose-6-phosphate following incubation of rat islets with butyrate, octanoate and citrate The results suggest that short chain fatty acids are important regulators of glucose-6-phosphate levels in pancreatic islet cells, and in this way they may influence insulin secretion.

Islets of Langerhans were isolated from pancreas by collagenase digestion of tissue taken from male albino Wistar rats which had been fasted overnight The separated islets were divided into groups of ten and incubated in bicarbonate-buffered medium containing albumin together with either glucose, octanoate, butyrate or citrate In each experiment, the effects of low and high glucose were compared with those of low glucose plus organic acid After 30 min of incubation at 37° C the medium was sampled for determination of its insulin content by the immunoassay of Hales and Randle[6]. Rat insulin provided standards for the assay The islets from each group of incubation flasks were then pooled in pointed centrifuge tubes, the medium removed and the islets quickly frozen to $-76°$ C by immersion of the tube in a bath of solid carbon dioxide and ethyl alcohol They were then subjected to sonication for 20 s, after the addition of perchloric acid (0 1 ml /ten islets) The supernatants from the perchloric extracts were then neutralized with potassium carbonate, before the estimation of glucose-6-phosphate by the enzymatic cycling procedure described by Lowry *et al* [7] This gave us reproducible results in good agreement with those already reported by Matchinsky[8] for rat islets Similar concentrations of glucose-6-phosphate have been reported by Idahl and Hellman[9] for islets taken from obese hyperglycaemic mice, in which β-cells constitute more than 90 per cent of the islet tissue

The results obtained are shown in Table 1, which shows that butyrate, octanoate and citrate all stimulate the release of insulin from isolated rat islets of Langerhans, and that paralleling the secretion there is an increase in the intracellular concentrations of glucose-6-phosphate in the islets

These results can be explained as an effect of short chain fatty acids on the intracellular accumulation of citrate which may then affect phosphofructokinase, resulting in an inhibition of glycolysis and accumulation of glucose-6-phosphate, as has been suggested by Randle *et al* for other tissues[10]. Furthermore, the results do not support the idea that the release of insulin brought about by sugars is mediated by glycolysis, for, in the presence of fatty acids, glycolysis is inhibited, but rather they suggest that glucose has to be metabolized by some other pathway in order to stimulate insulin secretion We have already indicated that the pentose phosphate pathway may be important in this respect[11]

Table 1 SECRETION OF INSULIN AND THE INTRACELLULAR CONCENTRATIONS OF GLUCOSE-6-PHOSPHATE IN ISOLATED RAT ISLETS OF LANGERHANS INCUBATED IN THE PRESENCE OF OCTANOATE, BUTYRATE AND CITRATE

Addition to medium	Insulin secretion (μ units/10 islets/min, mean ± *S D*)	Glucose-6-phosphate levels ($\mu\mu$moles/40 islets, mean ± *S D*)
2 5 mM glucose	18 ± 4 (20)	25 5 ± 7 0 (8)
20 0 mM glucose	39 ± 6 (20)	59 5 ± 10 0 (8)
2 5 mM glucose + 5 0 mM sodium citrate	37 ± 5 (20)	49 0 ± 12 0 (8)
2 5 mM glucose	18 ± 4 (20)	26 5 ± 5 0 (8)
20 0 mM glucose	38 ± 5 (20)	65 5 ± 11 0 (8)
2 5 mM glucose + 5 0 mM sodium butyrate	33 ± 4 (20)	47 5 ± 10 0 (8)
2 5 mM glucose	19 ± 3 (20)	22 5 ± 5 0 (4)
20 0 mM glucose	40 ± 5 (20)	51 0 ± 5 0 (4)
2 5 mM glucose + 5 0 mM sodium octanoate	38 ± 4 (20)	48 5 ± 7 0 (4)

It is not known whether longer chain fatty acids can also exercise a regulatory effect by this means, because so far it has been difficult to obtain effects of albumin-bound long chain fatty acids on insulin secretion In addition, ketone bodies have also not been shown to be effective in releasing insulin in most species, whether used *in vitro*[3,12] or *in vivo*[13] Thus we found that 5 mM β-hydroxybutyrate did not alter rates of secretion when incubated with isolated rat islets. Nevertheless, ketone bodies and long chain fatty acids may be important in modifying insulin release in certain other species, for Madison *et al.* have obtained effects of these agents in inducing insulin secretion in the dog[14,15]. By contrast, a much more consistent effect of short chain fatty acids on release of insulin has been obtained. Our results indicate that the "glucose fatty acid cycle"[10] may be operative as a means of metabolic regulation in pancreatic islet cells

Clinical and Pharmacological Effects of Monoamine Precursors or Haloperidol in Chronic Schizophrenia

MANY psychotropic drugs have been shown to interfere with monoamine metabolism in the brain[1,2] Recently, interest has been focused on tryptophan and 5-hydroxytryptamine metabolism in mental depression[3,4] During combined treatment with tryptophan and a monoamine oxidase inhibitor (MAOI) in healthy volunteers, mental effects described as drunkenness and hyperreflexia appeared[5] In schizophrenic patients, the same combination of drugs caused central nervous stimulation and varying effects on the disease symptoms[6-8] (reviewed in ref 9) In contrast, 5-hydroxytryptophan also in combination with a monoamine oxidase inhibitor is reported to have no such effects on schizophrenic patients[7,10] This discrepancy may depend on an accumulation of tryptamine after treatment with MAOI and tryptophan but not 5-hydroxytryptophan Because of these findings we have made therapeutic investigations of schizophrenic patients given single doses of monoamine precursors and at the same time made repeated estimations of acid monoamine metabolites in the lumbar cerebrospinal fluid Ashcroft *et al* have pointed out that ventricular CSF rich in acid monoamine metabolites might reach the lumbar tap site if large amounts of cerebrospinal fluid were tapped[11] In our study, however, the concentration of the acid monoamine metabolite which was uninfluenced by the treatments was unaffected by repeated tapping of the lumbar fluid 5-Hydroxyindole acetic acid (5-HIAA) and homovanillic acid (HVA) in the cerebrospinal fluid were estimated by the methods of Roos[12] and Andén, Roos and Werdinius[13] Our patients had been in hospital for many years, and 14 days before these studies were undertaken all treatment was stopped

One patient was given 50 mg of DL-5-hydroxytryptophan intravenously. No mental effects could be observed and there seemed to be no discomfort On the other hand there were considerable changes in the concentration of 5-hydroxyindole acetic acid in the cerebrospinal fluid (Table 1)

Table 1

Patient No	Intravenous injection of	5-HIAA in CSF (μg/ml) Before injection	5-HIAA in CSF (μg/ml) 2 h after injection	HVA in CSF (μg/ml) Before injection	HVA in CSF (μg/ml) 2 h after injection	HVA in CSF (μg/ml) 6 h after injection	HVA in CSF (μg/ml) 24 h after injection
1	5-Hydroxytryptophan, 50 mg	0 047	0 085	0 058	0 059	—	—
2	L-DOPA, 50 mg	0 026	0 038	0 031	0 041	0 077	—
3	Haloperidol, 20 mg	0 026	0 029	0 031	0 048	0 042	0 034
4	Haloperidol, 40 mg	0 041	—	0 044	0 080	0 089	0 10

5-HIAA, 5-Hydroxyindole acetic acid, CSF, cerebrospinal fluid, HVA, homovanillic acid

Another patient was given 50 mg of L-DOPA with no side effects nor apparent influence on the mental state The concentration of homovanillic acid in the cerebrospinal fluid was, however, increased (Table 1) Bernheimer *et al* [14] gave 50 mg of L-DOPA intravenously to both normal subjects and patients with various organic brain diseases but did not observe any changes of the concentration of homovanillic acid in the cerebrospinal fluid

In two schizophrenic patients who, by mistake, happened to receive intravenous haloperidol, 20 and 40 mg, respectively, we could measure the concentrations of homovanillic acid and 5-hydroxyindole acetic acid in the cerebrospinal fluid at intervals up to 24 h after injection These patients had previously been treated with large doses of other neuroleptics but without effect After the injections of haloperidol—they were free of other drugs—the patients were moderately sedated and showed mild orthostatic symptoms Patient No 4 (who received 40 mg) had a moderate hand and foot tremor for 4 days but showed no rigidity or motor unrest There were no changes in the mental state despite mild sedation. The concentration of homovanillic acid in cerebrospinal fluid in this patient doubled within 6 h of the injection The patient who received 20 mg of haloperidol showed no change in the concentration of homovanillic acid in the cerebrospinal fluid (Table 1) It has been shown experimentally that after doses of haloperidol or chlorpromazine comparable with those used in psychiatric therapy, homovanillic acid in the corpus striatum increases significantly[15-17]. It was therefore surprising that only after doses of 40 mg was there a noticeable change in the concentration of homovanillic acid in the cerebrospinal fluid In dogs, however, a similar phenomenon has been encountered A dose of 0 3 mg/kg of haloperidol increased the homovanillic acid in the corpus striatum more than 100 per cent but had no influence on the homovanillic acid in the cerebrospinal fluid (unpublished results of H Andersson).

MICROBIOLOGY

Isolation of *Salmonella typhimurium* Mutants with Increased Recipient Ability by the Use of *R* Factor

SEXUAL recombination occurs only at very low frequencies between *Escherichia coli* Hfr and *Salmonella typhimurium* recipients[1-5] Frequencies of transfer of *R* factors[6] from *E coli R*+ to *S typhimurium R*- are also very low (10-7/ donor)[7] Thus a characteristic feature of the mating of *E coli* with *S typhimurium* is the low recipient ability of *Salmonella* strains The low recipient ability of *Salmonella* was overcome by isolating fertile mutants by an indirect selection method in *S typhimurium LT-7 mut*[5] We reported that these fertile mutants are restrictionless and modificationless for foreign deoxyribonucleic acids (DNA) such as phage *P*22 DNA, *R* factors, *F* factor and bacterial chromosomes[8]. Eisenstark[9] found that the frequencies of hybridization between *E. coli* Hfr and *S. typhimurium* *LT*-2 are increased by treatment of *LT*-2 recipients with *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (NG). We have found that two types of mutants of *LT*-2 selected by the transfer of an *R* factor from *E. coli* *K*-12 behaved, after elimination of the *R* factor with acridine orange, as good recipients of *E. coli* chromosomes, in the same way as was shown for *K*-12 (*P*1) by means of *F*-prime factor transfer[10].

For the isolation of mutants with high recipient abilities for the transfer of *R* factor from *E. coli* about 5×10^8 cells of a logarithmic phase culture of *LT*-2 *cys D*-36 (cysteine-requiring) were washed and suspended in 20 ml of saline containing 40 µg/ml of NG. These cells were incubated without aeration at 37° C for 1 h. After washing the cells by centrifugation, they were suspended in 10 ml of fresh 'Penassay' broth (Difco) and incubated overnight without aeration at 37° C. A sample (5 ml.) of this culture was added to an equal volume of fresh 'Penassay' broth and incubated with aeration until the cell titre reached about 5×10^8/ml. Of this culture, 5 ml was mixed with an equal volume of a culture of *E. coli* *CSH*-2(222) (a methionineless, F^- substrain of *K*-12 with an *R* factor 222 carrying the markers of resistance to sulphonamide, streptomycin, chloramphenicol and tetracycline) grown to about 5×10^8 cells/ml in a 200 ml Erlenmeyer flask. The mixture was incubated without aeration at 37° C for 6–8 h. Then 0.1 ml samples of the mixture were plated on minimal agar containing 50 µg/ml of *l*-cysteine and 25 µg/ml of chloramphenicol or 8 µg/ml of tetracycline hydrochloride.

Samples without the treatment with NG gave none or few colonies per plate and those treated with NG gave more than ten colonies per plate. After successive single colony isolations from those colonies, *R* factor was eliminated by the treatment with 20 µg/ml of acridine orange[11]. It was shown that the drug resistance markers of the *R* factor were eliminated as a whole. Most clones of *LT*-2 *cys D*-36 thus obtained from the samples treated with NG gave increased recipient abilities for the transfer of *R* factor from *K*-12 R^+, whereas all clones, as far as studied, from the samples without NG treatment gave low recipient abilities comparable with the original *LT*-2 *cys D*-36. We refer to those mutants as *LT*-2 *Rfer*1 (*fer* = fertile) and the original *LT*-2 *cys D*-36 as *LT*-2 *Rinfer* (*infer* = infertile).

In the next step, it was attempted to isolate mutants with better recipient abilities from *LT*-2 *Rfer*1. About 10^8 cells of a logarithmic phase culture of *LT*-2 *Rfer*1 were suspended in 10 ml of 'Penassay' broth containing 40 µg/ml of NG. These cells were incubated with aeration at 37° C overnight (it was found that treatment with NG in saline for 1 h did not give satisfactory results). After washing the cells by centrifugation, they were suspended in 'Penassay' broth and grown to about 5×10^8 cells/ml by aerating at 37° C. The procedure thereafter was identical to that in the first step. Mutants isolated by the second step procedure had higher recipient abilities than *Rfer*1. These mutants are referred to as *LT*-2 *Rfer*2. The donation of *R* factor from *E. coli* to *Salmonella* did not result in the transfer of chromosomal markers to a measurable extent when studied for lactose and cysteine markers.

The frequencies of transfer of *R* factor from *CSH*-2-(222) to various *Salmonella* mutants and the frequencies of recombinants between *K*-12 Hfr and various *Salmonella* mutants are shown in Tables 1 and 2, respectively. Table 3 shows the efficiencies of plating (eop) on various *Salmonella* mutants of phage *P*22 (a clear mutant) grown on various *Salmonella* derivatives. *LT*-2 *Rfer*1 and *Rfer*2 as well as *LT*-7 *fer* gave the highest eop of phage *P*22 grown on any strain, while the eop of phage *P*22 grown on these strains were about 10^{-4} on *LT*-2 *Rinfer* and *LT*-7 mut^+ as compared with the eop on *Rfer*1 and *Rfer*2 strains. The eop of phage *P*22 grown on *LT*-2 *Rinfer* and *LT*-7 mut^+ were about equal on all the strains. The modification of phage *P*22 grown on *LT*-2 *Rinfer* and *LT*-7 mut^+ was completely lost within one cycle of growth of the phage in *LT*-2 *Rfer*1 or *Rfer*2. There was no difference in the adsorption to various *Salmonella* mutants of phage *P*22 grown on any of these strains. Degradation of DNA of ^{32}P-labelled phage *P*22 grown on *LT*-7 *fer* occurred up to 40 per cent in the infection of *LT*-7 mut^+ or *LT*-2 *Rinfer*[8]. These findings indicate that the mutations leading to *Rfer*1 are modificationless and restrictionless as to phage *P*22.

In the transfer of *R* factor 222 from *CSH*-2(222), *LT*-2 *Rfer*1(222) or *LT*-2 *Rfer*2(222), *LT*-2 *Rinfer* was a very poor recipient (the frequency of transfer was about 10^{-7}/donor). When *LT*- 2 *Rinfer* (222) was used as a donor, *LT*-2 *Rinfer* was a better recipient (the frequency of transfer was about 10^{-4}/donor). These results indicate that *Rfer*2 as well as *Rfer*1 and *E. coli* *K*-12 is restrictionless and modificationless in contrast to *Rinfer* which is considered to be positive in host-controlled restriction and modification.

Table 1. FREQUENCIES OF TRANSFER OF AN *R* FACTOR 222 FROM *E. coli* *CSH*-2(222) TO VARIOUS MUTANTS OF *S. typhimurium* *LT*-2

Fertility of recipient	No. of strain	Frequency of *R* transfer
Rinfer	*LT*-2 *cys D*-36	1.0×10^{1}/ml
*Rfer*1	40–4	2.9×10^{3}
*Rfer*2	1–11	1.4×10^{5}
*Rfer*2	2–41	3.5×10^{4}
*Rfer*1	3–41	2.3×10^{3}
*Rfer*2	4–51	2.4×10^{4}
*Rfer*2	5–51	6.0×10^{4}
F^- (wild type)	$W3102/\lambda^r$	2.6×10^{6}

Mating conditions are described in the text. Duration of mating was 8 h. $W3102/\lambda^r$ is a galactose-negative, λ-resistant, $\lambda^- F^-$ substrain of *E. coli* *K*-12.

Table 2. FREQUENCIES OF RECOMBINANTS IN THE CROSSES OF *E. coli* *W*2252 (Hfr) WITH VARIOUS SUBSTRAINS OF *S. typhimurium*

	Recipient					
	LT-2 *Rinfer*	*LT*-2 *Rfer*1	*LT*-2 *Rfer*2	*LT*-2 *Rfer*2	*LT*-7 *fer*	*W*677/*Sm* F^-
Selected marker	Lactose$^+$	Lactose$^+$	Lactose$^+$	Proline$^+$	Lactose$^+$	Proline$^+$
Frequency per donor cell	$<6.0\times10^{-10}$	1.0×10^{-8}	1.0×10^{-7}	2.8×10^{-7}	3.0×10^{-3}	2.0×10^{-4}

The procedure for conjugation was that of Sanderson and Demerec[13]. *W*677/*Sm* is a threonine, leucine, and thiamine-requiring, mannitol, xylose, maltose, galactose, and lactose-non-fermenting, streptomycin-resistant, F^- derivative of *E. coli* *K*-12.

Table 3. EFFICIENCIES OF PLATING OF A CLEAR MUTANT OF PHAGE *P*22 ON VARIOUS SUBSTRAINS OF *S. typhimurium*

	Efficiency of plating of phage *P*22 grown on					
Indicator	*LT*-7 *fer*	*LT*-7 *mut*	*LT*-7 mut^+	*LT*-2 *Rinfer*	*LT*-2 *Rfer*1	*LT*-2 *Rfer*2
LT-7 *fer*	1.0	1.0	1.0	1.0	1.0	1.0
LT-7 *mut*	1.0×10^{-4}	4.0×10^{-1}	7.3×10^{-1}	2.1	5.6×10^{-3}	1.2×10^{-2}
LT-7 mut^+	3.0×10^{-5}	1.3×10^{-2}	7.2×10^{-1}	1.4	6.1×10^{-5}	1.1×10^{-4}
LT-2 *Rinfer*	6.0×10^{-5}	2.0×10^{-3}	1.1	1.4	7.8×10^{-5}	1.1×10^{-4}
LT-2 *Rfer*1	1.2×10^{-1}	3.4×10^{-1}	1.2	6.5×10^{-1}	7.5×10^{-1}	1.0
LT-2 *Rfer*2	5.0×10^{-1}	3.6×10^{-1}	2.5×10^{-1}	1.0	3.3×10^{-1}	4.4×10^{-1}

During this investigation, we have found that *Rfer*2 mutants are sensitive to coliphages *T*3, *T*7, *W*-31 (ref. 12) and *P*1 to all of which *Rinfer* and *Rfer*1 strains are resistant. Most *Rfer*2 strains were resistant to phage *P*22 and rough in their colonial morphology. These coliphage-sensitive mutants could also be isolated in a single step from *LT*-2 *Rinfer* by the second method referred to. The sensitivity to phage *P*1 of these mutants has made possible the transduction with *P*1 in *S. typhimurium* and between *E. coli* and *S. typhimurium*. The transduction in *S. typhimurium* as well as the phage sensitivity patterns of these mutants will be reported in a later paper.

*Rfer*1 mutants, after transfer of *R* factor and before its elimination, could be easily screened with a spot test by their sensitivity to phage *P*22 grown on *Rinfer* (modified *P*22) and by the absence of their restrictions of *P*22 grown on *Rfer*1 (non-modified phage). *Rfer*2 mutants could be easily screened by their sensitivity to the coliphages

Combined Inhibition of Influenza Virus Reproduction in Cell Culture using Interferon and Amantadine

AMANTADINE hydrochloride is the first synthetic anti-influenza compound which has been successfully tested in human beings[1,2] Results of an investigation showed that none of its derivatives was more effective than amantadine itself Thus attempts to increase the antiviral prophylactic activity of amantadine and to reduce its dosage in order to diminish the toxicity[3] are necessary

The simultaneous administration of amantadine with the other virus inhibitors which interfere with intracellular stages of virus–cell interaction can help to solve both the problems Our experiments have shown that the combination of amantadine with an inhibitor of nucleic acid synthesis (5-fluorouracil) used against influenza *A/WSN* virus[4], and with a moderate inhibitor of protein synthesis (D,L-ethionine) used against fowl plague virus, could produce an additive effect on the reproduction of the viruses in chick embryo cells

A further experiment on combination was undertaken using amantadine and interferon Amantadine has been shown to slow down or block the penetration of influenza A virus particles inside the cells[5], interferon induces the synthesis of hypothetical "translation inhibitor protein"[6] and finally reduces the number of newly formed viral particles[7] The addition of these two activities was expected to produce a mutual enhancement of the antiviral effect Furthermore, prophylactic anti-influenza properties of human interferon in volunteers[8] indicated that such a combination was of practical interest. The results of experiments with the two inhibitors on chick embryo cells infected with influenza *A/WSN* virus are presented here

The assay of multiplication of *WSN* virus in chick embryo cells, and the procedure of preparation and titration of crude allantoic interferon from chick embryos infected with the same virus have been described[9]

When cultures treated with interferon were inoculated with 10^{-3} plaque forming units (PFU)/cell, the replication of virus was inhibited to a certain extent, especially during the first 48 h after inoculation (Table 1) The simultaneous introduction of amantadine with the inoculum also decreased the yields of virus In the presence of both inhibitors the infectious virus was not detected in cells or medium The addition of interferon and amantadine to the medium 1 h after inoculation did not prevent weak virus multiplication during the first 48 h, but practically stopped it after 72 h The inhibitors produced only a marginal provisional effect when added in combination 24 h after inoculation In these conditions, the separate use of inhibitors was not effective (Table 1) In reduced doses the inhibitors were less effective, but their additive effect was well expressed in spite of some rise in the multiplicity of infection (Table 1, experiment 3)

An additive effect of interferon and amantadine on the cumulation of haemagglutinins was also observed in cultures infected at a high input multiplicity (Table 2)

Table 3 presents the proportion of infected cells in the cultures infected at the multiplicity of 10^{-2} PFU/cell The "infectious centres" technique was used The rate of cumulative inhibition was almost ten times higher than could be expected from the product of separate effects of interferon and amantadine The sum of the inhibitors also prevented more effectively the development of cytopathic changes (Table 3)

Multiplicity of infection 10^{-2} PFU/cell.
Doses and introductions of the inhibitors as in experiment 1 of Table 1
* Average of two cultures

Cessation of the process of infection (Table 1, experiments 1 and 2) and the degree of reduction of the proportion of infected cells in the presence of the two inhibitors indicate a synergistic action of interferon and amantadine This can be explained by the nature of the inhibitory action of the preparations Interferon reduces the quantity of virions released from the infected cells, the number of which has already been reduced by the action of amantadine (Table 3) The released particles after adsorption on intact cells are subjected to the action of amantadine, and inhibition of the two phases of virus–cell interaction again occurs It seems likely that if the dosage of inhibitors is sufficient to reduce the number of released and adsorbed viral particles to less than the initial number, the constant presence of the two inhibitory activities and a low multiplicity at the start will lead practically to cessation of the infectious process The inhibitors could not stop the infection when most of the cells were infected or when the doses were low and produced only an additive effect

The method of approach described here can be examined in human volunteers experimentally infected with influenza A2 or else it can be tested during an influenza A2 epidemic Furthermore, in combination with interferon, amantadine can become active against infections caused by viruses which are sensitive to it only *in vitro* such as rubella and parainfluenza[10,11]

IMMUNOLOGY

Regeneration of Bone Marrow Cells and Thymus induced by 19S Alpha-2 Globulin in Irradiated Mice

THE 19*S* alpha-2 globulin isolated by us from the alpha-2 globulin fraction of human serum (obtained from Mann Res Lab , New York) by the procedure of Schonenberger *et al* [1] and identified by electrophoresis on polyacrylamide gel[2] and ultracentrifugation was found to stimulate the regeneration of bone marrow cells in X-irradiated mice (*C*57*Bl*/6) A sample (0 5 mg) of the 19*S* alpha-2 globulin injected intraperitoneally into 33–35 day old mice within an hour of exposure to 170 r produced a significant speeding up in the incorporation of ^{3}H-thymidine into bone marrow cells, as compared with that in irradiated animals injected with saline (Fig 1) Seven days after irradiation 19*S* alpha-2 globulin-injected animals showed an actual overshoot in number of cells of femoral and tibial bone marrow (55 × 10^6/mouse), as compared with unirradiated controls (42 × 10^6/mouse) and irradiated but saline-injected controls (41 × 10^6/mouse), respectively The total DNA content of bone marrow cells at this stage showed a similar picture, the femoral and tibial bone marrow cells of mice injected with 19*S* alpha-2 globulin containing 527 μg of DNA, while the irradiated (saline-injected) controls contained 410 μg and the non-irradiated controls contained 414 μg of DNA

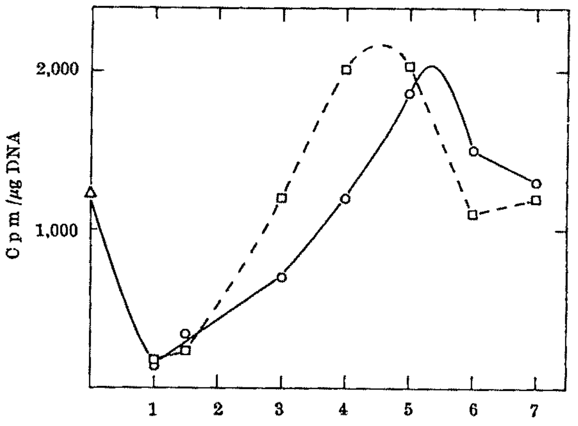

Fig 1 Effect of human serum 19*S* alpha-2 globulin on incorporation of ^{3}H-thymidine into DNA of bone marrow cells of *C*57*Bl*/6 mice after a single exposure to 170 r of X-rays Cells from the tibia and femur of five mice from each group were collected daily and pooled in 4 ml of Tyrode solution and 1 ml samples in duplicate were incubated with 18 mCi/mmole of ^{3}H-thymidine at 38° C for 3 h Nucleic acids were extracted and incorporation measured with a 'Tri-Carb' scintillation counter[3] Solid lines and circles represent the results of the irradiated and saline-treated control animals, and broken lines and squares represent 19*S* alpha-2 globulin-injected, irradiated mice The incorporation of ^{3}H-thymidine in the unirradiated controls is presented at day 0 (triangle) Each point is the mean of the duplicate samples whose values differed by less than 10 per cent

With four irradiations (170 r once a week), and 0 5 mg of the 19*S* alpha-2 globulin injected 1 h after each irradiation, the regeneration effect of the protein fraction was enhanced as compared with a single treatment (Fig 2). Other protein fractions isolated from the alpha-2 globulins of human serum seemed to have marginal or no effect on the regeneration of bone marrow cells after similar radiation treatment.

The same 19*S* alpha-2 globulin also had a stimulating effect on the regeneration of the thymus In mice exposed to 170 r once a week for 4 weeks, injection of 5 μg or more of the globulin after each exposure produced, 3 weeks after the last injection, a significant increase in thymus weight Here again, other fractions isolated from the alpha-2 globulins of human serum had less or no effect. The results of two experiments are presented in Fig 3, in which the effect of 0 5 and 0 1 mg of 19*S* alpha-2 globulin on the regeneration of the thymus is compared with two other protein fractions These two fractions (*B* and *C*) represent a mixture of various proteins which remained in the solution after precipitation of 19*S* alpha-2 globulin at *p*H 5 1 at low ionic strength[1] To this solution ammonium sulphate was added until 60 per cent saturation was reached Precipitate *B* was still found to contain some 19*S* alpha-2 globulin, detectable on electrophoreograms The higher concentration (0 5 mg/injection) therefore still had a stimulating effect on thymus regeneration At the lower concentration (0 1 mg/injection) at which the 19*S* alpha-2 globulin fraction had an effect on thymus regeneration, fraction *B* was ineffective The supernatant (*C*), obtained after treatment with ammonium sulphate, had no significant effect on thymus regeneration at either concentration tested.

Extracts of sheep spleen had previously been shown to have a stimulating effect on thymus regeneration in mice treated as already described[4] By comparing different fractions isolated from sheep spleen, it was found that only those which contained 19*S* alpha-2 globulin (detectable by gel electrophoresis) had a stimulating effect on the regeneration of thymus in irradiated mice These preparations also hastened bone marrow regeneration, preceding the thymus regeneration

This investigation arose indirectly from previous studies on the inhibitory effect of RLP—a protein factor derived from sheep spleen—on radiation leukaemogenesis in *C57Bl* mice[5-7], and from subsequent indications that alpha-2 globulin fractions of human serum had similar effects[8] The effect of 19*S* alpha-2 globulin on radiation leukaemogenesis in *C57Bl* mice is now being investigated Preliminary results indicate that radiation leukaemogenesis is inhibited by 19*S* alpha-2 globulin, as by RLP derived from sheep spleen

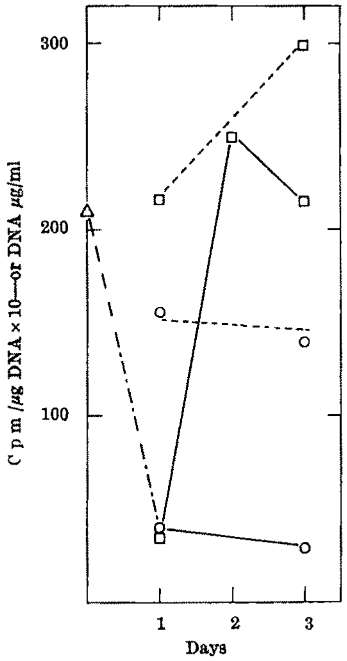

Fig 2 Effect of human serum 19*S* alpha-2 globulin on incorporation of ^{3}H-thymidine into DNA of bone marrow cells of *C57Bl/6* mice after four X-ray exposures (170 r once a week) Experimental procedure as described in Fig 1 The incorporation of ^{3}H-thymidine (unbroken line) and DNA content (dashed line) of aliquots of tibial and femoral cells from the 19*S* alpha-2 globulin injected mice (squares) and saline injected mice (circles) is shown during 3 days after the fourth irradiation The incorporation of ^{3}H-thymidine in unirradiated controls is represented by a triangle at day 0 Each point is the mean of the duplicate samples whose values differed by less than 10 per cent

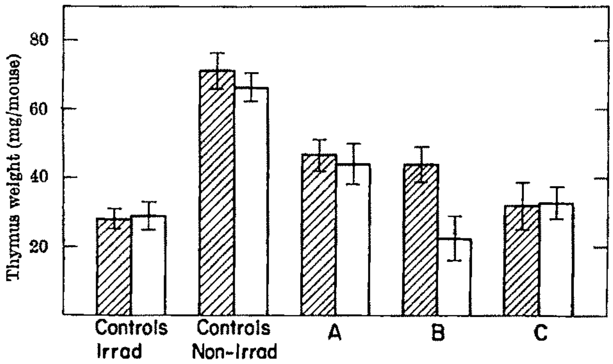

Fig 3 Effect of various fractions isolated from human serum alpha-2 globulins on the weight of the thymus of irradiated mice 3 weeks after the fourth X-ray exposure. Each column represents the mean value of the thymus weight of seventeen mice Confidence intervals (95 per cent) for the means of each group are presented. 0 5 mg (shaded columns) and 0 1 mg (blank columns) of proteins were injected after each irradiation 19*S* alpha-2 globulin (*A*) and two other fractions described in the text (*B* and *C*) were tested The controls were injected with saline

Recently, Hanna *et al* [9] demonstrated a protective effect of 19*S* alpha globulin, isolated from mouse and rat serum, against the lethal action of X-irradiation in mice If this will prove to belong to the alpha-2 globulin group, their results, together with those presented here and elsewhere[8], will support the idea of the special physiological role of 19*S* alpha-2 globulin

Failure to induce Transplantation Resistance against Polyoma Tumour Cells with Syngeneic Embryonic Tissues

MANY tumours contain new transplantation antigens not present in the host tissue of animals in which they arise This applies particularly to those tumours induced by certain oncogenic viruses and chemical carcinogens[1] It is not known whether the factor determining these antigens originates in new nucleic acid derived by viral infection or induced mutation or whether the antigens arise through some type of derepression of normal cellular genes The latter hypothesis suggests that tumour and embryo may share antigens Preliminary data[2] have shown that some of the so-called tumour-specific transplantation antigens of sarcomas induced by 3-methylcholanthrene may be found in embryomas, thus lending support to the derepression hypothesis

To investigate the relationship of embryonic antigens and tumour specific antigens induced by oncogenic viruses, we have chosen two tumour cell lines induced by polyoma virus The origins, properties and tumour specific transplantation antigens of polyoma tumour cells 4198 (originated in *C3H$_f$/HeN* mouse) and polyoma tumour cells 89 (originated in *C57Bl/Ka* mouse) were reported previously[3].

Adult mice (1–2 months old) were given syngeneic 10 day old minced embryos or homografts of polyoma tumours (4198 tumour to *C57Bl* mice or 89 tumour to *C3H* mice) three times within an interval of 2 weeks A third group of mice was given polyoma virus Two weeks after the last inoculation, all mice were challenged subcutaneously with syngeneic polyoma tumour cells.

The results in Table 1 show that mice immunized with syngeneic embryos failed to develop transplantation resistance against syngeneic polyoma tumour cells Strong resistance was induced in mice inoculated with virus The results concerning resistance induced by homografts or polyoma tumours were similar to those reported previously, that is, a moderate degree of resistance was induced in *C57Bl* mice and weaker resistance in *C3H* recipients[3]

Table 1. GROWTH OF SYNGENEIC POLYOMA TUMOUR CELLS IN MICE IMMUNIZED WITH SYNGENEIC EMBRYOS, HOMOGRAFTS OF POLYOMA TUMOUR CELLS AND POLYOMA VIRUS

Recipient and treatment	No of mice developing tumours / No of mice challenged Challenging dose of syngeneic polyoma tumour cells 5 × 10⁵	 5 × 10⁴	 5 × 10³
C57Bl	6/6 (48 31–56)	6/6 (69 58–72)	3/6 (84 58–107)
C57Bl + embryo	6/6 (51 43–52)	5/5 (62 48–70)	4/5 (89 70–110)
C57Bl + homograft	5/5 (54 45–66)	3/5 (65 57–72)	1/6 (86)
C57Bl + virus	3/5 (57 44–86)	1/6 (78)	0/5
C3H	5/5 (24 16–36)	5/5 (32 23–50)	5/5 (42 36–48)
C3H + embryo	4/4 (23 17–24)	5/5 (39 25–51)	5/5 (46 38–60)
C3H + homograft	5/5 (32 25–40)	4/5 (38 25–49)	2/5 (48 43, 54)
C3H + virus	2/5 (48 47, 50)	0/5	0/5

Figures in parentheses are average time of death and range in days

In the discussion of Prehn's paper, Defendi has stated that he has tested two hamster embryo lines transformed by polyoma and one rat polyoma tumour by Prehn's method and obtained negative results, however, no data were presented Our results also failed to confirm the notion that tumour-specific transplantation antigens induced by polyoma virus may arise through derepression of antigens present in embryonic tissue

Role of *X*, *Y* and *Z* Cells in Secondary Immunological Response

ACCORDING to many authors[1–4], the secondary immunological response should consist of responses of cells endowed with immunological memory (*Y* cells in the scheme of Sercarz and Coons[3]) acquired during contact with antigen administered in the previous immunization, and of cells which had come into contact with the antigen for the first time (*X* and *Z* cells according to Sercarz and Coons)

Recently the term "net excess secondary response" has been introduced for the determination of that part of the response which arises out of the reaction to the antigen of cells endowed with immunological memory (*Y* cells) The "net excess secondary response" is calculated by subtracting from the total secondary response the quantity of antibody, which is obtained in control animals when the antigen is administered for the first time[1] This calculation is based on the assumption that the dose used for secondary immunization will produce, on a particular day, the same reaction arising from the inclusion of *X* cells in animals immunized for the first or second time This assumption, however, involves the risk of error, because the antigen, when introduced into the organism for the second time, encounters antibodies which were absent after the first treatment or present in a negligible amount (natural antibodies) These antibodies probably have a marked influence on the fate of the administered antigen and consequently on the course of immunization Their effect is probably similar to that of passively introduced antibodies

To explain the influence of antibodies on the course of immunization, experiments have been carried out with adult rabbits 1 h after an intravenous injection of sheep red blood cells as antigen—serum from rabbits immunized with sheep red blood cells (SRBC) was injected One group of rabbits received injections of serum drawn from a rabbit on the seventh day after a single immunization, this serum contained mainly 19*S* antibodies In another group, serum from a rabbit which had been immunized once a week for 7 months was injected; this serum contained only 7*S* antibodies Antigen only was given to the control group The haemolytic and haemagglutination titres of the two injected sera were identical.

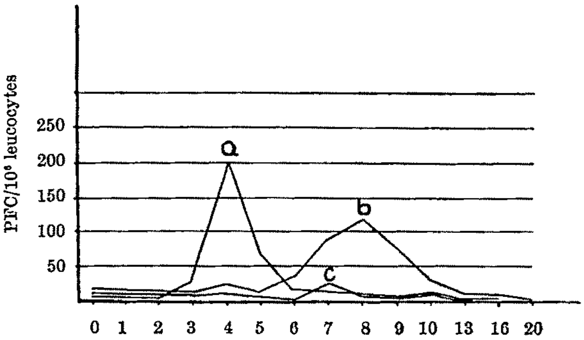

Fig 1 Dynamics of PFC formation in the blood of rabbits *a*, Injected antigen only (3 ml of 10 per cent SRBC), *b*, injected antigen and homologous serum 19*S*, *c*, injected antigen and homologous serum 7*S* Each point represents the average of two rabbits.

Plaque forming cells (PFC) were determined by Šterzl's modification[5] of the Jernes's method[6] (direct haemolytic agar–plaque technique), and antibodies were determined by the method described by Adler[7]

Plaque forming cells were examined using the buffy coat of the peripheral blood, because previous observations (partially described in ref 8) of more than fifty rabbits have shown that the appearance of PFC, their peak and disappearance run parallel to the time course of the PFC in the spleen

Results are shown in Fig 1 The peak of PFC in control rabbits was on the fourth day, and in rabbits which received antigen and homologous antibodies the peak was after 7–8 days—it took nearly twice as long. The peak was also lower, although to a different degree with different antibodies It was markedly reduced by a serum containing 7*S* antibodies, in agreement with the results of other investigators[9,10]

The mechanism of these phenomena probably depends on a decrease in the quantity of antigen caused by the added homologous serum The two sera used contained different types of antibodies, although they were equal titres Thus they decreased the amount of active sheep red blood cells to different degrees[11] Experiments to examine the influence of different doses of antigen on immunization have shown a decreased and delayed reaction of the formation of antibodies when the doses had been reduced[2]

The results in Fig 1 suggest that, when antibodies produced actively act similarly to those produced passively, the peak of cells producing antibodies after a second introduction of antigen should also be delayed by 7–8 days This has been confirmed in experiments with rabbits from which blood samples were taken daily

Table 1 PLAQUE FORMING CELLS IN RABBITS AFTER SECOND IMMUNIZATION

Rabbit No	Days after second immunization 0*	 1	 2	 3	 4	 5	 6	 7	 8	 9	 10	 11

Only eighteen of the twenty-five rabbits examined are included in the table, because the remaining seven had received various doses of antigen

* 5–15 min before second immunization

† Numbers of plaque forming cells/10⁶ of blood leucocytes

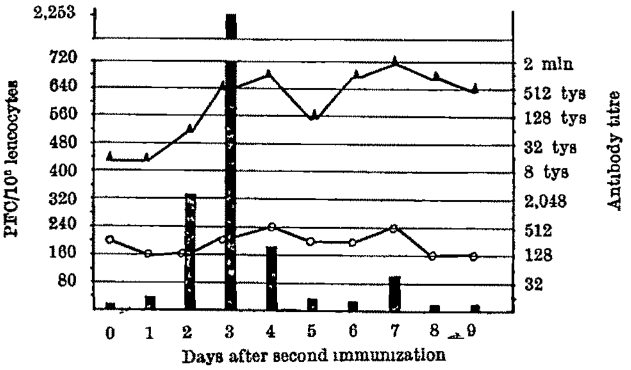

Fig 2 Dynamic of PFC in the blood and of antibody formation in the serum of two rabbits Columns, PFC, ○, agglutinins, ▲, haemolysins

for 9–10 days after the second injection of antigen. Most of the twenty-five rabbits examined showed, as well as a high peak of PFC on the third day after the second injection of antigen, a second peak usually smaller than the first peak, on the seventh (seldom on the sixth or eighth) day (Table 1) Antigen was administered again several days (1–7, sometimes 14) after the first injection An early injection of antigen elicits a secondary response producing chiefly IgM antibody, and so the direct method of detecting PFC can be used here[2] Results of experiments with two peaks of PFC are illustrated in Fig 2.

In the next experiment, 6-mercaptopurine was given to rabbits immunized once and twice with SRBC. 6-Mercaptopurine was given daily in doses of 6 mg/kg of body weight throughout the experimental period beginning on the day of injection of the antigen In rabbits immunized for the second time, the administration of 6-mercaptopurine began on the day of the second injection of antigen. In such a dose this compound has a much more inhibitory effect on the primary than on the secondary response[12,13]

The primary response in two rabbits which had received 6-mercaptopurine was quite low (one animal 8 per cent, the second 25 per cent of the average value for PFC) while rabbits being immunized for the second time showed the first peak only, on the third day, at a rather lower level than in the rabbits not given 6-mercaptopurine The second peak was not observed in any of the three rabbits examined

These experimental results suggest that the secondary response consists of two parts, which differ in the time of appearance of cells producing antibodies and in the height of the peak of these cells The first part is probably Nossal's "net excess secondary response", in which *Y* and *Z* cells are included, and this part is the true secondary response. On the other hand, *X*, *Y* and *Z* cells participate in the second part, which resembles the reaction taking place after the first injection of antigen

PATHOLOGY

Specificity of the Agglutinin in Extracts of Wheat Germ

Extracts of wheat germ prepared to contain lipase have been shown to have the additional property of agglutinating mammalian cells[1] This agglutinin is heat stable, and thus distinguishable from the lipase, which is destroyed by heating to 65° C Aub *et al* suggested that the agglutinin would agglutinate tumour cells more strongly than the equivalent normal cell[1-3] The implication that extracts of wheat germ contain an agglutinin specific for tumour cells is not upheld by the experiments described here, and which involve the ability of extracts of wheat germ to agglutinate red cells and to produce mixed cell agglutination, and the ability of various sugars and salivas to inhibit this agglutinin. Wheat germ lipase (10 mg/ml., Sigma and Calbiochem) was heated at 65° C for 15 min to destroy lipolytic activity[1], the preparation was centrifuged for 10 min at 3,500 r p m to remove the denatured protein, and kept frozen at −20° C

Siliconed glassware was used throughout. To prevent cells from sticking to the glass, they were suspended in a 0 02 per cent solution of crystalline bovine serum albumin in phosphate buffered saline. The cell lines used were kept frozen in liquid nitrogen. A mouse mammary tumour, which arose spontaneously in a *C3H* mouse in August 1962, was obtained from King's College Hospital, London

Wheat germ extract was titrated in two-fold dilutions (0 1 ml. amounts), and an equal volume of 2 per cent red blood cells was added. After thorough mixing, the cells were allowed to react for a minimum of 60 min at room temperature. Agglutination was read macroscopically. The mixed agglutination test was carried out as described by Swinburne, Frank and Coombs[4], except that 0 02 per cent crystalline bovine serum albumin in buffered saline was used as a diluent instead of diluted normal rabbit serum

Direct agglutination was inhibited by mixing equal amounts of wheat germ extract and inhibiting agent (molar sugar solution, salivas) and allowing the mixture to stand at room temperature for 10 min before adding red blood cells These tests were done as chequer board titrations. Mixed agglutination was inhibited by mixing equal amounts of wheat germ extract and inhibiting agent (molar sugar solution, salivas) for 10 min This mixture was then used for sensitizing buccal cells

Wheat germ lipase extract was found to agglutinate the most common types of human red blood cells (A, B, O, AB); also A_3 (one example), $A_{intermediate}$ (one example), Ai (two examples) to almost the same titre (1 · 4 or 1 : 8). Strong mixed agglutination (to a titre of 1 : 32) was observed with buccal epithelial cells from secretor and non-secretor individuals of blood groups A, B and O and human group O indicator red blood cells

Using cultured human diploid tissue cells and O indicator cells a different pattern was observed For no obvious reasons the strength of the reaction varied from completely negative to strongly positive Both of the established human cell lines (Detroit 98 and HeLa 229) gave a very strong mixed agglutination reaction up to a titre of 1 8 Normal mouse spleen and bone marrow preparations gave an extremely strong reaction up to a titre of 1 : 32 The reaction between normal mouse lymph node cells and wheat germ extract was much less strong but definitely positive in a dilution of 1 2. All mouse cell lines (*LM*, *C57*, *C3H*) and the Ehrlich ascites, *BP8*, and mammary mouse tumours gave a mixed agglutination reaction up to a titre of at least 1 . 8 Sarcoma I cells, however, although from a transplantable mouse tumour, failed to give a positive reaction on several occasions when mouse red blood cells were used as indicator cells. When human group O cells were used, the reaction was positive to a titre of 1 2.

Direct agglutination of human red blood cells (groups A, B and O) by wheat germ extract was completely inhibited by human secretor salivas (of blood groups A, B and O) The salivas of non-secretor individuals behaved differently; some inhibited the reaction completely whereas others inhibited it only partly. The agglutinin in wheat germ lipase extract (Sigma) was partly inhibited by D-galactose and L-fucose, it was completely inhibited by *N*-acetyl-D-glucosamine No inhibition was observed with *N*-acetyl-D-galactosamine

No inhibition of mixed agglutination was obtained with either wheat germ preparation using D-galactose and L-fucose as inhibiting agents *N*-Acetyl-D-galactosamine partially inhibited wheat germ extract (Sigma) and completely inhibited wheat germ extract (Calbiochem). *N*-Acetyl-D-glucosamine completely inhibited both wheat germ extracts

Table 1 REACTION OF WHEAT GERM AGGLUTININ WITH TISSUE CELLS DETECTED BY MIXED AGGLUTINATION

	Human O	+ + 1 8

Aub *et al.*[1–3] suggested that tumour cells were more readily clumped by an agglutinin present in the supernatant of heated wheat germ lipase extract than were the homologous normal tissue cells Our study of wheat germ agglutinin was undertaken in the hope that this might eventually be used as a reagent to detect specific cell surface components. The results, however, suggest that the wheat germ lectin is capable of reacting with a wide range of normal and abnormal, adult and foetal cells of human and murine origin The fact that it agglutinates normal red blood cells and normal tissue cells, and fails to agglutinate some tumour cells, is not consistent with the hypothesis of tumour specificity put forward by Aub *et al* In fact, they themselves showed that the lectin reacted with normal mouse red cells and spleen cells It should be pointed out that Aub *et al.* investigated not the combination of wheat germ lectin with cells but the direct agglutination of tissue and tumour cells by wheat germ extract Direct agglutination of cells will be affected by many factors such as distribution and amount of the combining site, dispersal and size of the electrocharge, and it is possible that the difference between tumour and normal cells described by Aub *et al* is governed by these factors, and that it is incorrect to interpret their results as demonstrating a combining site on tumour cells which is absent from the homologous normal cell. Extracts of wheat germ contain a lectin which reacts with a combining group which is very common, and which occurs erratically on a wide variety of cells. The fact that the reaction of the lectin is inhibited by *N*-acetyl-D-glucosamine suggests that this sugar or some similar sugar plays a part at the wheat germ lectin combining site This seems to be the first example of a 'non-specific'' lectin which is inhibited by *N*-acetyl-D-glucosamine[5].

Human Case of Piroplasmosis (Babesiosis)

INFECTIONS with the protozoon *Babesia* occur frequently in wild and domestic animals, but human beings are apparently very rarely affected In the British Isles, cattle are the most commonly infected animals and may develop red water disease. The following case is only the third in the world recorded in a human and the first in the British Isles. It is significant that all three patients had previously undergone splenectomy[1,2].

The patient was a 48 year old deep-sea fisherman from Northern Ireland who had never been abroad. He was admitted to the Renal Unit, Belfast City Hospital, in a moribund state on September 2, 1967. On August 29 he had become vaguely unwell and had passed blood-stained urine By the following day he was jaundiced and a day later he was admitted to Downe Hospital, Downpatrick, in a very ill condition, now deeply jaundiced. He seems to have passed urine only once after arrival in hospital The specimen contained urobilin but there was no report of the presence of blood or haemoglobin He had a pyrexia of 103° F and marked conjunctival injection The haemoglobin level was 7 2 g/100 ml and the specimen was grossly haemolysed. A presumptive diagnosis of Weil's disease was reached and he was transferred to the Renal Unit because of the anuria.

On arrival he was too ill to give a history. He was deeply jaundiced and hypotensive There was a right paramedian abdominal scar with a transverse extension to the left

On September 3 the patient's haemoglobin level had fallen to 4 6 g/100 ml and 2 days later it was 4 0 g/100 ml. Both specimens were markedly haemolysed The blood urea was 312 mg/100 ml , CO_2 combining power 13, Na 120, K 5 3 and Cl 85 mequiv /l , respectively. The total bilirubin was 5 4 mg (direct 1·1 mg)/100 ml , thymol turbidity 2 U and serum transaminase 820 U. The agglutination test for Weil's disease was negative

At this point the diagnosis was thought to be serum hepatitis, because the patient had received several blood transfusions about 4 months earlier in connexion with a difficult gastroenterostomy and vagotomy, during which the spleen had inadvertently been ruptured and removed

The blood count findings on September 5 (haemoglobin, 4 0 g/100 ml.) were red cells $1{\cdot}0 \times 10^6/\text{mm}^3$, haematocrit 12 per cent, mean corpuscular haemoglobin concentration 32 per cent, mean corpuscular volume 120 μ^3, reticulocytes 25 per cent The white cells numbered $46{,}500/\text{mm}^3$, with a differential count of myelocytes 22 per cent, metamyelocytes 19 per cent, neutrophils 47 per cent, lymphocytes 12 per cent The direct antiglobulin (Coombs) test was negative There were thirty-six nucleated red cells per 100 leucocytes The red cells showed macrocytosis and polychromasia Fragmented forms were conspicuous, but the outstanding feature was the presence of numerous intra-erythrocytic organisms These were often circular and frequently vacuolated to form small rings measuring up to 2 5μ in diameter and contained one or sometimes two chromatin dots A variety of shapes, including some budding forms, was noted and occasionally extended loops were seen Infected red cells frequently contained more than one organism, up to eight being present in a single cell

The diagnosis was now considered to be a gross haemolytic anaemia secondary to *P falciparum* malaria, the infection probably having been transmitted in a blood transfusion He had been treated by peritoneal dialysis, massive doses of penicillin and hydrocortisone, and an exchange transfusion was in preparation The patient, however, died that day, the third after admission to the Renal Unit

At autopsy there was profound bile staining of all organs The spleen was absent and the gastroenterostomy was free of ulceration The kidneys were markedly swollen and the bladder contained 25 ml of black urine No malarial pigment was found in any of the usual sites The typical changes of a haemoglobinuric nephrosis were seen in the kidneys All vascular spaces, especially those in the brain, contained numerous immature granulocytes and nucleated red corpuscles

The intra-erythrocytic organisms were later identified as a piroplasm, ***Babesia divergens***. This tick-borne infection was possibly picked up during a caravan holiday in mid-August

We thank Professor P C C Garnham and Mr P G Shute who made the diagnosis We thank also Dr C F Brennan who referred the patient to us

RADIOBIOLOGY

Low Oxygen Enhancement Ratios for Radiosensitive Bacterial Strains, and the Probable Interaction of Two Types of Primary Lesion

WHEN exposed to ionizing radiation, bacterial strains which are deficient in ability to by-pass or repair damage to nucleic acid have lower oxygen enhancement ratios (OERs) than their more radioresistant parents[1] This was predicted from a model in which the principal responsibility for the oxygen effect is attributed to a primary lesion of "type *O*", whereas a different primary lesion, "type *N*", is more easily repaired or by-passed by some strains than others With certain strains, notably ***Escherichia coli B***, the lethal effects of type *N* lesions are readily modified by post-irradiation culture conditions The greater the extent of repair of type *N* damage, the higher the OER[2,3]

Results have been extended by the use of a number of radiosensitive mutants of *E coli B*, selected by Hill, who showed that there was no obvious correlation between sensitivity to ultraviolet light and inability to perform "host cell reactivation" (HCR) on ultraviolet irradiated bacteriophages[4] By using these and other mutants of the parent strain, we have found that the OER is negatively correlated with sensitivity to ultraviolet light, whether or not the strain is HCR⁻ (Table 1)

If variation in radiosensitivity within a group of strains, or with culture conditions for a single strain, depends only on the reparability of type *N* lesions, and if these operate independently of type *O* events, *m* (the OER) and *Do* (the dose to give an average of one lethal event per cell) are linearly related by the expression

$$m = m_N + (m_o - m_N)\lambda o Do \qquad (1)$$

where m_o and m_N are the OERs pertaining to type *O* and *N* events, respectively, and λo is the sensitivity to type *O* events The value of m_N was found to be 1 5 for *E coli B*, and this was supported by calculations, on these assumptions, from independent observations[2,3]

Table 1 OXYGEN ENHANCEMENT RATIOS, X-RAY DOSES (UNDER ANOXIA) TO GIVE AN AVERAGE OF ONE LETHAL EVENT PER BACTERIUM (THAT IS VALUES OF *Do*), AND DOSES OF ULTRAVIOLET LIGHT TO GIVE 10 PER CENT SURVIVAL FOR ELEVEN VARIANTS OF *E coli B*

Variant	HCR + or −	Oxygen enhancement ratio	*Do* (krads)	Ultraviolet dose for 10% survival (ergs/mm²)
Bs-12	−	1 17	2 61	1 8
Bs-1	−	1 77	2 78	4 9
Bs-11	+	2 22	3 29	31
Bs-2	+	2 33	3 94	52
Bs-3	−	2 33	10 4	81
B/rWP₂hcr⁻	−	2 42	12 6	37
Bs-8	−	2 52	11 8	35
B	+	2 74	9 3	236
B/r	+	3 19	15 4	580
B-H	+	3 34	14 9	460
B/rWP₂hcr⁺	+	3 27	17 9	980

Bacteria were cultured before irradiation in Difco broth with 5 g/l of sodium chloride, and plated on solid medium of the same composition Survival curves for X-rays allowed the fitting of slopes from which *Do* could be calculated For ultraviolet irradiation, however, survival curves differed greatly in shape In some cases (for example, *B/r*) a large fraction of the dose to give 10 per cent survival was accounted for by the shoulder, whereas in others (for example, *B*, *Bs*-12) survival curves were steepest at zero dose and became progressively less steep "Sensitivity" to ultraviolet is therefore not definable by a single parameter and the last column must be regarded as a rough guide

The data of Table 1 for a group of mutants of *E. coli B* are plotted in Fig 1, which shows that the data fit roughly with a straight line relationship, but the point for one strain in particular—the highly sensitive *Bs*-12—falls well below the line Furthermore, its oxygen enhancement ratio of only about 1 2 is significantly less than what should be the minimum possible value, 1 5, if the model and the inferred value for m_N were correct The model therefore evidently requires modification

The evidence of correlation between the sensitivity of a family of strains to ultraviolet light and to X-rays in

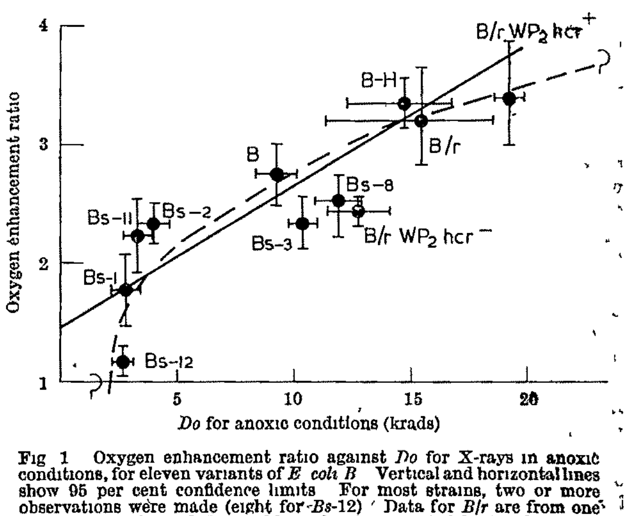

Fig 1 Oxygen enhancement ratio against *Do* for X-rays in anoxic conditions, for eleven variants of *E coli B* Vertical and horizontal lines show 95 per cent confidence limits For most strains, two or more observations were made (eight for *Bs*-12) Data for *B/r* are from one observation only, and the confidence limits computed for the data from that experiment

anoxic conditions, and the negative correlation between OER and radiosensitivity, add to the plausibility of inferring that type N primary lesions occur in nucleic acids[3], and that these primary events have only a minor responsibility for the oxygen effect No such clear inference can be made in respect of primary events of type O These are events which must have at least four to five times the probability of becoming lethal when oxygen is present during irradiation[3] Lipids are readily peroxidized under X-irradiation[5], and so it may well be that type O events are to be associated with damage to "unit membranes" in the cell The idea that radiation might, by its effect on membranes, cause cell death by the release of lytic enzymes is by no means new, and evidence of such action, direct[6] or circumstantial[7], is accumulating

A difficulty in attributing a "component of sensitivity" to membrane damage is, however, the nature of dose-effect relationships observed with ionizing radiation, which strongly suggest that damage to a unique "target" may be caused by one or a few energy loss events; and it is difficult to envisage that a "hit" in a membrane, or the release of a few enzyme molecules, could satisfy this requirement This difficulty would be resolved if the release of lytic enzymes resulted in attack on potentially lethal lesions in the most plausible "vital target" of the replicating cell, the DNA Thus it may be envisaged that there is interaction between the consequence of primary type O events and some of the type N events which would not be lethal without this interaction

If these primary events result in interaction the simple treatment set out here can be only a first approximation Various assumptions could be made from which relationships between m and Do could be predicted, but there are too many possibilities to make this adequately heuristic For example, it could be that the presence of oxygen affects the probability of lethal interaction, as well as the probabilities that type N and type O events are independently lethal It may, however, be interesting to derive an expression for change in m with a change in probability that type N events are independently lethal

In anoxic conditions, let λ_N and λ_o represent respectively the sensitivities to potentially lethal events of type N and type O In anoxic conditions, let p_1, p_2, p_3 and p_4 represent probabilities as follows·

p_1 type N events independently lethal
p_2 type N events lethal as a result of interaction
p_3 type O events independently lethal
p_4 type O events lethal as a result of interaction

In the presence of oxygen, these probabilities become $p_1\,m_N$; $p_2\,m_N$, $p_3\,m_o$ and $p_4\,m_o$ Thus the overall sensitivities in the absence and presence of oxygen are

$$\lambda=p_1\lambda_N+p_2p_4\lambda_N\lambda_O+p_3\lambda_O=1/D_o$$
$$m\lambda=m_np_1\lambda_N+m_Nm_op_2p_4\lambda_N\lambda_O+m_Op_3\lambda_O$$

In this case, even if p_3 and p_4 are constant, λ is not linearly related to p_1, because p_2 may increase as p_1 decreases For example, effective repair processes would reduce the probability that type N events could be independently lethal, but additional lesions might then be available for interaction If the two equations are combined, we have

$$m=m_nm_o\left\{1-\frac{p_1\lambda_N}{\lambda}-\frac{p_3\lambda_O}{\lambda}\right\}+\frac{p_1\lambda_Nm_N+p_3\lambda_Om_O}{\lambda}$$

If p_1 and p_3 are small, λ approaches $p_2p_4\lambda_N\lambda_O$, and m approaches m_Nm_O. If p_1 is near to 1, p_2 is small, and

$$\lambda=p_1\lambda_N+p_3\lambda_O \qquad m\lambda=p_1\lambda_Nm_N+p_3\lambda_Om_O$$

giving

$$m=m_N+p_3\lambda_O(m_O-m_N)D_O$$

Thus, as in the previous treatment, m cannot be less than m_N, though m_N can be less than 1 A possible relationship between m and Do is shown by the dotted line of Fig 1

Besides the evidence from strain *Bs*-12 that the value 1 5 for m_N is too high, Davies[9] has reported a strain of *Chlamydomonas* (*UVS*1) which has an OER of 1 (in terms of the slopes of the survival curves) To account for this observation, Davies put forward a model which he described as an alternative to the one based on two types of primary event with different intrinsic OERs He described this "alternative model" in terms of differential reparability of lesions incurred in the absence and presence of oxygen, and proposed that the *UVS*1 strain of *Chlamydomonas* was deficient in a repair system operating specifically on lesions incurred in the absence of oxygen (for example, cross-linking) but not in its presence Davies's model is, in effect, no different from the one described here, for differences from strain to strain in the reparability of lesions of different types are implicit in the values of the exponents· that is, λ_N, λ_O, $m_N\,\lambda_N$ and $m_O\,\lambda_O$ in my original model, or these parameters with their associated probabilities in the modified version Whichever way the model is described, it is a requirement that, to accommodate a strain which has an OER of 1 or less, there must be a form of damage which is less reparable after irradiation in the absence of oxygen than in its presence, which suggests a value of m_N less than 1 It may yet prove necessary to invoke comparison with the phenomenon long ago observed with bacteriophage, and the kappa particle of *Paramecium*, namely, that in aqueous suspension they are protected by oxygen against the lethal effects of radiation[10-12], so that presumably the overall lethal damage to the nucleic acid core is reduced in the presence of oxygen

I thank Dr J L Moore, Dr A J Forage and Mrs B Knowles for their help I also thank Dr Ruth Hill for sending me various radiosensitive mutants of *E. coli B*

PHYSIOLOGY

ABO Blood Groups, Secretor Status, and Intestinal Mucosal Concentrations of Alkaline Phosphatase

HUMAN serum alkaline phosphatase from some individuals can be separated by starch gel electrophoresis into two components The faster moving zone has the electrophoretic characteristics of liver and bone alkaline phosphatase[1] and, like liver alkaline phosphatase, it is only slightly inhibited by treatment with phenylalanine. By contrast, the slower moving zone has the electrophoretic characteristics of small intestinal alkaline phosphatase[2,3] and its activity is markedly inhibited by phenylalanine[4,5]

The occurrence of this intestinal band of alkaline phosphatase activity in the serum has been found to depend on the ABO blood group and ABH secretor status of the individuals[6-10] The zone is rarely found in the serum of those who are non-secretors, whatever their ABO blood group In secretors, activity is seldom found in those of blood group A, more often in those of group AB, and frequently in those of groups O or B

It is not known, however, whether the transfer of alkaline phosphatase activity from the mucosa to the blood reflects differences in the rate of formation of the enzyme in the mucosa by individuals of varying ABO blood group and secretor status or some other process, such as variations in the rate at which alkaline phosphatase leaks out of the intestinal cell To investigate this problem further, we have measured the concentration of alkaline phosphatase in small intestinal mucosal specimens obtained at operation from individuals of known ABO blood group and secretor status

Small strips of jejunal mucosa were obtained from patients undergoing operations, such as Polya partial gastrectomy, which involved the opening of the small intestine and formation of a gastrojejunostomy

The mucosal specimens were freed of any submucosal tissue and kept at -20° C until they were analysed, preliminary work having indicated that there was no loss of activity during storage After freeze-drying for 12 h, duplicate mucosal samples of about 40 mg were weighed exactly and the alkaline phosphatase was extracted by Ahmed and King's modification of Morton's butanol extraction procedure[11,12] The tissue was homogenized with 2 5 ml of *n*-butanol for 3–5 min, the tubes being surrounded by ice The butanol extract was then emulsified with water and centrifuged at 3,000 r p m for 15 min before the enzyme-rich water layer was removed.

Alkaline phosphatase activity in the samples was measured by the method of Kind and King[13] using phenyl phosphate as substrate, and the results were expressed as King–Armstrong (KA) units per g of dry weight of tissue ABO blood groups were determined by standard agglutination techniques and secretor status by the method of Boyd and Shapleigh[14]

Jejunal mucosal samples were obtained from thirty-five patients of known ABO blood group, and saliva samples for determination of secretor status were obtained in twenty-nine Of those remaining, four died after their operation before saliva samples could be collected and two were considered, from knowledge of their red cell Lewis groups, to be ABH secretors.

Table 1 MEAN MUCOSAL ALKALINE PHOSPHATASE CONCENTRATIONS IN INDIVIDUALS OF DIFFERING ABO BLOOD GROUP AND SECRETOR STATUS

Genetic category	No of samples obtained	Tissue alkaline phosphatase in KA units/g dry weight Mean	Range	*S E M*
Group O and B	21	645	111–995	52
A	13	534	164–828	54
AB	1	387	—	—
Group O and B secretors	14	725	347–995	52
A secretors	7	552	298–828	61
AB secretors	1	387	—	—
All non-secretors	9	425	111–818	81

Table 1 shows the distribution of the results according to ABO blood group and secretor status The same categories as have been found to be relevant to studies of serum intestinal alkaline phosphatase concentrations have been used in this investigation

Mucosal alkaline phosphatase concentrations tended to be higher in individuals of blood groups O and B than in those of group A (mean concentrations 645 and 534 KA units per g dry weight, respectively), but this difference could well have been due to chance (*t*, 1 41, *P*, 0 16) When secretor status was taken into account, however, a gradient was found with the highest mean value being obtained in O or B secretors (725 KA units), an intermediate value (552 KA units) in group A secretors, and the lowest in non-secretors (425 KA units) Fig 1 shows the distribution of the individual results This gradient of activity reflects the patterns previously delineated by starch gel electrophoresis of human serum The low mucosal alkaline phosphatase concentration (387 KA units) found in the single individual of blood group AB, which was judged by red cell Lewis grouping to be a secretor, was an exception to the trend, for serum intestinal alkaline phosphatase activity in group AB secretors tends to be intermediate between that of group O or B secretors and that of group A secretors Even when this anomalous result is taken into account, however, a non-parametric test for trend shows that the observed gradient is very unlikely to be due to chance ($P < 0\ 01$) (ref 15).

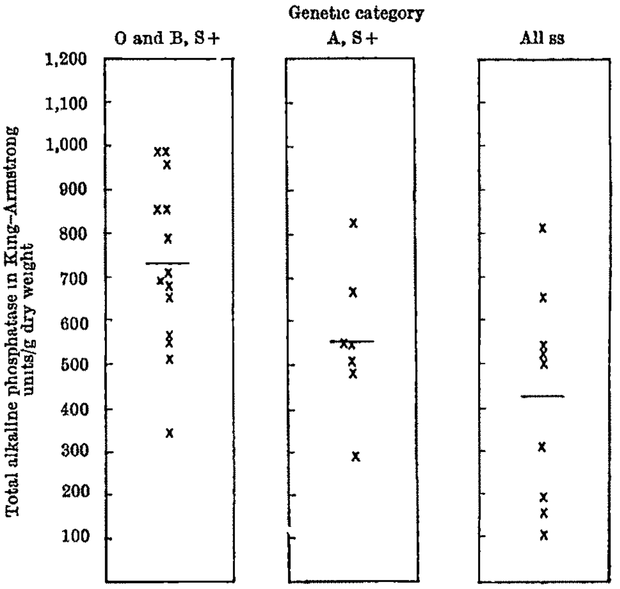

Fig 1 Distribution of individual measurements of tissue alkaline phosphatase concentration according to genetic category, mean concentrations in each group are indicated by horizontal bars

At least two factors apart from ABO blood group and secretor status could affect the jejunal alkaline phosphatase concentration; these are feeding and the anatomical site high or low in the intestine from which the mucosa was removed. Serum intestinal alkaline phosphatase activity is known to rise in the period following a fatty meal[16–18], the change being greatest in O and B secretors and least in non-secretors—changes which presumably could reflect alterations in mucosal phosphatase output. All the patients from whom our mucosal samples had been obtained had fasted for at least 12 h before operation and therefore it is unlikely that the patterns of enzyme activity found reflect differences in feeding

Alkaline phosphatase concentrations in human ileal mucosa are, as in the rat, much lower than those in the jejunum (our unpublished observations) All the mucosal specimens obtained in this study were taken during a standard operative procedure, gastrojejunostomy, and it is unlikely that the site of operation would have varied consistently in individuals of different genetic constitution.

The patterns of intestinal mucosal alkaline phosphatase activity found are therefore likely to reflect real variations in enzyme concentration between individuals of differing ABO blood group and secretor status In an earlier study, Shreffler[19] was unable to show any consistent variation in mucosal alkaline phosphatase concentration between individuals of different ABO blood group and secretor status His results, however, were obtained on mucosal specimens removed at post-mortem examination, and autolysis of the tissues could well have obscured any real variation present The finding of high mucosal enzyme concentrations in those individuals who by genetic constitution would be expected to show most intestinal alkaline phosphatase activity in their serum supports the hypothesis that ABO blood groups and secretor status affect the rate of production of alkaline phosphatase by the mucosal cell If blood groups and secretor status primarily affected the rate of enzyme leakage from the intestinal cell, then mucosal alkaline phosphatase concentrations might be expected to be highest in non-secretors and lowest in O and B secretors, the opposite of the gradient found. Another possible explanation of the serum enzyme variation is that blood group and secretor status affect the rate of removal of intestinal alkaline phosphatase from the circulation. If this were the case, however, then mucosal enzyme concentrations would be unlikely to show any gradient according to the genetic constitution of the individuals.

The precise metabolic role of intestinal alkaline phosphatase is not understood. The rise in the serum concentration of the enzyme after a fatty meal suggests that it may play a part in fat absorption or transport, which therefore might be affected by the ABO blood group and secretor status of the individuals. It has been claimed from studies of blood lipid concentrations in twins that day-to-day variation in free serum cholesterol levels is affected by ABO blood group[20]. On the other hand, the increase of serum turbidity after a fatty meal has not been found to differ with the ABO blood group or secretor status of the individuals. These observations could be reconciled if genetic characteristics affected transport of some specific class of lipid.

We thank the surgeons of the Central Middlesex, Guy's, St. James's, St. Olave's and University College Hospitals for help in obtaining the mucosal specimens.

Storage of Carbon Dioxide in Muscle

WHEN ventilation is suddenly arrested, the carbon dioxide produced by the body is stored within the body tissues as bicarbonate and dissolved carbon dioxide. It has been suggested that this storage of carbon dioxide does not proceed uniformly in all tissues. Rather it has been proposed that the body can be conceived as being composed of multiple compartments which store carbon dioxide at different rates.

In the multicompartment model of carbon dioxide stores proposed by Fahri and Rahn, during apnoea, muscle—because it has a low ratio of perfusion per unit volume—acts as a repository for carbon dioxide produced by other organs[1]. When there is no ventilation, therefore, the carbon dioxide content of the venous blood should be less than the carbon dioxide content of the arterial blood—the reverse of the usual situation.

To test this prediction, we measured the carbon dioxide and oxygen tension, the hydrogen ion concentration and the haematocrit of blood from the femoral artery and vein, and calculated carbon dioxide contents in nine anaesthetized and paralysed dogs during apnoea.

After the paralysed dogs had been ventilated with 100 per cent oxygen for 30 min, arterial and venous blood was obtained from one hind limb, and carbon dioxide production was measured. Apnoea was produced by stopping artificial ventilation. During the apnoeic period, blood samples were obtained at intervals of 1 or 2 min while the trachea of the dog was connected to a spirometer which contained oxygen so that full arterial saturation could be maintained. In three dogs, blood flow in the opposite limb was measured with a rotameter.

Table 1. FEMORAL ARTERIAL AND VENOUS CARBON DIOXIDE TENSIONS AND CONCENTRATIONS DURING APNOEA IN NINE DOGS (MEAN ± STANDARD ERROR)

Time (min)	CO_2 tension (mm Hg)		CO_2 concentration difference (vol. per cent)
	Artery	Vein	Vein–artery
0	35 ± 4	40 ± 5	+2·1 ± 0·7
1	47 ± 4	44 ± 4	−1·4 ± 0·3
2	52 ± 5	47 ± 4	−2·5 ± 0·6
4	63 ± 6	53 ± 5	−3·3 ± 0·9
6	73 ± 6	60 ± 5	−3·3 ± 0·6

The carbon dioxide production of the dogs during the control period of artificial ventilation averaged 74 ml./min (standard error, ± 4). The mean blood flow in the femoral artery was 135 ml./min in the control period but decreased to an average of 92 ml./min during apnoea. Table 1 shows the carbon dioxide tensions and the venous minus the arterial carbon dioxide concentration differences observed during apnoea. During artificial ventilation the venous carbon dioxide tension exceeded the arterial by 5 mm of mercury while the carbon dioxide content of the vein was 2·1 vol. per cent greater than the artery. After 1 min of apnoea, these gradients were reversed and the venous carbon dioxide tension and concentration were less than those of the artery. At 6 min of apnoea, the average venous carbon dioxide tension was 13 mm of mercury less than that measured in the artery while the carbon dioxide concentration was 3·3 vol. per cent less.

The result of multiplying the average blood flow of the femoral artery by the mean venous–arterial carbon dioxide concentration differences shows that, during each minute of apnoea, muscle stores about 3 ml. of carbon dioxide produced elsewhere. This is about 4 per cent of the total production of carbon dioxide by the body each minute.

According to the multicompartment theory, carbon dioxide is stored in different tissue compartments, each with its own level of perfusion, metabolic rate and dissociation curve for carbon dioxide[2]. Ventilation changes produce rapid alterations in carbon dioxide content in richly perfused tissue such as the brain, but only slow changes in tissues with a large volume but a relatively poor perfusion such as muscle. The results of this study agree with the idea that muscle carbon dioxide reaches equilibrium sluggishly after a change in arterial carbon dioxide tension, thus producing the reversal of the usual venous–arterial concentration differences.

Induction of Hyperluteinization and Precocious Opening of the Vagina in Rats with a Transverse Cut in the Hypothalamus made shortly after Birth

THERE have been several reports that electrolytic lesions in the hypothalamus of infantile rats result in a precocious opening of the vagina and eventually in an early luteinization of the ovary[1-5]. It seems that in all cases when the ovaries of animals bearing hypothalamic lesions contained corpora lutea at puberty there was no more than the usual number of these bodies.

In a series of experiments, one transverse cut was made in the hypothalamus of thirty-six female random bred albino rats not more than 24 h old, and of six rats not more than 36 h old; a pointed, fine gauge steel needle (3·2 cm long and 0·5 mm in diameter) was used. (To make mechanical lesions in the hypothalamus of adult rats Halász and Gorski[6] used a double-edged knife fixed in the holder of a stereotaxic instrument.) The operation was performed by hand and without anaesthesia. The object of the experiment was to place the cut at about the level of the arcuate nucleus, transect all the antero-lateral connexions to the median basal hypothalamus and follow the effects of the lesion on the ovary for longer periods. In most of the animals the lesion involved the mammillary body.

Twelve sham operated rats and eighty-three normal animals served as controls. Into the sham operated rats we inserted the point of the needle far enough to perforate the tissues of the skull, carefully avoiding injury to the brain mass. Both experimental animals and controls were isolated from the males. The animals were killed at various times between 3·5 and 12 months old.

Thirteen rats had ovaries with scores of luteal bodies (Fig. 1). In eight of these the lesion extended posteriorly to include a portion of the mammillary body. The remaining five rats are still alive. In two animals, the lesion was made behind the origin of the pituitary stalk. The left ovary was removed from one of the latter on the day the vagina opened—the twenty-seventh day after birth. The ovary contained numerous medium sized follicles but no corpora lutea, and weighed 5·4 mg. When it was 10 months old this animal was killed. Its remaining ovary, which was enormously enlarged and weighed 200·8 mg, contained innumerable small and medium sized luteal bodies (Fig. 2*a* and *b*).

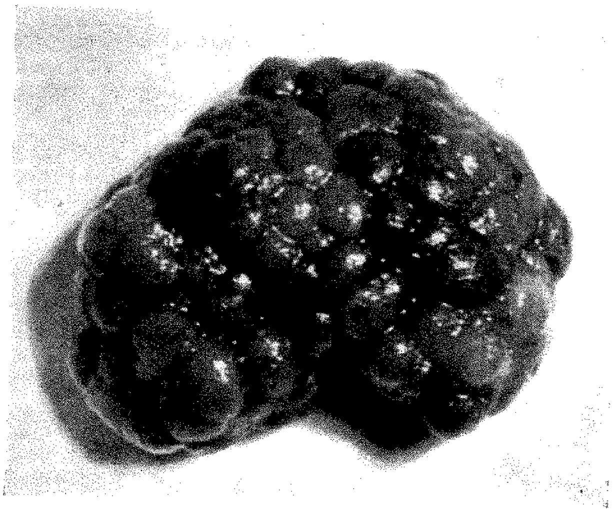

Fig. 1. Numerous corpora lutea in the ovary of a rat with a transverse cut through hypothalamus, killed 10 months after birth. The ovary at killing weighed 86·4 mg. (× 9.)

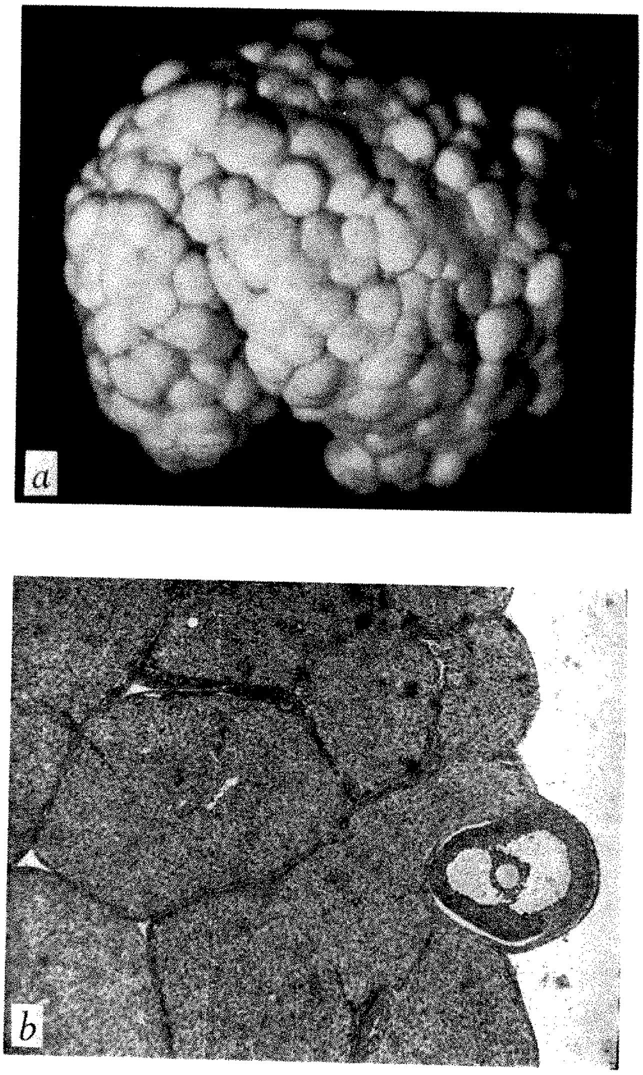

Fig. 2. *a*, "Innumerable" luteal bodies in the right ovary of a rat, operated as described, unilaterally ovariectomized on the day the vagina opened and killed when 10 months old. At death the ovary weighed 200·8 mg. (× 9.) *b*, Histological section through the same ovary, showing closely packed corpora lutea and one medium sized Graafian follicle. (× 42.)

The number of corpora lutea in the ovaries bearing a large number of them seems to remain constant for many months, although on the day of vaginal opening, if they were present, no more than the normal quota was to be found. This seems to be in agreement with the situation found by the authors already mentioned. The increase in number of corpora lutea seems therefore to be a result of repeated luteinization. Fresh corpora lutea had a normal histological structure.

Daily examinations of the vaginal smear for several weeks after the opening of the vagina revealed, in all the rats with supernumerary corpora lutea, repeated cycling periods, sometimes regular and sometimes irregular. The same can be said for the three rats from which daily vaginal smears were taken for 50 consecutive days beginning with the eighth month of their post-natal life. As well as numerous luteal bodies a few Graafian follicles, large and medium sized, were found in the ovaries of these rats. Burst follicles were also found in the ovaries of two animals. When confined with sexually mature males, these rats failed to mate.

Table 1 gives mean values (± standard deviation) for the age and body weight of experimental animals and for normal and sham operated controls on the day the vagina opened. As can be expected, there are individual varia-

Table 1

	No. of rats	Age (days)	Body weight (g)
With hypothalamic lesions	42	37·2 ± 5·98	75 ± 21·1
Sham operated	12	41·0 ± 2·38	100 ± 5·8
Normal controls	83	44·0 ± 4·75	108 ± 14·1

tions, but the precocity of the appearance of the phenomenon in the operated rats compared with normal controls is demonstrated both by the number of individuals (in six rats the vagina opened before they were 30 days old: in one on day 26, in one on day 27, and in four on day 29) and by the mean value for all rats. In normal rats we never observed this phenomenon earlier than day 32, regardless of season. Oddly enough, the opening of the vagina in sham operated rats was also significantly advanced (Table 1). A lag in the rate of gain of body weight regularly follows the injury to the hypothalamus, but this does not seem to affect seriously the precocity of the opening of the vagina. At death or after repeated laparotomies, that is, any time between 3 and 12 months after birth, the ovaries of all the rats in which the vagina opened precociously contained numerous corpora lutea, but this holds for an even larger number of rats in which the vagina opened within the interval characteristic for normal controls.

Continued Cleavage of Fertilized Bovine Ova in the Rabbit

FERTILIZED sheep ova have been shown to continue cleavage to the early blastocyst stage after transfer to the reproductive tract of the female rabbit[1]. This *in vivo* culture technique has facilitated the long distance transport of sheep ova[2]. This report suggests that a similar technique may be applied to cattle ova.

During 1967, cattle ova were recovered from the fallopian tubes of one hundred and forty cattle after superovulation treatment with placental gonadotrophins. Culture studies were made on five hundred of these ova. *In vitro* culture of ova in media based on cattle blood serum has not been successful. This agrees with previous reports[3]. Continued but limited cleavage to the 24-blastomere stage has been achieved in bovine follicular fluid. This supports the findings of other work[4].

In transferring cattle ova to the pseudo-pregnant rabbit, we have had limited success after using cattle serum as the recovery and transfer medium. We transferred one hundred and five fertilized ova using serum; fifty-one of these developed further. The maximum cleavage stage reached was nineteen blastomeres. We had better results after using bovine follicular fluid for recovery and transfer.

Seven sexually mature cattle were treated with 3,000 IU pregnant male serum gonadotrophin (PMSG) to induce superovulation on the sixteenth day of the oestrous cycle. The cattle were slaughtered 3 days after breeding and injection of 2,000 IU human chorionic gonadotrophin (HCG). Fifty-six of the fifty-nine ova recovered from these cattle were fertilized; thirty-two of these were used in transfers to seven pseudo-pregnant rabbits. Within 20 min of the slaughter of the cattle we began to recover the ova from their fallopian tubes using bovine follicular fluid. We then studied the ova within a temperature controlled cabinet (26·7° C).

Table 1. DEVELOPMENT OF CATTLE OVA IN THE RABBIT

Heifer identn.	Rabbit identn.	Fertilized ova Transferred	Fertilized ova Recovered	Initial cell stages	Final cell stages	Culture period (h)
98	*B*43	6	5	× 5 – × 10	4 × 80 + 1 × ruptured ovum	98
104	*B*7	6	1	× 4 – × 10	1 × 60 +	95·5
112	*B*9	4	2	× 6 – × 10	1 × 100 + 1 × 19	98
114	*B*5	4	3	× 8 – × 16	2 × 100 + 1 × degenerate ovum	94
124	*B*42	3	3	× 7 – × 8	3 × 90 +	94
129	*B*6	1	1	× 8	1 × 90 +	96
139	*B*28	8	4	× 5 – × 10	1 × 90 + 3 × 100 +	116·25

The fertilized ova were transferred in bovine follicular fluid to the ligated fallopian tubes of the rabbits, which had been injected 20–47 h previously with 30 IU of HCG. Four days later, the rabbit oviducts were removed and nineteen ova were recovered. Results of the transfers given are in Table 1. Seventeen ova had developed to the early blastocyst stage; in one instance the zona pellucida had ruptured and one ovum was degenerate. After recovery from the rabbits, the ova were fixed in acetic acid alcohol and stained with lacmoid solution. The high power of the microscope was used to estimate the number of nuclei in each blastocyst. On the basis of evidence for the early stages of the bovine ovum[5], the stages of cleavage reached by the cultured ova seem compatible with normal development.

This work is part of a research programme in cattle reproduction supported by the Department of Agriculture and Fisheries and the Agricultural Institute.

Effect on the Guinea-pig Taenia Coli of the Substitution of Strontium or Barium Ions for Calcium Ions

THE spontaneous discharge of the taenia coli of the guinea-pig is not inhibited by even a high concentration of tetrodotoxin (5×10^{-6} g/ml.), but it is blocked by a low concentration of ionic manganese (0·5 mM)[1], which is known to be a specific inhibitor of the calcium spikes in crustacean muscle[2] and also in barnacle muscle fibres[3]. These facts suggest that in the smooth muscle of taenia the membrane current during the action potential is carried principally by calcium ions. This would explain earlier findings that spike generation continues in solutions which are deficient in or free from sodium[4–6] and that

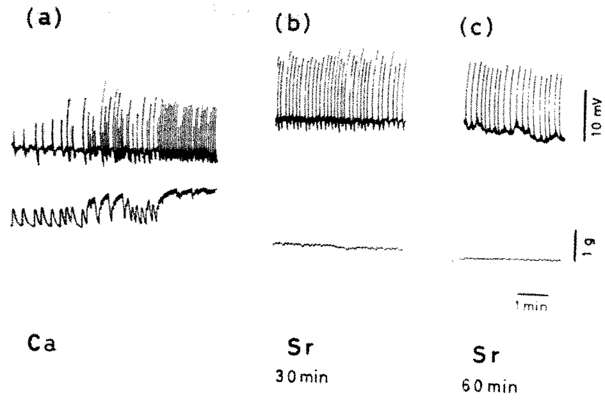

Fig. 1. Sucrose-gap records from the isolated taenia coli of the guinea-pig: spontaneous action potentials (upper tracings) and development of tension (lower tracings). Records were taken: (*a*) in normal Locke solution; (*b*) 30 min after replacement of calcium ions by an equivalent amount of strontium ions; (*c*) 60 min after the substitution. Note the decoupling of excitation and contraction in calcium-free medium which contains strontium.

spike height is almost independent of the external concentration of sodium ions[6]. Both the spontaneous activity and the potassium contracture are depressed by several transition metal ions such as manganese, nickel, cobalt or iron. The contraction induced by acetylcholine in normal Locke solution or in potassium-rich medium is also blocked by these divalent ions. The block is competitively antagonized by raising the external concentration of calcium, which supports the view that the entry of calcium ions across the membrane acts as a trigger for contraction[7].

We have examined the effect of substituting strontium or barium ions for calcium ions. Membrane potential and tension were recorded by a sucrose-gap method similar to that used by Bülbring and Burnstock[8]. The experiments were carried out on taenia coli of the guinea-pig at room temperature (23°–25° C). GEDTA (0·1 mM) was added to calcium-free solution to eliminate residual calcium ions.

Replacement of calcium ions in normal Locke solution (1·8 mM) with an equivalent amount of strontium or barium ions resulted in a depolarization of about 10 mV and an increase in spike frequency and tension. The tension, however, was not maintained for more than 20 min and it fell to less than one-tenth, in spite of the continuation of high frequency spike discharge (Fig. 1). Intracellular microelectrode measurements showed that a five-fold increase in the concentration of strontium or barium ions resulted in repolarization to almost the normal resting potential (stabilization) and in prolongation of the spike duration (probably because of a decrease of potassium permeability). In these media, the relation between spike frequency and tension was variable, but nearly normal tension was obtained in some cases.

The decoupling of excitation and contraction in calcium-free solution containing other alkaline-earth metal ions is understandable if it is assumed that the calcium ions which entered the cell during an action potential exert a direct influence on the contractile proteins and that other alkaline-earth metal ions have a relatively weak effect on the smooth muscle actomyosin system. Information on the sensitivity of intestinal smooth muscle proteins to divalent cations is not yet available, but according to S. Ebashi (personal communication), strontium and barium ions have very little effect on the superprecipitation of chicken gizzard actomyosin—one-twentieth and one-two-hundredth of that of calcium ions, respectively. This indicates that strontium and barium ions cannot be effective substitutes for calcium ions in triggering contraction. This is probably also true with the taenia coli of the guinea-pig, so the dissociation of spike discharge from the development of tension strongly supports the view that the calcium which carries the electrical current during the action potentials acts directly on the contractile mechanism. The possibility still remains, however, that the release of calcium from intracellular binding sites plays some part in contraction which has been demonstrated for the tonic phase of the potassium contracture[9].
